description

The 'ABTE16246 devices are 11-bit noninverting transceivers designed for asynchronous two-way communication between buses. These devices have open-collector and 3-state outputs. They allow data transmission from the A bus to the B bus or from the B bus to the A bus, depending on the logic level at the direction-control (DIR) input. The output-enable ($\overline{OE}$) input can be used to disable the device so that the buses are effectively isolated. When $\overline{OE}$ is low, the device is active.

The B port has an equivalent 25-Ω series output resistor to reduce ringing. Active bus-hold inputs on the B port hold unused or floating inputs at a valid logic level.

The A port provides for the precharging of the outputs via V_{CC}BIAS, which establishes a voltage between 1.3 V and 1.7 V when V_{CC} is not connected.

The SN54ABTE16246 is characterized for operation over the full military temperature range of –55°C to 125°C. The SN74ABTE16246 is characterized for operation from –40°C to 85°C.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

† Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
NOTES: 1. The input and output negative-voltage ratings may be exceeded if the input and output clamp-current ratings are observed.
            2. The package thermal impedance is calculated in accordance with JESD 51.

## PARAMETER MEASUREMENT INFORMATION
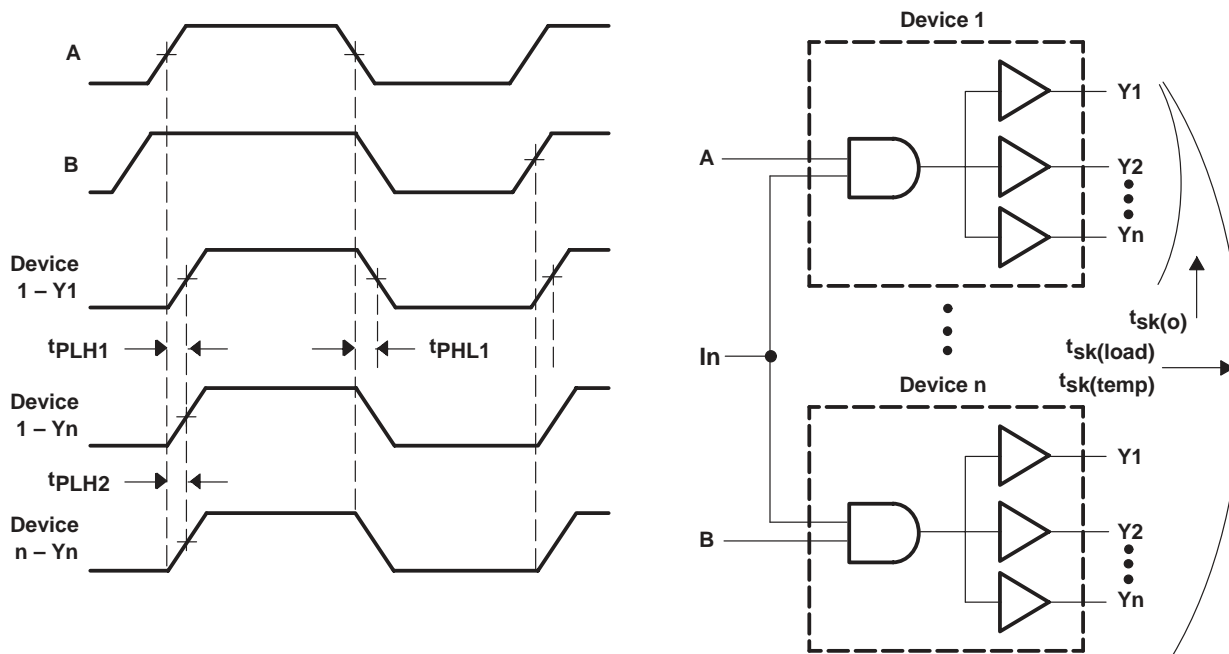

NOTES: A. Pulse skew, $t_{sk(p)}$, is defined as the difference in propagation delay times t_{PLH1} and t_{PHL1} on the same terminal at identical operating conditions.
   B. Output skew, $t_{sk(o)}$, is defined as the difference in propagation delay of any two outputs of the same device switching in the same direction (e.g., $|t_{PLH1} - t_{PLH2}|$) .
   C. Temperature skew, $t_{sk(temp)}$, is the output skew of two devices, both having the same value of $V_{CC} \pm 1\%$ and with package temperature differences of 20°C.
   D. Load skew, $t_{sk(load)}$, is measured with R_X in Figure 2 at 13 Ω for one unit and 56 Ω for the other unit.
