¹FEATURES DESCRIPTION

The ADS7945/6 are 14-bit, 2 MSPS analog-to-digital converters (ADCs), with differential and single-ended • **14-Bit, Pin-Compatible with 8/10/12-bit** inputs, respectively. The devices operate at a 2 **[ADS7947/8/9](http://focus.ti.com/docs/prod/folders/print/ads7947.html) Family (ADS7946)** MSPS sample rate with a standard 16-clock data frame. The devices feature both outstanding dc precision and excellent dynamic performance; the – **SNR: 84 dB (ADS7945)** ADS7946 is pin-compatible with the 8/10/12-bit – **No Missing Codes** ADS7947/8/9 devices. The devices include a two-channel input multiplexer and a low-power **Low Power: Successive approximation register (SAR) ADC with** successive approximation register (SAR) ADC with an inherent sample-and-hold (S/H) input stage.

- Auto Power-Down at Lower Speeds: The ADS7945/6 support a wide analog supply range that allows the full-scale input range to extend to $±5$ V – **7.2 mW at 500 kSPS** differential or 5 V single-ended. A simple SPI™, with a digital supply that can operate as low as 1.65 V, – **0.3 mW at 20 kSPS** allows for easy interfacing to a wide variety of digital controllers. Automatic power-down can be enabled **Wide Supply Range:**

— **Analog: 2.7 V to 5.25 V Example 1 We a supply the speeds to dramatically**

The power consumption reduce power consumption.

– **Digital: 1.65 V to AVDD** Offered in a tiny 3 mm [×] 3 mm QFN package, the • **Simple Serial Interface (SPI)** ADS7945/6 are fully specified over the extended • **Fully Specified from** –**40**°**C to +125**°**C** temperature range of –40°C to +125°C and are suitable for a wide variety of data acquisition **Finy Footprint: 3 mm × 3 mm QFN** applications where high performance, low power, and small package size are key. **APPLICATIONS**

SBAS539B –JUNE 2011–REVISED SEPTEMBER 2011 **www.ti.com**

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

FAMILY AND ORDERING INFORMATION(1)

(1) For the most current package and ordering information, see the Package Option Addendum at the end of this document, or visit the device product folder at [www.ti.com.](http://www.ti.com)

ABSOLUTE MAXIMUM RATINGS(1)

Over operating free-air temperature range, unless otherwise noted.

(1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under electrical characteristics is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS: ADS7945 (Differential)

Minimum/maximum specifications at $T_A = -40^{\circ}C$ to +125°C, AVDD = 2.7 V to 5.25 V, DVDD = 1.65 V to AVDD, input common-mode = $V_{REF}/2 \pm 0.2$, and $f_{SAMPLE} = 2$ MSPS, unless otherwise noted.

Typical specifications at $T_A = +25^{\circ}C$, AVDD = 5 V, DVDD = 1.8 V, input common-mode = $V_{REF}/2 \pm 0.2$, and $f_{SAMPLE} = 2$ MSPS.

(1) Ideal input span; does not include gain or offset error.

(2) Refer to the [Input Common-Mode Range](#page-32-0) section in Application Information.

(3) Refer to [Figure 76](#page-24-0) for sampling circuit details.

(4) LSB means least significant bit.

(5) Measured relative to an ideal full-scale input.

(6) Ensured by simulation.
(7) Calculated on the first r

Calculated on the first nine harmonics of the input frequency.

(8) Indicates signal bandwidth for undersampling applications.

ELECTRICAL CHARACTERISTICS: ADS7945 (Differential) (continued)

Minimum/maximum specifications at $T_A = -40^{\circ}C$ to +125°C, AVDD = 2.7 V to 5.25 V, DVDD = 1.65 V to AVDD, input common-mode = $V_{REF}/2 \pm 0.2$, and $f_{SAMPLE} = 2$ MSPS, unless otherwise noted.

Typical specifications at T_A = +25°C, AVDD = 5 V, DVDD = 1.8 V, input common-mode = V_{REF}/2 ± 0.2, and f_{SAMPLE} = 2 MSPS.

(9) DVDD consumes only dynamic current. $I_{DVDD} = C_{LOAD} \times DVD \times number$ of 0→1 transitions in SDO × f_{SAMPLE}.
This is a load-dependent current and there is no DVDD current when the output is not toggling.

TYPICAL CHARACTERISTICS: ADS7946 (continued)

At T_A = +25°C, AVDD = 5 V, DVDD = 1.8 V, V_{REF} = 2.5 V, and f_{SAMPLE} = 2 MSPS, unless otherwise noted.

OVERVIEW

The ADS7945 and ADS7946 are 14-bit, miniature, dual-channel, low-power SAR ADCs. The ADS7945 is a differential input device and the ADS7946 is a single-ended device with ground sensing input. These devices feature very low power consumption at rated speed. The PDEN pin enables an auto power-down mode that further reduces power consumption at lower speeds.

MULTIPLEXER AND ADC INPUT

The ADS7945/46 devices feature differential/single-ended inputs respectively with a double-pole, double-throw multiplexer. The analog input circuit shown in [Figure 75](#page-23-0) is similar for for ADS7945 and ADS7946.

The ADS7945 features a differential input. Each of the positive (AINxP) and negative (AINxN) inputs can swing from $-V_{REF}/2$ to $V_{REF}/2$ around the common-mode voltage (AINxP + AINxN)/2 so that AINxP and AINxN swing in opposite directions equally from common-mode voltage (differential input swing V_{AINXP} – V_{AINX} ranges from $-V_{REF}$ to $+V_{REF}$). The ADC converts the difference in voltage: $V_{AINXP} - V_{AINXN}$. This feature allows the devices to reject the common-mode noise in the input signal.

For the ADS7946, the ground sense inputs (AINxGND) can accept swings of ± 0.2 V whereas the inputs (AINx) allow signals in the range of 0 V to V_{REF} over the ground sense input. The ADC converts the difference in voltage: $V_{AINx} - V_{AINxGND}$. This feature can be used in multiple ways. For example, two signals can be connected from different sensors with unequal ground potentials (within ±0.2 V) to a single ADC. The ADC rejects the common-mode offset and noise. This feature also allows the use of a single-supply op amp. The signal and the AINxGND input can be offset by +0.2 V, which provides the ground clearance required for a single-supply op amp.

[Figure 75](#page-23-0) shows the electrostatic discharge (ESD) diodes to supply and ground at every analog input. Make sure that these diodes do not turn on by keeping the supply voltage within the specified input range.

Figure 75. Analog Inputs

[Figure 76](#page-24-0) shows an equivalent circuit of the multiplexer and ADC sampling stage. See the [Application](#page-32-1) [Information](#page-32-1) section for details on the driving circuit. The positive and negative/ground sense inputs are separately sampled on 32 pF sampling capacitors. The multiplexer and sampling switches are represented by an ideal switch in series with a 12 Ω resistance. Note that this is dc resistance and can be used for step-settling calculations (do not use the RC values shown in [Figure 76](#page-24-0) for 3 dB bandwidth calculations for undersampling applications). During sampling, the devices connect the 32 pF sampling capacitor to the ADC driver. This connection creates a glitch at the device input. It is recommended to connect a capacitor across the AINxP and AINxN terminals or AINx and AINxGND terminals to reduce this glitch for the ADS7945 or ADS7946, respectively. A driving circuit must have sufficient bandwidth to settle this glitch within the acquisition time.

Figure 76. Input Sampling Stage Equivalent Circuit

[Figure 77](#page-24-1) shows a timing diagram for the ADC analog input channel selection. As shown in [Figure 77](#page-24-1), the CH SEL signal selects the analog input channel to the ADC. CH SEL = 0 selects channel 0 and CH SEL = 1 selects channel 1. It is recommended not to toggle the CH SEL signal during an ADC acquisition phase until the device sees the first valid SCLK rising edge after the device samples the analog input. If CH SEL is toggled during this period, it can cause erroneous output code because the device might see unsettled analog input.

CH SEL can be toggled at any time during the window specified in [Figure 77](#page-24-1); however, it is recommended to select the desired channel after the first SCLK rising edge and before the second SCLK rising edge. This timing ensures that the multiplexer output is settled before the ADC starts acquisition of the analog input.

Figure 77. ADC Analog Input Channel Selection

REFERENCE

The ADS7945/6 use an external reference voltage during the conversion of a sampled signal. The devices switch the capacitors used in the conversion process to the reference terminal during conversion. The switching frequency is the same as the SCLK frequency. It is necessary to decouple the REF terminal to REFGND with a 1 µF ceramic capacitor in order to get the best noise performance from the device. The capacitor must be placed closest to these pins. The reference input can be driven with the [REF50xx](http://focus.ti.com/docs/prod/folders/print/ref5010.html) series precision references from TI. [Figure 78](#page-25-0) shows a typical reference driving circuit.

Sometimes it is convenient to use AVDD as a reference. The ADS7945/6 allow reference ranges up to AVDD. However, make sure that AVDD is well-bypassed and that there is a separate bypass capacitor between REF and REFGND.

(1) Select the appropriate device as described by the required reference value. For example, select the [REF5040](http://focus.ti.com/docs/prod/folders/print/ref5040.html) for a 4 V reference, the [REF5030](http://focus.ti.com/docs/prod/folders/print/ref5030.html) for a 3 V reference, and the [REF5025](http://focus.ti.com/docs/prod/folders/print/ref5025.html) for a 2.5 V reference. Ensure that (AVDD – REF) > 0.2 V so that the REF50xx functions properly.

Figure 78. Typical Reference Driving Circuit

CLOCK

The ADS7945/6 use SCLK for conversions (typically 40 MHz). A lower frequency SCLK can be used for applications that require sample rates less than 2 MSPS. However, it is better to use a 40 MHz SCLK and slow down the device speed by choosing a lower frequency for \overline{CS} , which allows more acquisition time. This configuration relaxes constraints on the output impedance of the driving circuit. Refer to the [Application](#page-32-1) [Information](#page-32-1) section for calculation of the driving circuit output impedance.

ADC TRANSFER FUNCTION

The ADS7945 is a differential input device and the ADS7946 is a single-ended input device. This section describes the transfer characteristics for both devices.

The ADS7945 output is in twos compliment format. [Figure 79](#page-26-0) shows the ideal transfer characteristics for these devices. Here, full-scale range for the ADC input (AINxP – AINxN) is equal to twice the reference input voltage to the ADC 2 \times (V_{REF}). 1 LSB is equal to 2 \times (V_{REF}/2^N), where N is the resolution of the ADC (N = 14 for the ADS7945). The differential input of the ADC is bipolar around the common-mode voltage (AINxP + AINxN)/2 and has a range of positive FSR (+ V_{REF}) to negative FSR (- V_{REF}).

Figure 79. ADS7945 Transfer Characteristics

The ADS7946 output is in straight binary format. [Figure 80](#page-27-0) shows ideal transfer characteristics for this device. Here, FSR is the full-scale range for the ADC input (AINx – AINxGND) and is equal to the reference input voltage to the ADC (V_{REF}). 1 LSB is equal to (V_{REF}/2^N), where *N* is the resolution of the ADC (N = 14 for the ADS7946).

Figure 80. ADS7946 Transfer Characteristics

DEVICE OPERATION

The ADS7945/6 operate with either a 16-clock frame or 32-clock frame for ease of interfacing with the host processor.

16-CLOCK FRAME

[Figure 81](#page-28-0) shows the devices operating in 16-clock mode. This mode is the fastest mode for device operation. In this mode, the devices output data from previous conversions while converting the recently sampled signal.

As shown in [Figure 81](#page-28-0), the ADS7945/6 start acquisition of the analog input from the 16th falling edge of SCLK. The device samples the input signal on the $\overline{\text{CS}}$ falling edge. SDO comes out of 3-state and the device outputs the MSB on the CS falling edge. The device outputs the next lower SDO bits on every SCLK falling edge after it has first seen the SCLK rising edge. The data correspond to the sample and conversion completed in the previous frame. During a \overline{CS} low period, the device converts the recently sampled signal. It uses SCLK for conversions. Conversion is complete on the 16th SCLK falling edge. CS can be high at any time after the 16th SCLK falling edge (see the Parameter Measurement Information for more details). The CS rising edge after the 16th SCLK falling edge and before the 29th SCLK falling edge keeps the device in the 16-clock data frame. The device output goes to 3-state when \overline{CS} is high. It is also permissible to stop SCLK after the device has seen the 16th SCLK falling edge.

Figure 81. ADS7945/6 Operating in 16-Clock Mode without Power-Down (PDEN = 0)

32-CLOCK FRAME

[Figure 82](#page-28-1) shows the devices operating in 32-clock mode. In this mode, the devices convert and output the data from the most recent sample before taking the next sample.

CS can be held low past the 16th falling edge of SCLK. The devices continue to output recently converted data starting with the 16th SCLK falling edge. If \overline{CS} is held low until the 30th SCLK falling edge, then the devices detect 32-clock mode. Note that the device data from recent conversions are already output with no latency before the 30th SCLK falling edge. Once 32-clock mode is detected, the device outputs 16 zeros during the next conversion (in fact, for the first 16 clocks), unlike 16-clock mode where the devices output the previous conversion result. SCLK can be stopped after the devices have seen the 30th falling edge with CS low.

CONVERSION ABORT

For some event triggered applications such as latching position of absolute position sensor on marker or homing pulse, it is essential to abort ongoing conversion on event and quickly start fresh acquisition. ADS794X features conversion abort function. CS high during conversion (during first 16 clocks) will abort ongoing conversion and start fresh acquisition. Device will sample acquired signal during \overline{CS} high period on falling edge of \overline{CS} and will start conversion normally, however data on SDO (conversion results from aborted frame) will not be valid.

For example if conversion is aborted during 'nth' frame and $(n+1)$ is first valid frame after conversion abort. SDO data during frame number (n+1) (corresponding to nth conversion) will not be valid. Conversion results for sample and conversion during frame number $(n+1)$ will be available in frame number $(n+2)$.

POWER-DOWN

The ADS7945/6 devices offer an easy-to-use power-down feature available through a dedicated PDEN pin (pin 12). A high level on PDEN at the CS rising edge enables the power-down mode for that particular cycle. [Figure 83](#page-29-0) to [Figure 85](#page-31-1) illustrate device operation with power-down in both 32-clock and 16-clock mode.

Many applications must slow device operation. For speeds below approximately 500 kSPS, it is convenient to use 32-clock mode with power-down. This configuration results in considerable power savings.

As shown in [Figure 83](#page-29-0), PDEN is held at a logic '1' level. Note that the device looks at the PDEN status only at the $\overline{\text{CS}}$ rising edge; however, for continuous low-speed operation, it is convenient to continuously hold PDEN = 1. The devices detect power-down mode on the \overline{CS} rising edge with PDEN = 1.

Figure 83. Operation with a 32-Clock Frame in Power-Down Mode (PDEN = 1)

On the CS falling edge, the devices start normal operation as previously described. The devices complete conversions on the 16th SCLK falling edge. The devices enter the power-down state immediately after

conversions complete. However, the devices can still output data as per the timings described previously. The devices consume dynamic power-down current (I_{PD-DYNAMIC}) during data out operations. It is recommended to stop the clock after the 32nd SCLK falling edge to further save power down to the static power-down current level (I_{PD-STATIC}). The devices power up again on the SCLK rising edge. However, they require an extra 1 µs to power up completely. $\overline{\text{CS}}$ must be high for the 1 μ s + t_{ACQ} (min) period.

In some applications, data collection is accomplished in burst mode. The system powers down after data collection. 16-clock mode is convenient for these applications. [Figure 84](#page-31-0) and [Figure 85](#page-31-1) detail power saving in 16-clock burst mode.

Figure 84. Entry Into Power-Down with 16-Clock Burst Mode

As shown in [Figure 84,](#page-31-0) the two frames capturing the N–1 and Nth samples are normal 16-clock frames. Keeping $PDEN = 1$ before the \overline{CS} rising edge in the next frame ensures that the devices detect the power-down mode. Data from the Nth sample are read during this frame. It is expected that the Nth sample represents the last data of interest in the burst of conversions. The devices enter the power-down state after the end of conversions. This is the 16th SCLK falling edge. It is recommended to stop the clock after the 16th SCLK falling edge. Note that it is mandatory not to have more than 29 SCLK falling edges during the CS low period. This limitation ensures that the devices remain in 16-clock mode.

The devices remain in a power-down state as long as \overline{CS} is low. A \overline{CS} rising edge with PDEN = 0 brings the devices out of the power-down state. It is necessary to ensure that the CS high time for the first sample after power up is more than 1 μs + t_{ACQ} (min).

Figure 85. Exit From Power-Down with 16-Clock Burst Mode

APPLICATION INFORMATION: ADS7945

The ADS7945 employs a sample-and-hold stage at the input; see [Figure 76](#page-24-0) for a typical equivalent circuit of a sample-and-hold stage. The device connects a 32 pF sampling capacitor during sampling. This configuration results in a glitch at the input terminals of the device at the start of the sample. The external circuit must be designed in such a way that the input can settle to the required accuracy during the sampling time chosen. [Figure 86](#page-32-2) shows a typical driving circuit for the analog inputs.

Figure 86. Typical Input Driving Circuit for the ADS7945

The 470 pF capacitor across the AINxP and AINxN terminals decouples the driving op amp from the sampling glitch. It is recommended to split the series resistance of the input filter in two equal values as shown in [Figure 86](#page-32-2). It is recommended that both input terminals see the same impedance from the external circuit. The low-pass filter at the input limits noise bandwidth of the driving op amps. Select the filter bandwidth so that the full-scale step at the input can settle to the required accuracy during the sampling time. [Equation 1,](#page-32-3) [Equation 2](#page-32-4), and [Equation 3](#page-32-5) are useful for filter component selection.

Sampling Time Filter Time Constant $(t_{AU}) = \frac{1}{\sqrt{\frac{3}{1-1}} \cdot \frac{1}{\sqrt{1-1}}}$

Where:

Settling resolution is the accuracy in LSB to which the input needs to settle. A typical settling resolution for the 14-bit device is 15 or 16. (1)

Also, make sure the driving op amp bandwidth does not limit the signal bandwidth below filter bandwidth. In many applications, signal bandwidth may be much lower than filter bandwidth. In this case, an additional low-pass filter may be used at the input of the driving op amp. This signal filter bandwidth can be selected in accordance with the input signal bandwidth.

INPUT COMMON-MODE RANGE

The AIN+ and AIN– inputs to the ADS7945 should typically vary between 0 V and V_{REF} with a common-mode of V_{REF}/2. The ADS7945 offers excellent CMRR which makes it possible to achieve close to the rated performance of the converter even in cases where the common-mode input is not well-controlled. The device can accept a \pm 200 mV variation in the common-mode voltage at any VDD/V_{RFF} combination allowing use of the entire ADC signal range $(-V_{REF}$ to $+V_{REF}$ differentially).

DRIVING AN ADC WITHOUT A DRIVING OP AMP

For some low input signal bandwidth applications, such as battery power monitoring or mains monitoring, it is not required to operate an ADC at high sampling rates. In fact, it is desirable to avoid using a driving op amp from a cost perspective. In these cases, the ADC input sees the impedance of the signal source (such as a battery or mains transformer). This section elaborates the effects of source impedance on sampling frequency.

[Equation 1](#page-32-3) can be rewritten as [Equation 4](#page-33-0):

Sampling Time = Filter Time Constant × Settling Resolution × ln(2) (4)

As shown in [Figure 87](#page-33-1), it is recommended to use a bypass capacitor across the positive and negative ADC input terminals.

Figure 87. Driving an ADS7945 ADC Without a Driving Op Amp

Source impedance (2 × R_{SOLRCE} + 2 × R_{S}) with (C_{BYPASS} + C_{SAMPLE}) acts as a low-pass filter with [Equation 5](#page-33-2): Filter Time Constant = $2 \times (R_{\text{SOURCE}} + R_S) \times (C_{\text{BYPASS}} + C_{\text{SAMPLE}})$ where:

 C_{SAMPLE} is the internal sampling capacitance of the ADC (equal to 32 pF). (5)

[Table 4](#page-34-0) lists the recommended bypass capacitor values and the filter time constant for different source resistances. It is recommended to use a 10 pF bypass capacitor, at minimum. [Table 4](#page-34-0) assumes R_S = 5 Ω; however, depending on the application, R_S can be chosen to be 0 Ω. In this case, there is an extra margin of 5 Ω for R_{SOLIRCF} .

Typically, settling resolution is selected as (ADC resolution + 2). For the ADS7945 (14-bit) the ideal settling resolution is 16. Using [Equation 2](#page-32-4) and [Equation 3,](#page-32-5) the sampling time can be easily determined for a given source impedance and allows 80 ns of sampling time for a 14-bit ADC with 7.2 ns of filter time constant, which matches the ADS7945 specifications. For net source impedance (2 × (R_{SOURCE} + R_S)) above 171 Ω, the filter time constant continues to increase beyond the 7.2 ns required for an 80 ns sampling time. This increment increases the minimum permissible sampling time for 14-bit settling and the device must be operated at a lower sampling rate.

The device sampling rate can be maximized by using a 40 MHz clock even for lower throughputs. [Table 5](#page-34-1) shows typical calculations for the ADS7945.

2 × $R_{\text{SOWRCE}}(\Omega)$	C_{BYPASS} (pF)	SAMPLING TIME, t_{ACQ} (ns)	CONVERSION TIME, t_{CONV} (ns)	CYCLE TIME, t_{ACQ} + t _{CONV} (ns)	SAMPLING RATE (MSPS)
161	10	80	420 (with 40 MHz clock)	500	2
500	10	235	420 (with 40 MHz clock)	655	1.5
1000	10	468	420 (with 40 MHz clock)	888	1.1
5000	10	2331	420 (with 40 MHz clock)	2751	0.4

Table 5. Sampling Frequency versus Source Impedance for the ADS7945 (14-Bit)

It is necessary to allow 1000 ns additional sampling time over what is shown in [Table 5](#page-34-1) if PDEN (pin 12) is set high.

APPLICATION INFORMATION: ADS7946

The ADS7946 employs a sample-and-hold stage at the input; see [Figure 76](#page-24-0) for a typical equivalent circuit of a sample-and-hold stage. The device connects a 32 pF sampling capacitor during sampling. This configuration results in a glitch at the input terminals of the device at the start of the sample. The external circuit must be designed in such a way that the input can settle to the required accuracy during the sampling time chosen. [Figure 88](#page-35-0) shows a typical driving circuit for the analog inputs.

Figure 88. Typical Input Driving Circuit For the ADS7946

The 470 pF capacitor across the AINx and AINxGND terminals decouples the driving op amp from the sampling glitch. It is recommended to split the series resistance of the input filter in two equal values, as shown in [Figure 88](#page-35-0). It is recommended that both input terminals see the same impedance from the external circuit. The low-pass filter at the input limits noise bandwidth of the driving op amp. Select the filter bandwidth so that the full-scale step at the input can settle to the required accuracy during the sampling time. [Equation 6,](#page-35-1) [Equation 7](#page-35-2), and [Equation 8](#page-35-3) are useful for filter component selection.

Filter Time Constant
$$
(t_{AU}) = \frac{\text{Sampling Time}}{\text{Setting Resolution} \times \text{In(2)}}
$$

where:

Settling resolution is the accuracy in LSB to which the input must settle. A typical settling resolution for the 14-bit device is 15 or 16. $\qquad \qquad (6)$

Filter Time Constant
$$
(t_{AU}) = R \times C
$$

Filter Bandwidth =
$$
\frac{1}{2 \times \pi \times t_{\text{AU}}}
$$

(8)

(7)

Also, make sure the driving op amp bandwidth does not limit the signal bandwidth below filter bandwidth. In many applications, signal bandwidth may be much lower than filter bandwidth. In this case, an additional low-pass filter may be used at the input of the driving op amp. This signal filter bandwidth can be selected in accordance with the input signal bandwidth.

[ADS7945](http://focus.ti.com/docs/prod/folders/print/ads7945.html) [ADS7946](http://focus.ti.com/docs/prod/folders/print/ads7946.html)

DRIVING AN ADC WITHOUT A DRIVING OP AMP

For some low input signal bandwidth applications, such as battery power monitoring or mains monitoring, it is not required to operate an ADC at high sampling rates. In fact, it is desirable to avoid using a driving op amp from a cost perspective. In this case, the ADC input sees the impedance of the signal [Equation 4](#page-33-0) source (such as a battery or mains transformer). This section elaborates the effects of source impedance on sampling frequency.

[Equation 6](#page-35-1) can be rewritten as [Equation 9](#page-36-0):

Sampling Time = Filter Time Constant × Settling Resolution × ln(2) (9)

As shown in [Figure 89](#page-36-1), it is recommended to use a bypass capacitor across the positive and negative ADC input terminals.

Figure 89. Driving an ADS7946 ADC Without a Driving Op Amp

Source impedance ($R_{\text{SOWRCE}} + R_{\text{S}}$) with ($C_{\text{BYPASS}} + C_{\text{SAMPLE}}$) acts as a low-pass filter with [Equation 10:](#page-36-2) Filter Time Constant = $(R_{\text{SOLRCE}} + R_S) \times (C_{\text{BYPASS}} + C_{\text{SAMPLE}})$ Where:

 C_{SAMPLE} is the internal sampling capacitance of the ADC (equal to 32 pF). (10)

[Table 6](#page-37-0) lists the recommended bypass capacitor values and the filter time constant for different source resistances. It is recommended to use a 10 pF bypass capacitor (minimum).

Table 6. Filter Time Constant versus Source Resistance

Typically, settling resolution is selected as (ADC resolution + 2). For the ADS7946 (14-bit) the ideal settling resolution is 16. Using equations [Equation 7](#page-35-2) and [Equation 8](#page-35-3), the sampling time can be easily determined for a given source impedance and allows 80 ns of sampling time for a 14-bit ADC with 7.2 ns of filter time constant, which matches the ADS7946 specifications. For source impedance above 166 Ω, the filter time constant continues to increase beyond the 7.2 ns required for an 80 ns sampling time. This increment increases the minimum permissible sampling time for 14-bit settling and the device must be operated at a lower sampling rate.

The device sampling rate can be maximized by using a 40 MHz clock even for lower throughputs. [Table 7](#page-37-1) shows typical calculations for the ADS7946.

Table 7. Sampling Frequency versus Source Impedance for the ADS7946 (14-Bit)

It is necessary to allow 1000 ns additional sampling time over what is shown in [Table 7](#page-37-1) if PDEN (pin 12) is set high.

PCB LAYOUT/SCHEMATIC GUIDELINES: ADS7945

The ADS7945 is a mixed-signal device. For maximum performance, proper decoupling, grounding, and proper termination of digital signals are essential. [Figure 90](#page-38-0) shows the essential components around the ADC. All capacitors shown are ceramic. These decoupling capacitors must be placed close to the respective signal pins.

There is a 47 Ω source series termination resistor shown on the SDO signal. This resistor must be placed as close to pin 15 as possible. Series terminations for SCLK and \overline{CS} must be placed close to the host.

Figure 90. Recommended ADS7945 ADC Schematic

A common ground plane for both analog and digital often enables better results. Typically, the second PCB layer is the ground plane. The ADC ground pins are returned to the ground plane through multiple vias (PTH). It is a good practice to place analog components on one side and digital components on other side of the ADC (or ADCs). All signals must be routed, assuming there is a split ground plane for analog and digital. Furthermore, it is better to split the ground initially during layout. Route all analog and digital traces so that the traces see the respective ground all along the second layer. Then short both grounds to form a common ground plane. [Figure 91](#page-39-0) shows a typical layout around the ADC.

Figure 91. Recommended ADS7945 ADC Layout (Only top layer is shown; second layer is common ground for analog and digital)

PCB LAYOUT/SCHEMATIC GUIDELINES: ADS7946

The ADS7946 is a mixed-signal device. For maximum performance, proper decoupling, grounding, and proper termination of digital signals are essential. [Figure 92](#page-40-0) shows the essential components around the ADC. All capacitors shown are ceramic. These decoupling capacitors must be placed close to the respective signal pins.

There is a 47 Ω source series termination resistor shown on the SDO signal. This resistor must be placed as close to pin 15 as possible. Series terminations for SCLK and \overline{CS} must be placed close to the host.

Figure 92. Recommended ADS7946 ADC Schematic

A common ground plane for both analog and digital often enables better results. Typically, the second PCB layer is the ground plane. The ADC ground pins are returned to the ground plane through multiple vias (PTH). It is a good practice to place analog components on one side and digital components on other side of the ADC (or ADCs). All signals must be routed, assuming there is a split ground plane for analog and digital. Furthermore, it is better to split the ground initially during layout. Route all analog and digital traces so that the traces see the respective ground all along the second layer. Then short both grounds to form a common ground plane. [Figure 93](#page-41-0) shows a typical layout around the ADC.

PACKAGING INFORMATION

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures. "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the ≤ 1000 ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
