

20-BIT SERIAL TO PARALLEL CONVERTER

■ GENERAL DESCRIPTION

The **NJU3718** is a 20-bit serial to parallel converter especially applying to MPU output expander.

The effective output assignment of MPU is available as the connection between **NJU3718** and MPU using only 4 lines.

The serial data synchronizing with 5MHz or more clock can be input to the serial data input terminal and the data are output from parallel output buffer through serial in parallel out shift register and parallel data latches.

Furthermore, the **NJU3718** outputs the serial data from SO terminal through the shift register. Therefore, it connects with other SIPO ICs like as NJU3711 in cascade for expanding the parallel conversion outputs.

The hysteresis input circuit realizes wide noise margin and the high drive-ability output buffer (25mA) can drive LED directly.

■ FEATURES

- 20-Bit Serial In Parallel Out
- Hysteresis Input 0.5V typ
- Operating Voltage 5V±10%
- Maximum Operating Frequency 5MHz and more
- Output Current 25mA
- C-MOS Technology
- Package Outline SDIP28/SOP28/SDMP30

■ FUNCTIONAL DESCRIPTION

(1) Reset

When the "L" level is input to the $\overline{\text{CLR}}$ terminal, all latches are reset and all of parallel conversion output are "L" level.

Normally, the $\overline{\text{CLR}}$ terminal should be "H" level.

(2) Data Transmission

In the $\overline{\text{STB}}$ terminal is "H" level and the clock signals are inputted to the CLK terminal, the serial data into the DATA terminal are shifted in the shift register synchronizing at a rising edge of the clock signal.

When the $\overline{\text{STB}}$ terminal is changed to "L" level, the data in the shift register are transferred to the latches.

Even if the $\overline{\text{STB}}$ terminal is "L" level, the input clock signal shifts the data in the shift register, therefore, the clock signal should be controlled for data order.

(3) Cascade Connection

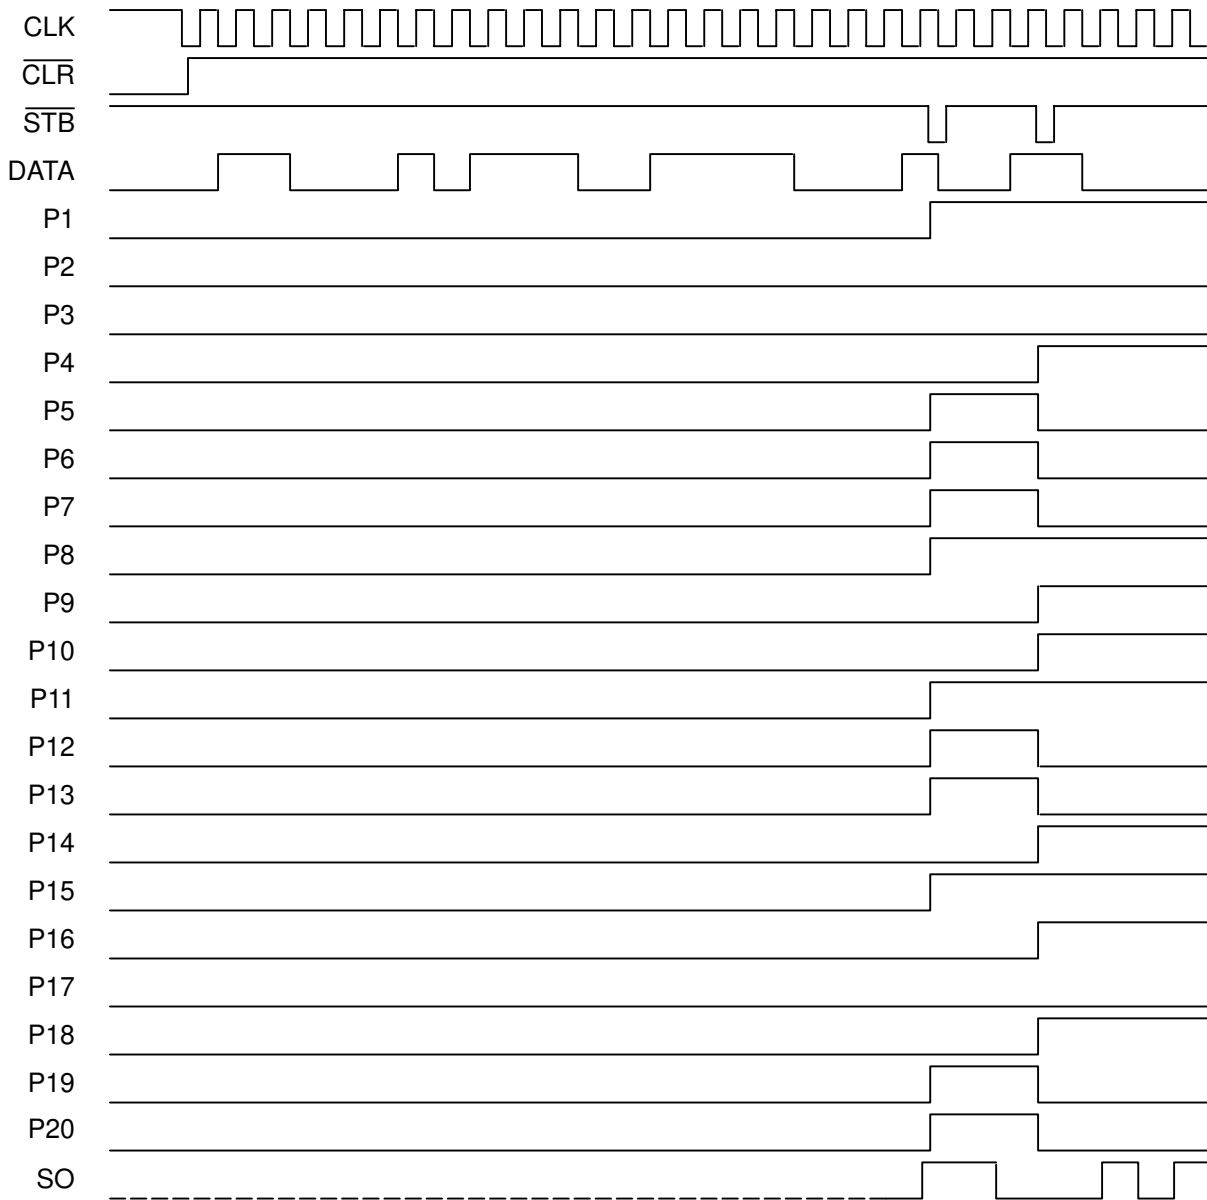

The serial data input from DATA terminal is output from the SO terminal through internal shift register unrelated with the $\overline{\text{CLR}}$ and $\overline{\text{STB}}$ status.

Furthermore, the 4 input circuits provide a hysteresis characteristics using the schmitt trigger structure to protect the noise.

CLK	$\overline{\text{STB}}$	$\overline{\text{CLR}}$	OPERATION
X	X	L	All of latches are reset (the data in the shift register is no change). All of parallel conversion outputs are "L".
	H	H	The serial data into the DATA terminal are inputted to the shift register. In this stage, the data in the latch is not changed.
L	L	H	The data in the shift register is transferred to the latch. And the data in the latch is output from the parallel conversion output terminals.
H			
	L	H	When the clock signal is inputted into the CLK terminal in state of the $\overline{\text{STB}}="L"$ and $\overline{\text{CLR}}="H"$, the data is shifted in the shift register and latched data is also changed in accordance with the shift register.

Note 2) All voltage are relative to $V_{SS}=0V$ reference.

Note 3) Do not exceed the absolute maximum ratings, otherwise the stress may cause a permanent damage to the IC. It is also recommended that the IC be used in the range specified in the DC electrical characteristics, or the electrical stress may cause malfunctions and impact on the reliability.

Note 4) To stabilize the IC operation, place decoupling capacitor between V_{DD} and V_{SS} .

Note 5) $V_{DD}=7V, V_{SS}=0V$, less than 1 second per pin.
