

IR3829

16A Highly Integrated Single-Input Synchronous Sup*IR*Buck® Regulator

Datasheet

Rev 3.7, 03/24/2016

Power Management & Multimarket

1 Product Overview

Features

- Single 5V to 21V application
- Wide Input Voltage Range from 1.0V to 21V with external Vcc
- Output Voltage Range: 0.6V to 0.86×Vin
- Enhanced Line/Load Regulation with Feed-Forward
- Programmable Switching Frequency up to 1.2MHz
- Internal Digital Soft-Start
- Three selectable current limits
- Enable input with Voltage Monitoring Capability
- Thermally Compensated Internal Over-Current Protection with Three selectable settings
- Enhanced Pre-Bias Start-Up
- Precision Reference Voltage (0.6V+/-0.6%)
- Integrated MOSFET drivers and Bootstrap Diode
- Thermal Shut Down
- Programmable Power Good Output
- Monotonic Start-Up
- Operating temp: $-40\degree C < Tj < 125\degree C$
- Small Size: PQFN 5 mm x 6 mm
- Lead-free, Halogen-free and RoHS Compliant

Description

The IR3829 SupIRBuck® is an easy-to-use, fully integrated and highly efficient DC/DC regulator. The onboard PWM controller and MOSFETs make IR3829 a space-efficient solution, providing accurate power delivery.

IR3829 is a versatile regulator, operating with wide input and output voltage range, which offers programmable switching frequency from 300kHz to 1.2MHz, and three selectable current limits.

It features important protection functions, such as Pre-Bias startup, thermally compensated current limit, over voltage protection and thermal shutdown to give required system level security in the event of fault conditions.

Applications

5.1 Absolute Maximum Ratings

Stresses beyond those listed in **Table 5-1** may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications are not implied.

Table 5-1 Absolute Maximum Ratings

Note 1: Vcc must not exceed 7.5V for Junction Temperature between -10°C and -40°C **Note 2:** Must not exceed 8V

Table 5-2 Thermal Information

Note 3: θ_{JA} is measured with components mounted on a high effective thermal conductivity test board in free air.

5.2 Recommended Operating Conditions

Table 5-3 Recommended Operating Conditions

Note 4: Maximum SW node voltage should not exceed 25V.

Note 5: For internally biased single rail operation. When Vin drops below 7.5V, the internal LDO enters dropout mode. Please refer to LDO section and Over Current Protection for detailed application information.

Note 6: Vcc/LDO_out can be connected to an external regulated supply. If so, the Vin input should be connected to Vcc/LDO_out pin.

5.3 Electrical Characteristics

Unless otherwise specified, these specifications apply over, $7.5V <$ Vin = PVin < $21V$, $0^{\circ}C < T$, < $125^{\circ}C$. Typical values are specified at $Ta = 25^{\circ}C$.

Figure 5-7 Typical Operation Characteristics (Set 1 of 2)

Figure 5-8 Typical Operation Characteristics (Set 2 of 2)

6 Theory of Operation

The IR3829 uses a PWM voltage mode control scheme with external compensation to provide good noise immunity and maximum flexibility in selecting inductor values and capacitor types.

The switching frequency is programmable from 300 kHz to 1.2MHz and provides the capability of optimizing the design in terms of size and performance. IR3829 provides precisely regulated output voltage programmed via two external resistors from 0.6V to 0.86*Vin.

The IR3829 operates with an internal bias supply (LDO) which is connected to the Vcc/LDO_out pin. This allows operation with single supply. The IC can also be operated with an external supply from 4.5 to 7.5V, allowing an extended operating input voltage (PVin) range from 1.0V to 21V. For using the internal LDO supply, the Vin pin should be connected to PVin pin. If an external supply is used, it should be connected to Vcc/LDO_Out pin and the Vin pin should be shorted to Vcc/LDO_Out pin.

The device utilizes the on-resistance of the low side MOSFET (sync FET) for over current protection. This method enhances the converter's efficiency and reduces cost by eliminating the need for external current sense resistor. IR3829 includes two low R_{ds(on)} MOSFETs using Infineon's HEXFET technology. These are specifically designed for high efficiency applications.

6.1 Voltage Loop Compensation Design

The IR3829 uses PWM voltage mode control. The output voltage of the POL, sensed by a resistor divider, is fed into an internal Error Amplifier (E/A). The output of the E/R is then compared to an internal ramp voltage to determine the pulse width of the gate signal for the control FET. The amplitude of the ramp voltage is proportional to V_{in} so that the bandwidth of the voltage loop remains almost constant for different input voltages. This feature is called input voltage feedfoward. It allows the feedback loop design independent of the input voltage. Please refer to the feedforward section for more information.

A RC network has to be connected between the FB pin and the COMP pin to form a feedback compensator. The goal of the compensator design is to achieve a high control bandwidth with a phase margin of 45° or above. The high control bandwidth is beneficial for the loop dynamic response, which helps to reduce the number of output capacitors, the PCB size and the cost. A phase margin of 45° or higher is desired to ensure the system stability. The proprietary PWM modulator in IR3829 significantly reduces the PWM jittering, allowing the control bandwidth in the range of $1/10^{th}$ to $1/5^{th}$ of the switching frequency.

Two types of compensators, Type II (PI) and Type III (PID), are commonly used. The selection of the compensation type is dependent on the ESR of the output capacitors. Electrolytic capacitors have relatively higher ESR. If the ESR pole is located at the frequency lower than the cross-over frequency, F_{C} , the ESR pole will help to boost the phase margin. Thus a type II compensator can be used. For the output capacitors with lower ESR such as ceramic capacitors, type III compensation is often desired.

Figure 6-1 Loop Compensators

Table 6-1 lists the compensation selection for different types of output capacitors.

For more detailed design guideline of voltage loop compensation, please refer to the application note AN-1162, "Compensation Design Procedure for Buck Converter with Voltage-Mode Error-Amplifier". SupBuck design tool is also available at (**www.infineon.com**) providing the reference design based on user's design requirements.

 F_{LC} is the resonant frequency of the output LC filter. It is often referred to as double pole.

 F_{FSR} is the ESR zero of the output capacitor.

 F_O is the cross-over frequency of the control loop and F_S is the switching frequency.

$$
F_{LC} = \frac{1}{2 \times \pi \sqrt{L_o \times C_o}}
$$

$$
F_{ESR} = \frac{1}{2 \pi \times ESR \times C_o}
$$

6.2 Under-Voltage Lockout and Power On Ready

The under-voltage lockout circuit monitors the voltage of Vcc/LDO_Out pin and the Enable input. It assures that the MOSFET driver outputs remain in the off state whenever either of these two signals drop below the set thresholds. Normal operation resumes once Vcc/LDO_Out and Enable rise above their thresholds.

The POR (Power On Ready) signal is generated when all these signals reach the valid logic level (see system block diagram). The soft start sequence starts when the POR is asserted.

6.3 Enable

The Enable features another level of flexibility for startup. The Enable has precise threshold, which is internally monitored by Under-Voltage Lockout (UVLO) circuit. Therefore, the IR3829 will turn on only when the voltage at the Enable pin exceeds this threshold, typically, 1.2V.

If the input to the Enable pin is derived from the bus voltage by a suitably programmed resistive divider, it can be ensured that the IR3829 does not turn on until the bus voltage reaches the desired level (**Figure 6-2**). Only after the bus voltage reaches or exceeds this level and voltage at the Enable pin exceeds its threshold, IR3829 will be enabled. Therefore, in addition to being a logic input pin to enable the IR3829, the Enable feature, with its precise threshold, also allows the user to implement an Under-Voltage Lockout for the bus voltage (PVin). This is desirable particularly for high output voltage applications, where we might want the IR3829 to be disabled until PVin exceeds the desired output voltage level.

IR3829

Theory of Operation

Figure 6-2 Normal start-up with Enable connected to PVin through a resistor divider at 10.2V

When Enable is used as a logic input, the recommended start-up sequence for the normal operation of IR3829 is shown in **Figure 6-3**.

Figure 6-3 Normal start-up with a logic input for Enable signal

It is recommended to add a 1kΩ resistor in series with the Enable pin to limit the current flowing into the Enable pin. In addition, the Enable pin should not be left floating. A pull-down resistor in the range of several kilo ohms is recommended to connect between the Enable Pin and Gnd.

6.4 Pre-bias Startup

IR3829 is able to start up into pre-charged output, without oscillations and disturbances of the output voltage. The output starts in asynchronous fashion and keeps the synchronous MOSFET (Sync FET) off until the first gate signal for control MOSFET (Ctrl FET) is generated. **Figure 6-4** shows a typical pre-bias condition at startup.

Figure 6-4 Pre-Bias Startup

The sync FET always starts with a narrow pulse width (12.5% of a switching period) and gradually increases its duty cycle with a step of 12.5% until it reaches the steady state value. The number of these startup pulses for each step is 16 and it's internally programmed. **Figure 6-5** shows the series of 16x8 startup pulses.

Figure 6-5 Pre-bias Startup Pulses

6.5 Soft Start

IR3829 has an internal digital soft-start to control the output voltage rise and to limit the current surge at the startup. To ensure correct start-up, the soft-start sequence initiates when the Enable and Vcc rise above their UVLO thresholds and generate the Power On Ready (POR) signal. The internal soft-start (Intl_SS) signal linearly rises with the rate of 0.2mV/µs from 0V to 1.5V. **Figure 6-6** shows the waveforms during the soft-start. The normal Vout start-up time is fixed, and is equal to:

$$
T_{\text{start}} = \frac{0.75 \text{V} - 0.15 \text{V}}{0.2 \text{mV/us}} = 3.0 \text{ms}
$$

During the soft-start, the over-current protection (OCP) and over-voltage protection (OVP) are enabled to protect the device for any short circuit or over voltage condition.

Figure 6-6 Theoretical Waveforms during Soft-Start

6.6 Operating Frequency

The switching frequency can be programmed between 300 kHz – 1.2 MHz by connecting an external resistor from R_t pin to Gnd. Table 2 lists the R_t with each corresponding switching frequency.

R_t (KΩ)	F_S (kHz)
80.6	300
60.4	400
48.7	500
39.2	600
34.0	700
29.4	800
26.1	900
23.2	1000
21.0	1100
19.1	1200

Table 6-2 Switching Frequency (F^s) vs. External Resistor (R^t)

6.7 Shutdown

IR3829 can be shut down by pulling the Enable pin below its 1.0V threshold. This will put both the high side and the low side driver in a tri-state.

6.8 Over Current Protection

The over current (OC) protection is performed by sensing current through the $R_{DS(on)}$ of the Synchronous MOSFET. This method enhances the converter's efficiency, reduces cost by eliminating a current sense resistor and any layout related noise issues. The over current (OC) limit can be set to one of three possible settings by floating the ILIM pin, by pulling up the ILIM pin to VCC, or pulling down the ILIM pin to PGnd. The current limit is internally compensated according to the IC temperature. So at different ambient temperature, the over-current trip threshold remains almost constant.

Note that the over current limit is affected by the Vcc voltage. In general, a lower Vcc voltage increases the $R_{DS(on)}$ of the Synchronous MOSFET and hence results in a lower OCP limit. Please refer to the typical performance curves of the OCP current limit with different Vcc voltages.

To prevent false tripping induced by noise and transients, the current near the valley of the inductor current is sensed by the Over Current Protection circuit. More precisely, the inductor current is sampled for about 40ns on the downward inductor current slope approximately 12.5% of the switching period before the inductor current valley. When the current exceeds the OCP limit, an over current condition is detected.

When an Over Current event is detected, PGood signal is pulled low and the device enters hiccup mode. Hiccup mode is performed by latching an internal OC signal, which keeps both Control FET and Synchronous FET off for 20.48ms (typical) blanking time. OC signal clears after the completion of blanking time and the device attempts to recover to the nominal output voltage with a soft-start, as shown in **Figure 6-7**. The device will repeat hiccup mode and attempt to recover until the overload or short circuit conditions is removed.

Since the current sensing point is near the valley of the inductor current, the actual DC output current limit point will be greater than the valley point by approximately one half of peak to peak inductor ripple current. The DC current limit point can be calculated by the following equation. It should be pointed out that the OCP limits specified in the Electrical Table refer to the over current limit valley point.

$$
I_{OCP} = I_{LIMIT} + \frac{\Delta I}{2}
$$

 $I_{OCP} = DC$ current limit hiccup point I_{LIMIT} = Over Current limit (valley of inductor current) ΔI = Inductor ripple current

Figure 6-7 Timing Diagram for Current Limit Hiccup

6.9 Thermal Shutdown

Temperature sensing is provided inside IR3829. The trip threshold is typically set to 145°C. When trip threshold is exceeded, thermal shutdown turns off both MOSFETs and resets the internal soft start.

Automatic restart is initiated when the sensed temperature drops within the operating range. There is a 20° C hysteresis in the thermal shutdown threshold.

IR3829

Theory of Operation

6.10 Feed-Forward

Feed-Forward is an important feature, because it can keep the converter stable and preserve its load transient performance when Vin varies in a large range. In IR3829, Feed-Forward function is enabled when Vin pin is connected to PVin pin. In this case, the internal low dropout (LDO) regulator is used. The PWM ramp amplitude (Vramp) is proportionally changed with Vin to maintain Vin/Vramp almost constant throughout Vin variation range as shown in the timing diagram. Thus, the control loop bandwidth and phase margin can be maintained constant. Feed-forward function can also minimize impact on output voltage from fast Vin change. The maximum Vin slew rate is within 1V/us.

If an external bias voltage is used as Vcc, Vin pin should be connected to Vcc/LDO out pin instead of PVin pin. Then the Feed-Forward function is disabled. A re-calculation of loop compensation parameters is needed.

Figure 6-8 Timing diagram for Feed-Forward function

6.11 Low Dropout Regulator (LDO)

IR3829 has an integrated low dropout (LDO) regulator which can provide gate drive voltage for both drivers.

For internally biased single rail operation, Vin pin should be connected to PVin pin. If external bias voltage is used, Vin pin should be connected to Vcc/LDO_Out pin as shown in the figure.

Figure 6-9 Internal LDO or External V_{CC} Configurations

When the Vin voltage is below 7.5V, the internal LDO may enter the dropout mode. The dropout voltage increases with the switching frequency. The figure shows the LDO voltage for 600kHz and 1000kHz respectively.

Figure 6-10 LDO Voltage with Vin = 5V

6.12 Power Good Output

IR3829 continually monitors the output voltage via the sense pin (Vsns) voltage. The Vsns voltage is an input to the window comparator with upper and lower turn-off threshold of 120% and 85% of the reference voltage respectively. PGood signal is high whenever Vsns voltage is within the PGood comparator window thresholds. The

PGood is an open drain output. Hence, a pull-up resistor is needed to limit the current flowing into the PGood pin less than 5mA when the output voltage is not in regulation. A typical value used is 49.9kΩ. High state indicates that output is in regulation. **Figure 6-11** shows the timing diagram of the PGood signal. Vsns signal is also used by OVP comparator for detecting output over voltage condition.

Figure 6-11 Vsns vs. PGood Relationship Timing Diagram

6.13 Over-Voltage Protection (OVP)

OVP is achieved by comparing Vsns voltage to an OVP threshold voltage, 1.2 x Vref. When Vsns exceeds the OVP threshold, an over voltage trip signal asserts after 2us typical delay. Then the control FET is latched off immediately, PGood flags low. The sync FET remains on to discharge the output capacitor. When the Vsns voltage drops below the threshold, the sync FET turns off to prevent the complete depletion of the output capacitor. The control FET remains latched off until either Vcc or Enable signal is re-cycled.

OVP comparator becomes active when the enable signal exceeds the start threshold. Vsns voltage is set by the voltage divider connected to the output and it can be programmed externally.

Figure 6-12 OVP Timing Diagram

6.14 Minimum On Time Considerations

The minimum ON time is the shortest amount of time for Control FET to be reliably turned on. This is a very critical parameter for low duty cycle, high frequency applications. Conventional approach limits the pulse width to prevent noise, jitter and pulse skipping. This results in lower closed loop bandwidth.

Infineon has developed a proprietary scheme to improve and enhance minimum pulse width that utilizes the benefits of voltage mode control scheme with higher switching frequency, wider conversion ratio and higher closed loop bandwidth, the latter results in reduction of output capacitors. Any design or application using IR3829 must ensure operation with a pulse width that is higher than this minimum on-time. This is necessary for the circuit to operate without jitter and pulse-skipping, which can cause high inductor current ripple and high output voltage ripple.

$$
t_{on} = \frac{D}{F_s} = \frac{V_{out}}{V_{in} \times F_s}
$$

In any application that uses IR3829, the following conditions must be satisfied:

$$
t_{on(\min)} \leq t_{on}
$$

$$
t_{on(\min)} \leq \frac{V_{out}}{V_{in} \times F_s}
$$

$$
V_{in} \times F_s \leq \frac{V_{out}}{t_{on(\min)}}
$$

The minimum output voltage is limited by the reference voltage and hence Vout(min) = 0.6 V. Therefore, for Vout(min) = $0.6 V$,

$$
V_{in} \times F_s \le \frac{V_{out}}{t_{on(min)}} = \frac{0.6V}{60 \, ns} = 10 \, \text{V/} \, \mu\text{s}
$$

Therefore, at the maximum recommended input voltage of 21V and minimum output voltage, the converter should be designed at a switching frequency that does not exceed 476 kHz. Conversely, for operation at the maximum recommended operating frequency (1.2MHz) and minimum output voltage (0.6V), the input voltage (PVin) should not exceed 8.3V. Else pulse skipping will happen.

6.15 Maximum Duty Ratio

IR3829 is designed to have a maximum duty ratio of 0.86 for most applications. In addition, there are two other factors to limit the maximum duty ratio. One is the minimum off-time, which is more dominant at high switching frequency. The other factor is the maximum output voltage of the error amplifier. Due to the built-in input voltage feedforward, the ramp voltage of the internal PWM modulator increases with Vin. However the output of the error amplifier is clamped at the maximum voltage as specified in the electrical table, which can result in a max duty ratio smaller than 0.86 at high Vin. The figure shows a plot of the maximum duty ratio vs. the switching frequency with built in input voltage feedforward.

IR3829

Theory of Operation

Figure 6-13 Maximum Duty Cycle vs. Switching Frequency with Vin Feedforward

7 Applications Design Example

The following key parameters shall be used as an example for typical IR3829 applications. The application circuit is shown in **Section 7.9**.

- $PV_{in} = V_{in} = 12V$ (±10%)
- $V_{\Omega} = 1.0V$
- \cdot I_O = 16A
- Peak-to-Peak Ripple Voltage = 1% of V_{Ω}
- Δ Vo = \pm 4% of V_o (for 30% Load Transient)
- $F_s = 600$ kHz

7.1 Enabling The IR3829

As explained earlier, the precise threshold of the Enable lends itself well to implementation of a UVLO for the Bus Voltage shown by the resistor divider network.

$$
V_{in(min)} \times \frac{R_2}{R_1 + R_2} = V_{EN} = 1.2 \text{V}
$$

$$
R_2 = R_1 \times \frac{V_{EN}}{V_{in(min)} - V_{EN}}
$$

For V_{in} (min)= 9.2V, R1= 49.9kΩ and R2 = 7.5kΩ is a good choice.

7.2 Programming the Frequency

 $\mathsf{For} \; \mathsf{F}_{\mathsf{S}}$ = 600kHz, select R_{t} = 39.2kΩ, using **Table 6-2.**

7.3 Output Voltage Programming

Output voltage is programmed by reference voltage and external voltage divider. The Fb pin is the inverting input of the error amplifier, which is internally referenced to 0.6V. The divider ratio is set to provide 0.6V at the Fb pin when the output is at its desired value. The output voltage and the external resistor dividers connected to the output are defined by using the equations:

$$
V_o = V_{ref} \times (1 + \frac{R_{F1}}{R_{F2}})
$$

$$
R_{F2} = R_{F1} \times \left(\frac{V_{ref}}{V_o - V_{ref}}\right)
$$

For the calculated values of R_{F1} and R_{F2} , see feedback compensation section.

Figure 7-2 Output Voltage Programming for Typical Applications of IR3829

7.4 Bootstrap Capacitor Selection

To drive the Control FET, it is necessary to supply a gate voltage at least 4V greater than the voltage at the SW pin, which is connected to the source of the Control FET. This is achieved by using a bootstrap configuration, which comprises the internal bootstrap diode and an external bootstrap capacitor (C1).

When the sync FET is turned on, the capacitor node connected to SW is pulled down to ground. The capacitor charges towards Vcc through the internal bootstrap diode, which has a forward voltage drop V_D. The voltage Vc across the bootstrap capacitor C1 is approximately given as:

$$
V_C = V_{CC} - V_D
$$

When the control FET turns on in the next cycle, the capacitor node connected to SW rises to the bus voltage Vin. However, if the value of C1 is appropriately chosen, the voltage Vc across C1 remains approximately unchanged and the voltage at the Boot pin becomes:

$$
V_{\text{BOOT}} = V_{\text{in}} + V_{\text{CC}} - V_{\text{D}}
$$

Figure 7-3 Bootstrap Circuit to Generate Vc Voltage.

7.5 Input Capacitor Selection

The ripple current generated during the on time of the control FET should be provided by the input capacitor. The RMS value of this ripple is expressed by:

$$
I_{RMS} = I_o \times \sqrt{D \times (1 - D)}
$$

$$
D = \frac{V_o}{V_{in}}
$$

Where:

D is the Duty Cycle

 I_{RMS} is the RMS value of the input capacitor current. Io is the output current.

For I_{Ω} = 16A and D = 0.0833, the I_{RMS} = 4.42A.

Ceramic capacitors are recommended due to their peak current capabilities. They also feature low ESR and ESL at higher frequency which enables better efficiency. For this application, it is advisable to have 5x10μF, 25V ceramic capacitors, C3216X5R1E106M from TDK. In addition to these, although not mandatory, a 1x330μF, 25V SMD capacitor EEV-FK1E331P from Panasonic may also be used as a bulk capacitor and is recommended if the input power supply is not located close to the converter.

7.6 Inductor Selection

The inductor is selected based on output power, operating frequency and efficiency requirements. A low inductor value causes large ripple current, resulting in the smaller size, faster response to a load transient but poor efficiency and high output noise. Generally, the selection of the inductor value can be reduced to the desired maximum ripple current in the inductor (ΔiL). The optimum point is usually found between 20% and 50% ripple of the output current.

For the buck converter, the inductor value for the desired operating ripple current can be determined using the following relations:

$$
V_{in\max} - V_o = L \times \frac{\Delta i_L}{\Delta t} \qquad \Delta t = \frac{D}{F_s}
$$

$$
L = (V_{in\max} - V_o) \times \frac{V_o}{V_{in\max} \times \Delta i_L \times F_s}
$$

Where:

 V_{inmax} = Maximum input voltage

 V_{Ω} = Output Voltage

 Δi_1 = Inductor Peak-to-Peak Ripple Current

 F_s = Switching Frequency

Δt = On time for Control FET

 $D = Duty$ Cycle

If Δi_L ≈ 25%*Io, then the output inductor is calculated to be 0.38μH. Select L=0.4μH, FP1107R1-R40-R, from Coiltronics which provides an inductor suitable for this application.

7.7 Output Capacitor Selection

The voltage ripple and transient requirements determine the output capacitors type and values. The criterion is normally based on the value of the Effective Series Resistance (ESR). However the actual capacitance value and

the Equivalent Series Inductance (ESL) are other contributing components. These components can be described as:

> (c) – 8 $\sum_{o(ESL)} = \left(\frac{v_{in} - v_{o}}{I}\right) \times ESL$ $\Delta V_{o(ESR)} = \Delta I_L \times ESR$ $\Delta V_o = \Delta V_{o(ESR)} + \Delta V_{o(ESL)} + \Delta V_{o(C)}$ $\sum s$ $\frac{G}{\phi(C)} = \frac{G}{8 \times C_o \times F}$ $V_{\rho(C)} = \frac{\Delta I}{2}$ *L* $\Delta V_{o(ESL)} = \left(\frac{V_{in} - V_o}{I}\right) \times$ $\times C_{\alpha} \times$ $\Delta V_{o(C)} = \frac{\Delta}{2}$

Where:

 $\Delta V_{\rm O}$ = Output Voltage Ripple

 ΔI_L = Inductor Ripple Current

Since the output capacitor has a major role in the overall performance of the converter and determines the result of transient response, selection of the capacitor is critical. The IR3829 can perform well with all types of capacitors.

As a rule, the capacitor must have low enough ESR to meet output ripple and load transient requirements.

The goal for this design is to meet the voltage ripple requirement in the smallest possible capacitor size. Therefore it is advisable to select ceramic capacitors due to their low ESR and ESL and small size. In this case a good choice is six 47uF ceramic capacitors, C2012X5R0J476M from TDK. The ESR of this type of capacitor is around 3mΩ each. The de-rated capacitance value with 1.0VDC bias and 10mVAC voltage is around 29uF each.

It is also recommended to use a 0.1μ F ceramic capacitor at the output for high frequency filtering.

7.8 Feedback Compensation

For this design, the resonant frequency of the output LC filter, F_{LC} , is:

$$
F_{LC} = \frac{1}{2 \times \pi \sqrt{L_o \times C_o}}
$$

=
$$
\frac{1}{2 \times \pi \sqrt{0.4 \times 10^{-6} \times 6 \times 29 \times 10^{-6}}}
$$

= 19.1kHz

The equivalent ESR zero of the output capacitors, F_{ESR} , is:

$$
F_{ESR} = \frac{1}{2\pi \times ESR \times C_o}
$$

=
$$
\frac{1}{2\pi \times 3 \times 10^{-3} \times 29 \times 10^{-6}}
$$

= 1.8MHz

Designing crossover frequency around 1/7th of switching frequency gives $F_{\text{o}} = 80$ kHz.

According to **Table 6-1**, Type III B compensation is selected for $F_{LC} < F_{O} < F_{S/2} < F_{FSR}$. Type III compensator is shown in **Figure 7-4** for easy reference.

Figure 7-4 Type III compensation and its Asymptotic Gain Plot

As shown in **Figure 7-4**, Type III compensator contains two zeros and three poles. The zeros are:

$$
F_{Z1} = \frac{1}{2\pi \times R_{C1} \times C_{C1}}
$$

$$
F_{Z2} = \frac{1}{2\pi \times C_{F3} \times (R_{F3} + R_{F1})}
$$

The poles are:

$$
F_{p_1} = 0
$$

\n
$$
F_{p_2} = \frac{1}{2\pi \times R_{F3} \times C_{F3}}
$$

\n
$$
F_{p_3} = \frac{1}{2\pi \times R_{C1} \times C_{C2}}
$$

To archive the sufficient phase boost near the cross-over frequency, it is desired to place one zero and one pole as follows:

$$
F_{Z2} = F_0 \sqrt{\frac{1 - \sin \theta}{1 + \sin \theta}} = 80 \times 10^3 \sqrt{\frac{1 - \sin 70}{1 + \sin 70}} = 14.1 \text{kHz}
$$

$$
F_{P2} = F_0 \sqrt{\frac{1 + \sin \theta}{1 - \sin \theta}} = 80 \times 10^3 \sqrt{\frac{1 + \sin 70}{1 - \sin 70}} = 454.0 \text{kHz}
$$

To compensate the phase lag of the pole at the origin and to provide extra phase boost, the other zero could be placed at one half of the first zero, i.e. F_{Z1} = 7.05 kHz. The third pole is usually placed at one half of the switching frequency to damp the switching noise. i.e. $F_{p3} = 300$ kHz.

Please note that the zeros and poles locations do not necessarily follow the general design guides above and could vary with the design preference. The selected compensation parameters are: R_{F1}=4.02kΩ, R_{F2}=6.04kΩ, $R_{F3}=100\Omega$, C_{F3}=3300pF, R_{C1}=1.5kΩ, C_{C1}=10nF, C_{C2}=220pF. Finally, select the Vsns resistors (R7 / R8 in **Section 7.9**) to the same ratio of R_{F1} / R_{F2} to ensure the proper OVP and Pgood operations.

8 Layout Considerations

The layout is very important when designing high frequency switching converters. Layout will affect noise pickup and can cause a good design to perform with less than expected results.

Make the connections for the power components on the top layer with wide, copper filled areas or polygons. In general, it is desirable to make proper use of power planes and polygons for power distribution and heat dissipation.

The inductor, output capacitors and the IR3829 should be as close to each other as possible. This helps to reduce the EMI radiated by the power traces due to the high switching currents through them. Place the input capacitor directly at the PVin pin of IR3829. The critical bypass components such as capacitors for Vin, Vcc and Vref should be close to their respective pins. The feedback part of the system should be kept away from the inductor and other noise sources. It is important to place the feedback components including feedback resistors and compensation components close to Fb and Comp pins.

In a multilayer PCB use one layer as a power ground plane and have a control circuit ground (analog ground), to which all signals are referenced. The goal is to localize the high current path to a separate loop that does not interfere with the more sensitive analog control function. These two grounds must be connected together on the PC board layout at a single point. It is recommended to place all the compensation parts over the analog ground plane on top layer.

The Power QFN is a thermally enhanced package. Based on thermal performance it is recommended to use at least a 4-layers PCB. To effectively remove heat from the device the exposed pad should be connected to the ground plane using vias. The figures illustrate the implementation of the layout guidelines outlined above, on the IRDC3829 4-layer demo board.

8.1 PCB Metal and Component Placement

Evaluations have shown that the best overall performance is achieved using the substrate/PCB layout as shown in following Figures. PQFN devices should be placed to an accuracy of 0.050mm on both X and Y axes. Selfcentering behavior is highly dependent on solders and processes and experiments should be run to confirm the limits of self-centering on specific processes.

IR3829

Layout Considerations

Figure 8-5 PCB metal pad sizing and spacing (all dimensions in mm)

8.2 Solder Resist

- It is recommended that the larger Power or Land Area pads are Solder Mask Defined (SMD.)
	- This allows the underlying Copper traces to be as large as possible, which helps in terms of current carrying capability and device cooling capability.
- When using SMD pads, the underlying copper traces should be at least 0.05mm larger (on each edge) than the Solder Mask window, in order to accommodate any layer to layer misalignment. (i.e. 0.1mm in X & Y.)
- However, for the smaller signal type leads around the edge of the device, it is recommended that these are Non Solder Mask Defined or Copper Defined.
- When using NSMD pads, the Solder Resist Window should be larger than the Copper Pad by at least 0.025mm on each edge, (i.e. 0.05mm in X&Y,) in order to accommodate any layer to layer misalignment.
- Ensure that the solder resist in-between the smaller signal lead areas are at least 0.15mm wide, due to the high x/y aspect ratio of the solder mask strip.

Figure 8-6 Solder Resist

8.3 Stencil Design

- Stencils for PQFN can be used with thicknesses of 0.100-0.250mm (0.004-0.010"). Stencils thinner than 0.100mm are unsuitable because they deposit insufficient solder paste to make good solder joints with the ground pad; high reductions sometimes create similar problems. Stencils in the range of 0.125mm-0.200mm (0.005-0.008"), with suitable reductions, give the best results.
- Evaluations have shown that the best overall performance is achieved using the stencil design shown in following Figure. This design is for a stencil thickness of 0.127mm (0.005"). The reduction should be adjusted for stencils of other thicknesses.
