Am79101

WORLD-CHIP Autodial FSK Modem

DISTINCTIVE CHARACTERISTICS

- Bell 103, 113, 108 and CCITT V.21 compatible at 300 bps full-duplex
 - Call-Progress Tone Detection
 - Answer-Tone Detection
- Bell 202 and CCITT V.23 compatible at 1200-bps half-duplex with up to 150-bps back-channel (CCITT V.23 modes with optional soft carrier turn-off feature)
- Single-chip digital signal processor
- Autodial support
 - Dual-Tone Multi-Frequency (DTMF) Tone Generation
- Integral 4- to 2-wire hybrid
- Public Switched Telephone Network (PSTN) response times
- Serial RS-232C/CCITT V.24-type handshake interface and protocol

GENERAL DESCRIPTION

The Am79101 WORLD-CHIP® is a single-chip asynchronous Frequency Shift Keying (FSK) modem that is compatible with the applicable Bell and CCITT-recommended standards for 103/113/108, 202, V.21 and V.23-type modems. All modulation, demodulation, filtering, analog-to-digital and digital-to-analog functions are provided on-chip.

Using the features described here, an intelligent Autodial, Autoanswer FSK modem may be implemented with only an Am79101 single-chip under the control of a host microprocessor and a Data Access Arrangement (DAA) circuit.

The modem operates in a serial asynchronous mode; the serial interface supports the RS-232C/CCITT V.24-type handshake signals at TTL levels.

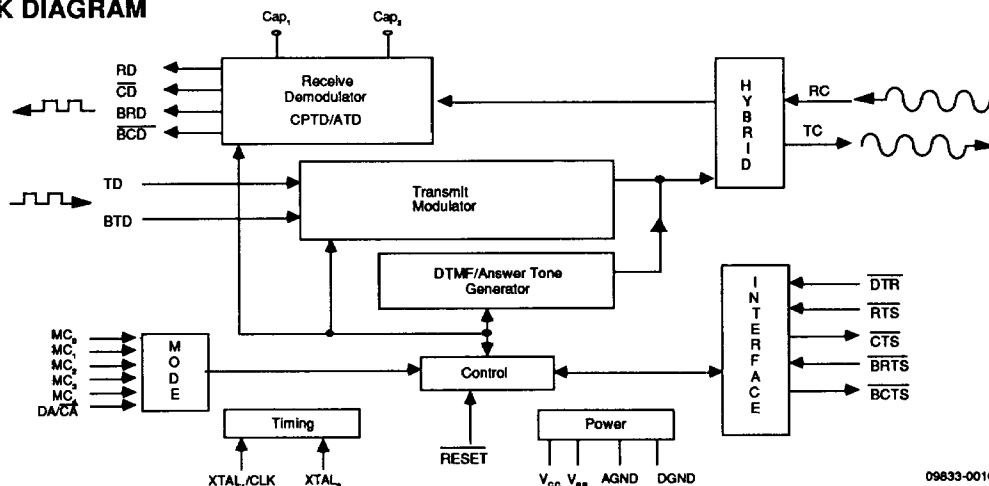

The modem analog interface provides an internal hybrid for the 4- to 2-wire conversion. Auxiliary functions performed within the Am79101 include:

- Autodial support with DTMF generation and Call Progress Tone Detection
- Answer Tone Detection (Bell and CCITT)
- Autoanswer support
- Analog loopback support

The Am79101 is housed in a 28-pin plastic leaded chip carrier as well as 28-pin plastic and ceramic dual-in-line packages.

Connection to the telephone network may be via a DAA or an acoustic coupler. All digital I/O signals are TTL-compatible, except the external clock and RESET signals, and the circuit operates from ± 5 V.

ORDERING INFORMATION

Standard Products

AMD standard products are available in several packages and operating ranges. The order number (Valid Combination) is formed by a combination of:

- a. Device Number
- b. Speed Option (If applicable)
- c. Package Type
- d. Temperature Range
- e. Optional Processing

Valid Combinations

Valid Combinations	
AM79101	DC, DCB, DI, DIB, PC, DE, DEB, JC

Valid Combinations list configurations planned to be supported in volume for this device. Consult the local AMD sales office to confirm availability of specific valid combinations, to check on newly released valid combinations, and to obtain additional data on AMD's standard military grade products.

PIN DESCRIPTION

All digital inputs and outputs are TTL-compatible unless otherwise noted.

Setup Controls

$\overline{DA/\overline{CA}}$

Data/Call (Input)

This input selects the Data Mode ($\overline{DA/\overline{CA}} = \text{High}$) or the Call Mode ($\overline{DA/\overline{CA}} = \text{Low}$). In the Data Mode, the Am79101 operates as a modem, using other setup and handshake inputs. Data Mode is the initial condition by default.

To enter the Call Mode, $\overline{DA/\overline{CA}}$ is brought to a Low while \overline{DTR} is High and MC pins are set to a valid mode, that is, not a reserved mode. Once in the Call Mode, \overline{DTR} is set Low. MC inputs and \overline{RTS} will determine the generation of either DTMF or answer tones, and the detection of call progress tones or answer tones. To re-enter the Data Mode, $\overline{DA/\overline{CA}}$ is returned to a High during a valid modem mode.

\overline{DTR}

Data Terminal Ready (Input)

A Low level on this input indicates the data terminal is ready to send and/or receive data via the modem. This signal is gated with all other TTL inputs and outputs so that a Low level enables these signals as well as the internal control logic. A High disables all TTL I/O pins and the internal logic.

When \overline{DTR} is High, the modem handshake state machine is reset to initial conditions. This is the only way to reset the state machine, and must be done after power-up. The state machine does not automatically power up to a known state. If \overline{DTR} is permanently enabled (Low), the state machine will simply run from wherever it powers up. This can result in abnormal behavior such as an unusually short \overline{RTS} - \overline{CTS} delay due to lack of \overline{DTR} initialization.

To change the modem mode when powered-up, use the following sequence (see Figure 16):

- Set \overline{DTR} High
- Change MC inputs to desired configuration
- Wait at least 100 μs
- Set \overline{DTR} Low

The MC inputs perform some hardware functions and are also sampled periodically by the state machine. If the MC inputs are changed without re-initialization using \overline{DTR} , the state machine will not completely change to the new mode. In the Call Mode, \overline{DTR} does not have to be changed when going from one DTMF digit to another.

$\overline{MC_0}$ – $\overline{MC_4}$

Mode Controls (Inputs)

In the Data Mode, the MC inputs specify one of the 25 available modem configurations as listed in Table 1a. Included are Bell 103/202, CCITT V.21/V.23 with various options such as equalizer, 150-bps back-channel, soft turn-off and loopback.

The loopback modes set the signal processing frequency band of the receiver to that of the transmitter. The user must connect TC to RC for analog loopback, and RD to TD for digital loopback as shown in Figure 1.

In the Call Mode, the MC inputs select generation of DTMF or answer tones, or detection of call progress tones or answer tones, as listed in Table 1b.

None of the reserved modes should be used.

Transmitter I/O

\overline{BCTS}

Back Clear To Send (Output)

This line is equivalent to \overline{CTS} for the main channel, except that it applies only to the back-channel. \overline{BCTS} is meaningful only when a V.23 mode or 202 150-bps (or 75-bps) back-channel mode is selected by $\overline{MC_0}$ – $\overline{MC_4}$. This signal is not used in the 202 5-bps back-channel mode.

\overline{BRTS}

Back Request To Send (Input)

Since the 1200-bps modem configurations, Bell 202, and CCITT V.23 permit only half-duplex operation over 2-wire lines, a low baud rate back-channel is provided for simultaneous transmission in the reverse direction. \overline{BRTS} is directly equivalent to main channel \overline{RTS} , except that it applies only to the back-channel. Note that since the modem contains a single transmitter, \overline{RTS} and \overline{BRTS} should not be asserted simultaneously. \overline{BRTS} is meaningful only when a 202 or V.23 mode is selected by $\overline{MC_0}$ – $\overline{MC_4}$. In all other modes, it is ignored.

For the V.23 modes and the 202 150-bps (or 75-bps) back-channel mode, the frequency appearing at TC is determined by a Mark or Space at \overline{BTD} . For the 202 5-bps back-channel mode, a frequency of 387 Hz appears at TC when \overline{BRTS} is Low and \overline{BTD} is High. No energy (0.0 V) appears at TC when \overline{BRTS} is High. \overline{BTD} should be held High in this mode. \overline{BRTS} then, is equivalent to the transmitted data. \overline{BRTS} is the Secondary Request-to-Send for 202 S/T modems, or the Supervisory Transmitted Data for 202 C/D modems.

BTD

Back Transmitted Data (Input)

This line is equivalent to TD for the main channel, except that it applies only to the back-channel. BTD is meaningful only when a 202 or V.23 mode is selected by MC_0 – MC_4 . For 202 5-bps back-channel transmission of On/Off keying, BTD should be set High.

CTS

Clear To Send (Output)

This output goes Low at the end of a delay (t_{RCON}) initiated when \overline{RTS} goes Low. Actual data to be transmitted should not be presented to TD until a Low is indicated on \overline{CTS} . This gives the receiving modem (on the other end of the phone line) enough time to recognize a valid carrier signal before data is transmitted. Normally the user should force TD High whenever \overline{CTS} is High so a Mark will be sent during the t_{RCON} time. \overline{CTS} goes High at the end of a delay initiated when \overline{RTS} goes High (t_{RCOFF}). \overline{CTS} will never be Low when \overline{DTR} is High.

RTS

Request To Send (Input)

A Low on this input instructs the modem to enter transmit mode. This input must remain Low for the duration of data transmission. This signal has no effect if \overline{DTR} is High (disabled). A High level on this input turns off the transmitter.

In the Call Mode, \overline{RTS} also controls the transmitter. When \overline{RTS} is Low, the tone specified by the MC pins will be transmitted. A High level will turn off the tone. During Answer Tone Detection and Call Progress Tone Detection, \overline{RTS} should be High.

TC

Transmitted Carrier (Output, Non-TTL-Compatible)

This analog output is the modulated carrier to be sent over the phone line. Its frequency changes according to the data at TD or BTD.

TD

Transmitted Data (Input)

Data bits to be transmitted are presented to this input serially; High (Mark) corresponds to logical "1" and Low (Space) corresponds to logical "0." This input determines which frequency is to appear at any instant at TC (see Table 2). No signal appears at TC unless \overline{DTR} is Low and \overline{RTS} is Low.

Receiver I/O

\overline{BCD}

Back Carrier Detect (Output)

This line is equivalent to \overline{CD} for the main channel, except that it applies only to the back-channel. \overline{BCD} is meaningful only when a 202 or V.23 mode is selected by MC_0 – MC_4 . For the V.23 or 202 150-bps (or 75-bps) back-channel modes, \overline{BCD} changes to Low when either the Mark or Space frequency appears with sufficient level at RC.

For the 202 5-bps back-channel mode, \overline{BCD} changes to Low in response to a 387-Hz tone of sufficient level at RC. In this case, \overline{BCD} is equivalent to the signal, Secondary Received Line Signal Detector for 202 S/T modems, or Supervisory Received Data for 202 C/D modems.

BRD

Back Received Data (Output)

This line is equivalent to RD for the main channel, except that it applies only to the back-channel. BRD is meaningful only for the V.23 or the 202 back-channel modes. Under the following conditions this output is clamped High:

- V.21/103 modes
- \overline{BCD} High
- \overline{DTR} High
- \overline{BRTS} Low and \overline{RTS} High in V.23 or 202 150-bps modes only
- During Autoanswer sequence

\overline{CD}

Carrier Detect (Output)

A Low on this output indicates that a valid carrier signal is present at the receiver and has been present for at least the time t_{CDON} . A High on this output signifies that no valid carrier is being received and has not been received for at least the time t_{CDOFF} . In the Data Mode, Carrier Detect looks for energy in the receive bandwidth. A carrier is considered valid when the signal level at RC is above a threshold limit V_{CDON} , and absent when the level is below V_{CDOFF} .

In the Call Mode, a \overline{CD} Low output indicates that a valid answer tone or call progress tone has been detected above the limit V_{CDON} . A \overline{CD} High output indicates there is no energy above the V_{CDOFF} .

RC

Received Carrier (Input, Non-TTL-Compatible)

This input is the analog signal received from the phone line. The modem extracts the information contained in this modulated carrier and converts it into a serial data stream at RD or BRD.

RD

Received Data (Output)

Data bits demodulated from RC are available serially at this output; High (Mark) indicates logic "1" and Low (Space) indicates logic "0." Under the following conditions, this output is clamped High because the data may be invalid:

- When \overline{CD} is High
- During the internal squelch delay at half-duplex line turn-around (202 and V.23 modes only)
- During soft carrier turn-off at half-duplex line turn-around (202 and V.23 soft turn-off modes only)
- When \overline{DTR} is High
- When \overline{RTS} is Low and \overline{BRTS} is High in 202 and V.23 modes only
- During Autoanswer sequence

Miscellaneous

AGND

Analog Ground

CAP₁, CAP₂ (Non-TTL-Compatible)

These two pins are connection points for the external series capacitor-resistor required for proper operation of the on-chip analog-to-digital converter.

Recommended values are: C = 2000 pF $\pm 10\%$
R = 910 $\Omega \pm 10\%$

DGND

Digital Ground

\overline{RESET}

(Non-TTL-Compatible)

This input signal is for a reset circuit which operates in either of two modes (refer to Figures 15a and 15b). The Am79101 should be reset upon initial application of power.

V_{BB} -5 V Power Supply

V_{CC} +5 V Power Supply

XTAL₁, XTAL₂ (Non-TTL-Compatible)

Master timing of the modem is provided by either a crystal connected to these two pins or an external clock inserted into XTAL₁. The value of the crystal or the external clock frequency must be 2.4576 MHz $\pm 0.1\%$.

Figure 2. Transmitter Block Diagram

FUNCTIONAL DESCRIPTION

The modem consists of three main sections shown in the Am79101 block diagram—Transmitter, Receiver, and Interface Control.

Transmitter (Modulator)

In the Data Mode, the transmitter, shown in Figure 2, receives binary digital data from a source such as a UART and converts the data to an analog signal using Frequency Shift Keying (FSK) modulation. This analog signal is applied to the phone line through a DAA or an acoustic coupler. FSK is a modulation technique which encodes one bit per baud. A logic "1" applied to the Transmitted Data (TD) input causes a sine wave at a given frequency to appear at the analog Transmitted

Carrier (TC) output. A logic "0" applied to TD causes a sine wave of a different frequency to appear at TC. As the data at TD switches between logic "1" and "0," TC switches between the two frequencies. In the Am79101, this switching between frequencies is phase continuous. The frequencies themselves are digitally synthesized sine functions. The frequencies for each modem configuration available in the Am79101 are listed in Table 2.

The process of switching between two frequencies (as in FSK) generates energy at many more frequencies than the two used in the modulation. All the transmitted information can be recovered from a frequency band B Hz wide, where B is the bit rate or maximum rate of

Table 2. Frequency Parameters

Modem Mode	Baud Rate (bps)	Duplex	Transmit Frequency		Receive Frequency	
			Space (Hz)	Mark (Hz)	Space (Hz)	Mark (Hz)
Bell 103 Originate	300	Full	1070	1270	2025	2225

* (BRTS Low) and (BTD High): 387 Hz at TC.

** 387 Hz at RC: BCD Low.

* (BRTS High) or (BTD Low): 0 V at TC.

** No 387 Hz at RC: BCD High.

Figure 3. Receiver Block Diagram

change of the digital data at TD. This band is centered about a frequency, f_c ,

$$\text{where } f_c = (f_1 + f_2)/2,$$

f_1 = lower of two FSK frequencies,

and

f_2 = higher of two FSK frequencies.

In addition to this primary information band, there are side bands containing redundant information. It is desirable to attenuate these bands for two reasons:

- The phone companies have specifications on the amount of energy allowed in certain frequency bands on the line.
- If two independent information channels are present simultaneously on the line, for example, 300-bps full-duplex or 1200-bps half-duplex with back-channel, the redundant transmitter components may fall in the frequency band of the local receiver channel and interfere with detection. In the Am79101 these redundant and undesirable components are attenuated by digital bandpass filters.

Following the digital bandpass filters, the filtered FSK signal is converted to an analog signal by an on-chip Digital-to-Analog Converter (DAC) operating at a high sampling rate. This analog FSK signal is made smooth by a simple on-chip analog low-pass filter.

In the Call Mode, the sine synthesizer generates the DTMF or answer tones as specified by the MC inputs. These tones are then processed like the FSK signal and eventually appear at TC. Table 4 shows the DTMF tone combinations.

Receiver (Demodulator)

A simplified block diagram of the Am79101 FSK receiver is shown in Figure 3. Data transmitted from a remote-site modem over the phone line is a FSK-modulated analog carrier. This carrier is applied to the RC pin via a DAA or an acoustic coupler. The first stage of the demodulator is a simple on-chip analog low-pass anti-alias filter. The output of this is converted into digital form and filtered by digital bandpass filters to improve the signal-to-noise ratio and reject other independent channel frequencies associated with the phone line in the case of full-duplex configuration. In the Data Mode, the bandpass-filtered output is digitally demodulated to recover the binary data to appear at the RD pin. A \overline{CD} is also digitally extracted from the received line carrier to indicate valid data.

In the Call Mode, the MC inputs select the proper digital bandpass filters to detect answer tones or call progress tones at RC. Presence of a valid tone will be indicated by \overline{CD} .

The on-chip hybrid provides the analog interface that communicates TC and RC directly over two wires to and from the telephone line via a DAA.

Interface Control

This section controls the handshaking between the modem and the local terminal. It consists primarily of delay-generation counters, two state machines for controlling transmission and reception, and mode-control/decode logic. Proper transmit frequencies and transmit/receive filters are selected according to the specified modem type or function in the Data or Call Mode. Inputs to and outputs from this section are as follows:

$\overline{\text{DATA/CALL}}$

$\text{MC}_0\text{--MC}_4$

$\overline{\text{DATA TERMINAL READY}}$

$\overline{\text{REQUEST TO SEND}}$ (Main and Back)

$\overline{\text{CLEAR TO SEND}}$ (Main and Back)

$\overline{\text{CARRIER DETECT}}$ (Main and Back)

$\overline{\text{RESET}}$

Internal logic clamps the handshake signals to different levels under certain conditions, e.g., initial conditions. When Bell 103/113 and V.21 modem configurations are selected, the back-channel signals are nonfunctional.

Figures 8a through 9 depict the sequencing of the two state machines. State Machine 1 implements main or back-channel transmission. State Machine 2 implements reception on main or back-channel. Table 5 lists the timing parameters, and Figures 10 through 13 show the handshake timing diagrams for the various modem modes.

The state machine powers-on to the state labeled INITIAL CONDITIONS. Handshake signals are set to or assumed to be the levels listed in Table 2. The machine then waits for Data Terminal Ready ($\overline{\text{DTR}}$) to go Low. Whenever $\overline{\text{DTR}}$ is changed from Low to High, each state

machine and external signals return to the initial conditions within 25 μs . After $\overline{\text{DTR}}$ is set Low, the Am79101 becomes operational as a modem and the state machines proceed as depicted in the flow charts.

The definitions of the terms full-duplex and half-duplex used in these flow charts are depicted in Figures 4 and 5. Full-duplex applies to all 103/113 and V.21 modes. Half-duplex applies to 202 and V.23, both main and back-channels.

Full-Duplex—Data can be transmitted and received simultaneously at 300 bps. Two independent 300-Hz channels are frequency multiplexed into the 3000-Hz bandwidth of the phone line. The Am79101 configurations for the Bell 103/113 and CCITT V.21 can be operated full-duplex.

Half-Duplex—In half-duplex with back-channel, the Am79101 may transmit at 1200/600 bps and receive at 5/75/150 bps. Alternately, it may transmit at 5/75/150 bps and receive at 1200/600 bps. Examples are Bell 202 and CCITT V.23.

Table 3. Initial Conditions

$\overline{\text{Data/Call}}$ ($\overline{\text{DA/C\AA}}$)	High (Data)
Data Terminal Ready ($\overline{\text{DTR}}$)	High
Request-to-Send (RTS)	High
Clear-to-Send ($\overline{\text{CTS}}$)	High
Transmitted Data (TD)	Ignored
Back-channel Request-to-Send ($\overline{\text{BRTS}}$)	High
Back-channel Clear-to-Send ($\overline{\text{BCTS}}$)	High
Back-channel Transmitted Data (BTD)	Ignored
Carrier Detect ($\overline{\text{CD}}$)	High
Received Data (RD)	High
Back-channel Carrier Detect ($\overline{\text{BCD}}$)	High
Back-channel Received Data (BRD)	High

Figure 5. Half-Duplex Channel Assignments

CALL ESTABLISHMENT

The Am79101 supports Autodial and Autoanswer with the following features:

- Call-Progress Tone Detection (CPTD)
- Dual-Tone Multi-Frequency (DTMF) Tone Generation
- Answer-Tone Detection (ATD)
- Answer-Tone Generation (ATG)

First, the Mode Control (MC_0 - MC_n) pins are used to set up the modem mode. Next, the Call Mode is entered by setting DA/\overline{CA} = Low (see pin description). \overline{DTR} is then set Low once at the beginning of the Autodial or Autoanswer sequence. \overline{RTS} remains High except when tones are required to be transmitted. Now the MC pins can be used to select the above Autodial/Autoanswer features, as defined in Table 1b.

Autodial begins by using the CPTD function to detect the proper dial tone from the central office. The DTMF digit to be dialed is then input to the MC pins and the transmitter generates the corresponding DTMF tones at the TC pin. After the last digit is sent, CPTD is used again to detect the ringback signal. Following the detection of ringback, the ATD feature can be used to detect the answer tone from the called modem. Following detection of the correct answer tone, data transfer can now begin. Figures 6a and 6b show the Autodial flowchart and timings.

As a called modem, the Am79101 will be placed in the Call Mode by the external microprocessor which receives a ring indication signal from the DAA. Autoanswer begins by using ATG. Figures 7a and 7b show the Autoanswer flowchart and timings.

09833-10A

Figure 7a. Autoanswer Flowchart

09833-11A

Figure 7b. Autoanswer Timings

Call Progress Tone Detection (CPTD)

The CPTD filter passes call progress tones from all the major Post Telephone and Telegraphs (PTTs). The cadences (temporal patterns) of \overline{CD} will identify the following signals:

- Primary Dial Tone
- Secondary Dial Tone
- Ringback Signal
- Network Busy Signal
- Busy Signal

Each country's PTT may have different requirements for the cadences of these call progress tones.

Dual-Tone Multi-Frequency (DTMF) Tone Generation

The Am79101 transmitter can generate the basic 3×4 matrix, as shown in Table 4. According to the Bell specifications, the minimum duration for the DTMF digit is 50 ms. The minimum interdigit interval (silence) is 45 ms. The minimum time from the beginning of one DTMF digit to the next is 100 ms. It is common practice to extend the DTMF digit duration to insure detection by the central office.

Table 4. DTMF Tone Combinations

		High-Group Frequencies (Hz)		
		1209	1336	1477
Low-Group Frequencies (Hz)	697	1	2	3
	770	4	5	6
	852	7	8	9
	941	*	0	#

Once in the Call Mode, \overline{RTS} controls the duration of the DTMF tone. With $\overline{DTR} = \text{Low}$ and the desired digit applied to the MC pins, setting $\overline{RTS} = \text{Low}$ will generate the DTMF tone at TC until \overline{RTS} is set High. The user has complete control of the DTMF tone duration and the interdigit interval. Inputs to the MC pins should be changed while \overline{RTS} is High and \overline{DTR} is Low.

Answer Tone Detection (ATD)

The Am79101 receiver can detect answer tones for the Bell 103, 202, and CCITT V.21/V.23 modes. $\overline{CD} = \text{Low}$ indicates the presence of a valid answer tone. RD distinguishes between the three answer tones as shown below. This feature allows mode matching with the remote modem. In the CCITT V.21/V.23 modes, X at RD indicates toggling between High and Low.

Modem Mode	Answer Tone Frequency (Hz)	\overline{CD}	RD
Bell 103	2225	Low	High
Bell 202	2025	Low	Low
CCITT V.21/V.23	2100	Low	X

The Carrier Detect Call thresholds (V_{CDCON} , V_{CDCOFF}) for valid answer tone detection are internally set to be higher than those in the Data Mode. This eliminates the need for an external attenuator in the Call Mode to prevent noise from being decoded as an answer tone.

Answer Tone Generation (ATG)

Answer tones are generated according to the modem mode selected, as listed in the ATD section. $\overline{RTS} = \text{Low}$ controls the answer tone duration and $\overline{RTS} = \text{High}$ controls the silence intervals. Silence interval before the answer tone is required by various governmental agencies for billing delay purposes.

DATA TRANSMISSION*

Full-Duplex

Following call establishment, full-duplex data transmission can be started by either the called or calling modem. If the connection has been established and the modem is looping through point A in Figure 8a, it no longer matters which is the called and which is the calling modem. Data transmission is initiated by setting \overline{RTS} Low. At this time the TD input will be released and a modulated carrier can appear at the TC output. Following a delay, t_{RCON} , \overline{CTS} changes to Low. At this time, data may be transmitted through TD. It is common protocol for the user to always present a Mark at TD before \overline{RTS} is asserted and during the t_{RCON} delay.

Data transmission continues until \overline{RTS} is set High. Following a short delay, t_{RCOFF} , \overline{CTS} changes to High. As soon as \overline{RTS} goes High, TD is ignored and TC is set to 0.0 V (silence). After \overline{CTS} changes to High, the state machine returns to point A in Figure 8a.

Half-Duplex

When a half-duplex mode is selected (202 or V.23), data transmission can be either on the main channel at 1200/600 bps or on the back-channel at 575/150 bps. In normal half-duplex operation, a single modem is either transmitting on the main and receiving on the back-channel or vice-versa. In the Am79101, control of the transmitter and receiver filters to the proper channel is performed by \overline{RTS} . When \overline{RTS} is asserted, the transmitter filters and synthesizer are set to transmit on the main channel; the receiver filters are set to receive on the back-channel. Therefore, whenever \overline{RTS} is Low, \overline{BRTS} should not be asserted since the transmitter cannot be used for the back-channel. When \overline{RTS} is High and a half-duplex mode is selected, the transmitter filters and synthesizer are set to the back-channel; the receiver filters are set to the main channel. If \overline{RTS} and \overline{BRTS} are

*All timing delays are listed in Table 5.

asserted simultaneously, \overline{RTS} will take precedence. However, if \overline{BRTS} is asserted before RTS and the back-channel data transmission sequence has been entered (Figure 8b), \overline{RTS} will be ignored until \overline{BRTS} is set High.

The state machine sequences for main and back-channel transmission differ slightly and are depicted in Figures 8a and 8b. Assume the state machine is idling through point A in Figure 8a.

Main Channel

This transmission sequence is entered if a 202 or V.23 mode is selected and RTS is asserted. Since the receiver is now forced to the back-channel, the RD signal is clamped to a Mark and the \overline{CD} signal is clamped High. The TD input is released and a carrier appears at the TC output which follows the Mark/Space applied to TD. \overline{RTS} going Low initiates a delay, t_{RCOFF} , at the end of which the \overline{CTS} output goes Low. When \overline{CTS} goes Low, data may be transmitted through TD. Data transmission continues until RTS is set High. At this time several events are initiated. First a delay, t_{RCOFF} , is initiated, at the end of which \overline{CTS} goes High. TD is ignored as soon as RTS goes High. If a 202 mode or V.23 soft turn-off mode is selected, a soft turn-off tone appears at TC for a time, t_{STO} , followed by silence (0.0 V). For both 202 and V.23 modes, a squelch period, t_{SQ} , is initiated when \overline{RTS} goes High. During this period the \overline{CD} output is clamped High, forcing the RD output to a Mark condition. The squelch period begins as soon as \overline{RTS} goes High and thus overlaps both t_{RCOFF} and t_{STO} . At the end of the squelch period, the state machine returns to the idle loop at point A in Figure 8a. The reasons for squelch and soft turn-off are as follows:

Soft turn-off: When \overline{RTS} goes High at the end of a message, transients occur that may cause spurious Space signals to be received at the remote modem. During soft turn-off, the modem transmits a soft carrier frequency for a period, t_{STO} , after \overline{RTS} goes High. This results in a steady Mark on the RD line of the remote modem.

Squelch: The local receiver must be turned off after RTS is High, until the start of carrier detect, so that line transients are not demodulated. The process of disabling the receiver after \overline{RTS} goes High is called squelching.

Back-channel

This transmission sequence, shown in Figure 8b, is entered if a 202 or V.23 mode is selected, RTS is High, and \overline{BRTS} is asserted. The BCD output is forced High and the BRD output is clamped to a Mark. The BTD input is released and a carrier appears at the TC output, which follows the Mark/Space applied to BTD. Setting \overline{BRTS} Low initiates a delay, t_{BRCON} , at the end of which the \overline{BCTS} output goes Low. When \overline{BCTS} goes Low, data

may be transmitted through BTD. Data transmission continues until \overline{BRTS} is set High. BTD is immediately ignored and TC is silenced (set to 0.0 V). Following a short delay, t_{BRCOFF} , \overline{BCTS} goes High. The signals \overline{BCD} and BRD are released and the state machine returns to idle at point A of Figure 8a. In 202 5-bps back-channel mode, BTD should be tied High. Then \overline{BRTS} controls the On/Off keying modulation. When \overline{BRTS} is Low, a 387-Hz tone appears at TC; when \overline{BRTS} is High, 0.0 V appear at TC.

DATA RECEPTION*

Data reception is controlled by State Machine 2 and depicted in Figure 9. At power-on, the machine enters initial conditions and remains there until \overline{DTR} is set Low. It then loops until either $\overline{CD} = \text{Low}$ or $\overline{BCD} = \text{Low}$ occurs.

Full-Duplex

In full-duplex data reception, carrier may appear at any time after the phone connection has been established. Reception is independent of transmission. When the receiver detects a valid carrier for at least the time, t_{CDON} , the output \overline{CD} goes Low, and valid data can be obtained at RD. Data is received until the receiver detects loss of carrier for at least the time, t_{CDOFF} . At this time \overline{CD} goes High and RD is clamped to a Mark. The state machine returns to the idle loop at point E.

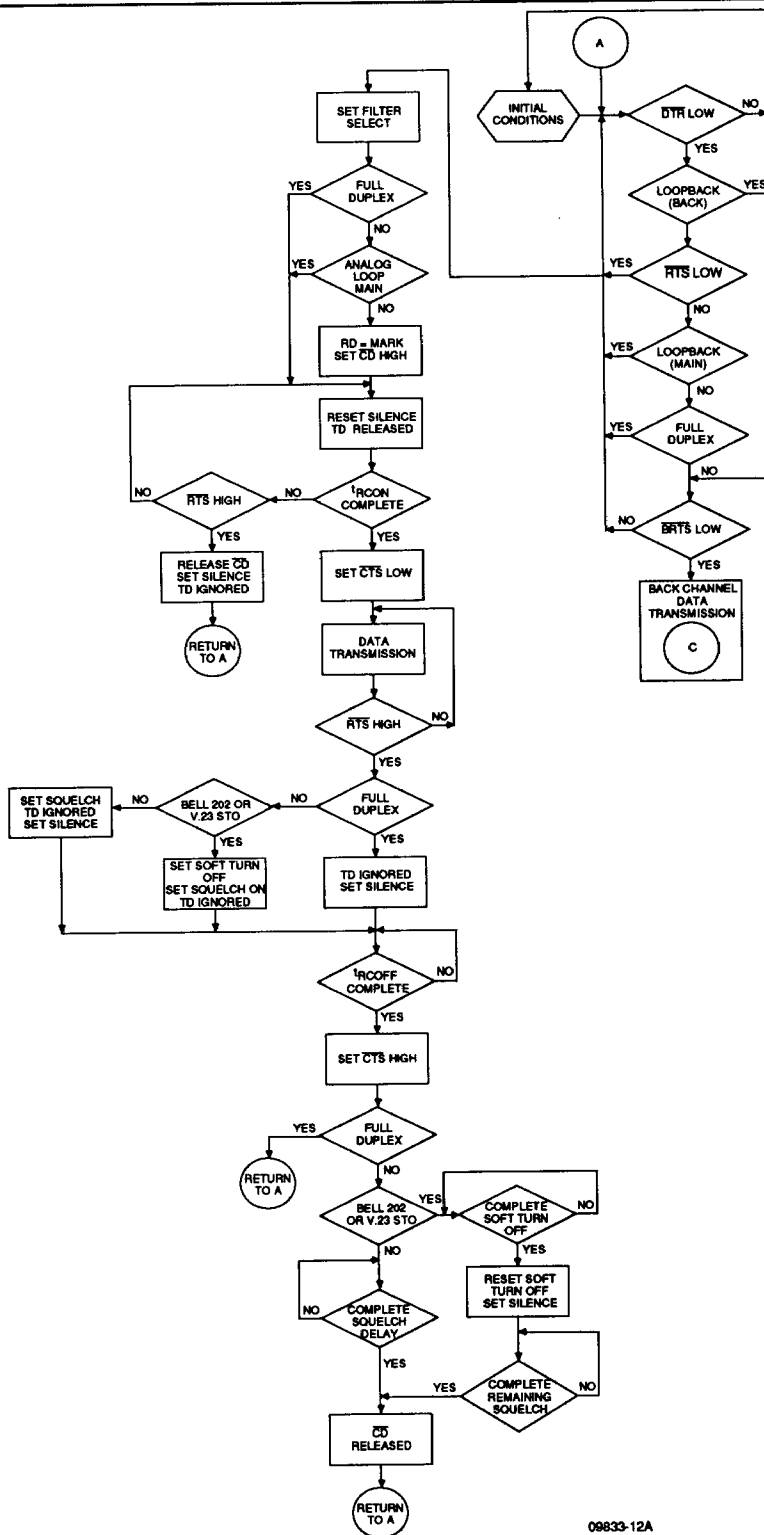

Half-Duplex

As discussed in the Data Transmission section, when a half-duplex mode has been selected, \overline{RTS} controls whether the main channel is transmitting or receiving. The back-channel can only do the opposite from the main channel. If RTS is High, \overline{CD} may be activated and the data reception sequence is identical to that discussed above for full-duplex reception. As long as \overline{RTS} remains High, \overline{BCD} will never be activated. If RTS is Low, then \overline{CD} will never be activated. Instead, the receiver will look for a valid carrier in the back-channel frequency band. If a valid carrier exists for at least the time, t_{BCDON} , \overline{BCD} changes to Low, and valid data can be obtained at BRD. Data is received until the receiver detects loss of back-channel received signal for at least the time, t_{BCDOFF} . At this time, \overline{BCD} goes High. BRD is clamped to a Mark if V.23 mode or 202 150-bps back-channel mode is selected. For 202 5-bps back-channel mode, \overline{BCD} represents the received data. BRD can be ignored. The state machine returns to the idle loop at point E.

LOOPBACK

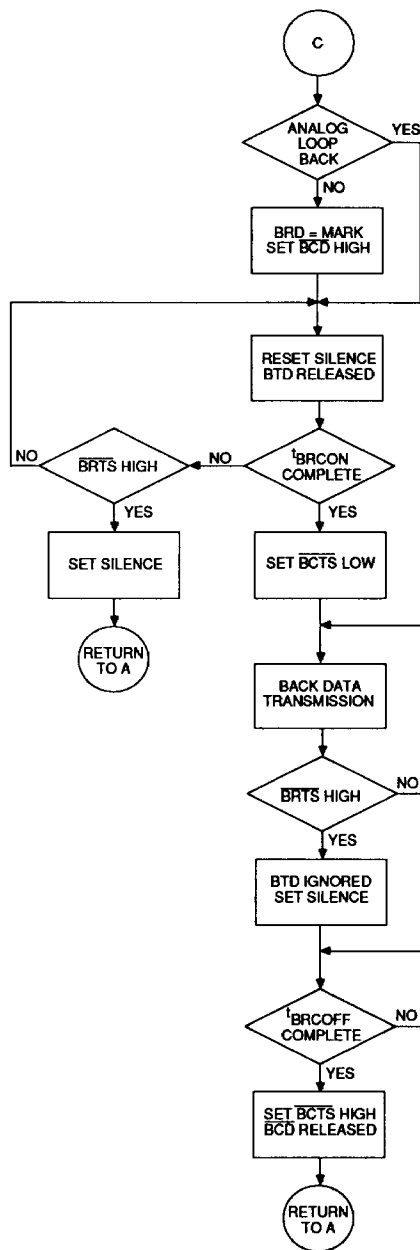

Eleven modes exist to allow both analog and digital loopback for each modem specification met by the Am79101. These loopback modes allow character-echo testing, but are not intended for 4-wire full-duplex applications. When a loopback mode is selected, the

*All timing delays are listed in Table 5.

09833-12A

Figure 8a. Transmit Main Channel State Diagram

09833-13A

Figure 8b. Transmit Back-Channel State Diagram

signal processing (filters, etc.) for both the transmitter and receiver is set to process the same channel or frequency band. This allows the analog output, TC, and the analog input, RC, to be connected externally for local analog loopback. Alternately, the digital data signals, TD and RD or BTD and BRD, can be connected externally, allowing a remote modem to test the local

modem with its digital data signals looped back.

When a loopback mode is selected, the state machine sequences are altered slightly. If a half-duplex loopback mode is selected (202 or V.23), the local $\overline{CD}/\overline{BCD}$ is not forced High when $\overline{RTS}/\overline{BRTS}$ is asserted.

CLOCK GENERATION

Master timing of the modem is provided by either a crystal connected to the XTAL₁ and XTAL₂ pins or an external clock applied to XTAL₁.

Crystal

When a crystal is used it should be connected as shown in Figure 14a. The crystal should be a parallel resonance type, and its value must be 2.4576 MHz \pm .01%. A list of crystal suppliers is shown below.

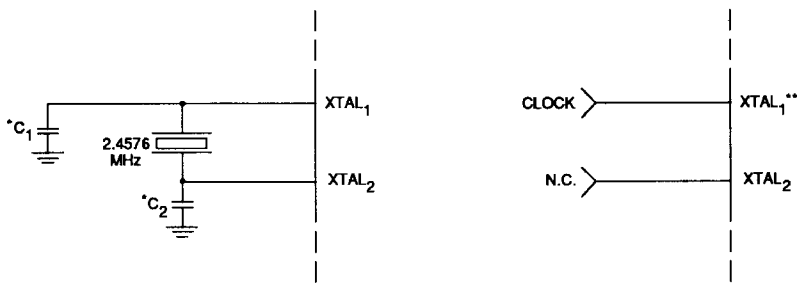

External Clock

This clock signal could be derived from one of several crystal-driven baud rate generators. It should be connected to XTAL₁, and XTAL₂ must be left floating. The timing parameters required of this clock are shown in Figure 14b and the values are listed in Table 6.

Crystal Information (f = 2.4576 MHz)

Manufacturer	P/N	C ₁	C ₂
M-Tron	MP-2	10 pF	20 pF
Monitor Products	MM-33	10 pF	20 pF

Note: Rise time of V_{CC} must be greater than 5 ms to insure proper crystal oscillator start-up.

*Capacitor values vary with different crystal manufacturers.

**The input impedance of this pin appears as 5 to 10 pF to ground in parallel with at least 1 MΩ.

Figure 14a. Clock Generation

09833-19A

Figure 14b. External Clock

Table 6. Clock Parameters

Symbol	Parameters	Min	Typ	Max	Unit
t_{CV}	Clock Period	406.86	406.9	406.94	ns
t_{CH}	Clock High Time	165			ns
t_{CL}	Clock Low Time	165			ns
t_{CR}	Clock Rise Time			20	ns
t_{CF}	Clock Fall Time			20	ns

RESET MODES

Automatic Power-On Reset—Figure 15a suggests a circuit to initiate the internal reset sequence automatically whenever V_{CC} is applied. V_{CC} rise time should be faster than one half the RC time constant. The Am79101 contains a diode to discharge the capacitor when $V_{CC} = 0$ V.

RESET Input—The Am79101 can be forced into the internal reset sequence by setting $\overline{\text{RESET}}$ Low for at least one clock period.

Note that V_{CC} must be at least +3.5 V for proper reset operation. Between repetitive reset pulses, $\overline{\text{RESET}}$ must be High for at least 1 μs , as shown in Figure 15b.

Figure 15a. Automatic Reset

Figure 15b. Reset Timing Diagrams

Upon device initialization or mode change, $\overline{\text{DTR}}$ must be brought High for a time $t_{MSU} > 100 \mu\text{s}$, as shown in Figure 16.

POWER SUPPLY

For maximum performance, power supply bypassing should be used. V_{CC} should be decoupled to DGND and V_{BB} to AGND as shown in Figure 17. The 0.01 μF ceramic disc capacitors should be mounted as physically close to the pins as possible.

Figure 16. Mode Setup

Figure 17. Power Supply Connections

ABSOLUTE MAXIMUM RATINGS

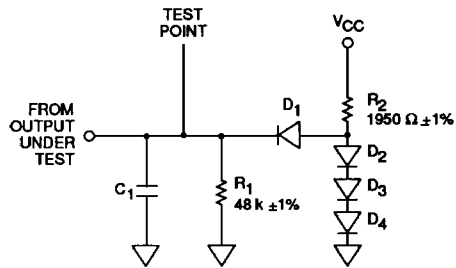

Storage Temperature	-65 to +125°C
Ambient Temperature with Power Applied	
Commercial (C) Devices	0 to +70°C
Industrial (I) Devices	-40 to +85°C
Extended (E) Devices	-55 to +125°C
V_{CC} with Respect to DGND	+6 V / -0.4 V
V_{BB} with Respect to DGND	-6 V / +0.4 V
All Signal Voltages with Respect to DGND	+5 V

Stresses above those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent device failure. Functionality at or above these limits is not implied. Exposure to absolutely maximum ratings for extended periods may affect device reliability.

OPERATING RANGES

Positive Supply Voltage (V_{CC})	+4.75 to +5.25 V
Negative Supply Voltage (V_{BB})	-4.75 to -5.25 V
AGND, DGND Offset	-50 to +50 mV
Commercial (C) Devices	0 to +70°C
Industrial (I) Devices	-40 to +85°C
Extended (E) Devices	-55 to +125°C

Operating ranges define those limits over which the functionality of the device is guaranteed.

Standard Load Circuit

- Notes:
1. $C_1 = 50 \text{ pF}$ including stray and wiring capacitance
 2. All diodes are 1N3064 or equivalent
 3. All resistors are 1/8 W
 4. $V_{cc} = 5 \text{ V} \pm 5\%$

Figure 19. Out-of-Band Transmitter Energy**

APPLICATIONS

An intelligent Autodial, Autoanswer FSK modem can be easily built with the Am79101. Figures 20 and 21 show implementations of full-duplex and half-duplex modes.

For the full-duplex 103/V.21 modes, a single baud rate (300 bps) is used. With its on-chip UART, the single-chip microcontroller Am8051 provides a simple solution. The Am79101's RS-232C signals and setup controls are connected to the Am8051 as shown in Figure 20. MC_4 conveniently controls the on-hook relay in the DAA circuit. $MC_4 = 0$ activates off-hook and $MC_4 = 1$ keeps on-hook during analog loopback for local testing. If DTMF dialing is not permitted on a particular telephone network, the relay contact can be rapidly made and broken for pulse dialing.

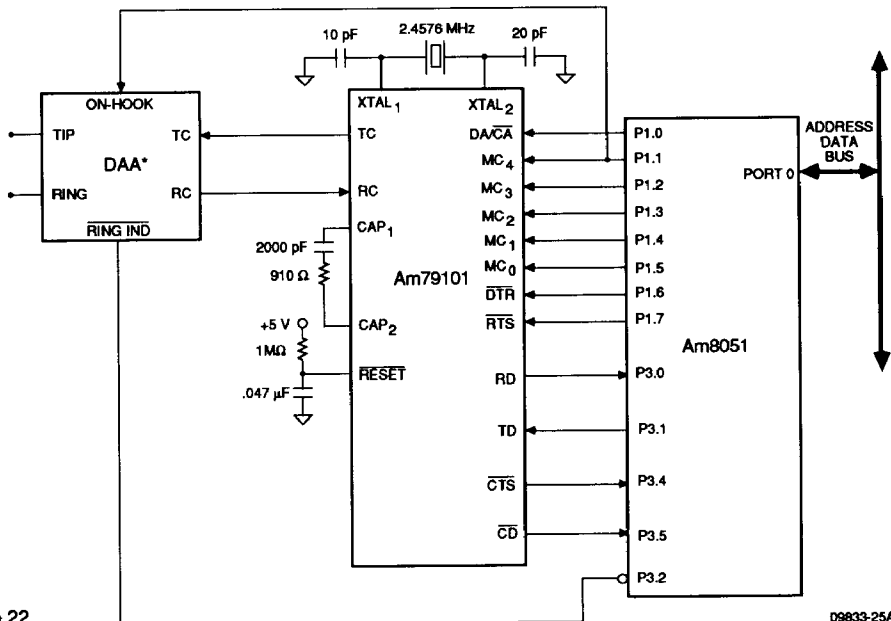

Automatic answering of incoming calls is serviced like an interrupt routine by the Am8051. Upon ringing, the DAA interrupts the Am8051, which then places the relay

off-hook and the Am79101 in the Call Mode to generate the answer tone. After the call is established or answered, the Am8051 has complete control to start data transfer.

For the half-duplex 202/V.23 modes, two different baud rates (1200 bps and 75/150 bps) are used for the main and back-channels. A dual-UART system is required. Figure 21 shows an implementation with the Am8051 and the dual-channel Serial Communication Controller AmZ8530. The AmZ8530 can also be used with other CPUs, such as the Z80, 8080, 6800 and 68000.

The internal hybrid of the Am79101 performs the 4- to 2-wire conversion to simplify the user interface to the switched telephone network. The analog signals TC and RC are coupled directly into the DAA circuit, as shown in Figure 22.

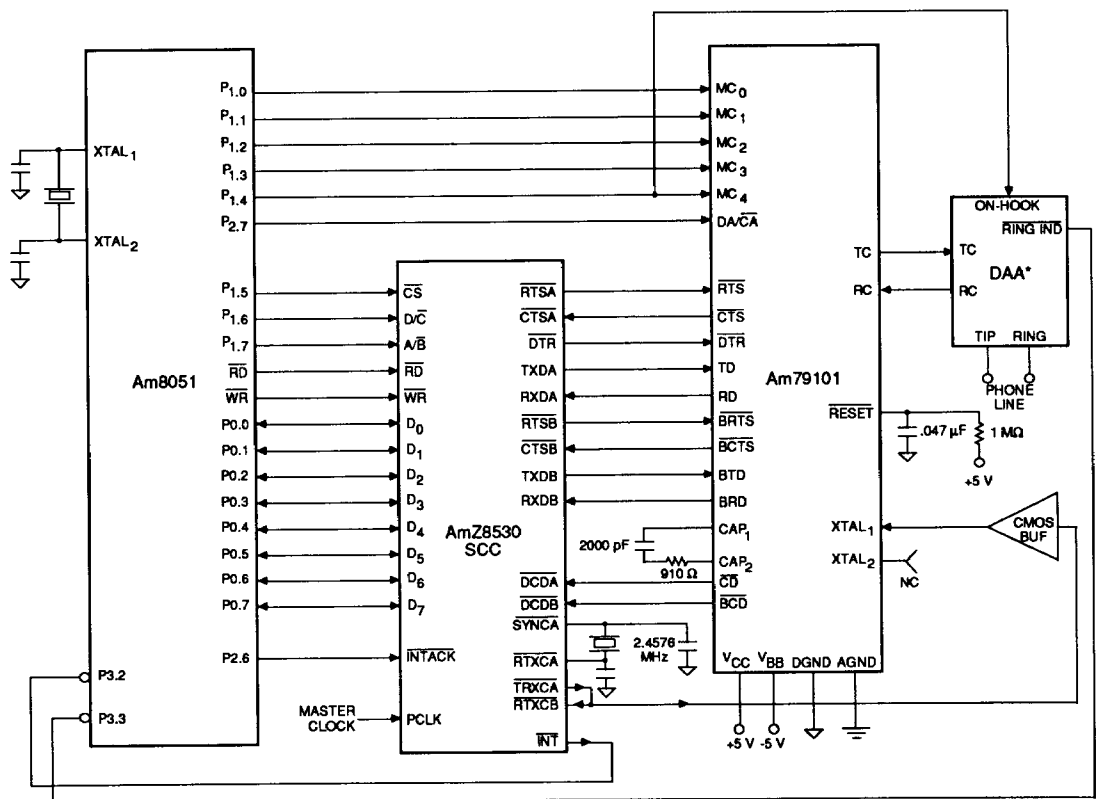

For additional information, refer to AMD's 1988 Modem Technical Manual (PID# 09560A).

Advanced Micro Devices reserves the right to make changes in its product without notice in order to improve design or performance characteristics. The performance characteristics listed in this document are guaranteed by specific tests, guard banding, design and other practices common to the industry. For specific testing details, contact your local AMD sales representative. The company assumes no responsibility for the use of any circuits described herein.
