

# MAQ473

## 9-Bit to 14-Bit, MagAlpha Automotive Angle Sensor with ABZ Incremental and PWM Outputs

### DESCRIPTION

The MAQ473 detects the absolute angular position of a permanent magnet, typically a diametrically magnetized cylinder on a rotating shaft. Fast data acquisition and processing provide accurate angle measurement at speeds from 0rpm to 60,000rpm.

The MAQ473 supports a wide range of magnetic field strengths and spatial configurations. Both end-of-shaft and off-axis (side-shaft mounting) configurations are supported.

The MAQ473 features magnetic field strength detection with programmable thresholds to allow sensing of the magnet position relative to the sensor for creation of functions such as the sensing of axial movements or for diagnostics.

The on-chip non-volatile memory provides storage for configuration parameters, including the reference zero-angle position, ABZ encoder settings, and magnetic field detection thresholds.

The MAQ473 is AEC-Q100 qualified, and is available in a QFN-16 (3mmx3mm) package.

### FEATURES

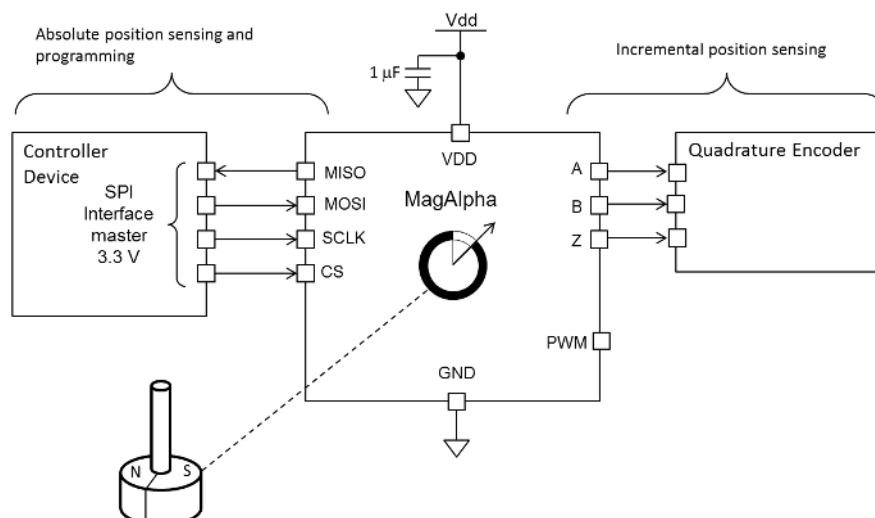

- 9-Bit to 14-Bit Resolution Absolute Angle Encoder
- Contactless Sensing for Long Lifespan
- SPI Serial Interface with Parity Bit for Angle Readout and Chip Configuration
- Configuration Programmable Magnetic Field Strength Detection for Diagnostic Checks
- Incremental 12-Bit ABZ Quadrature Encoder Interface with Programmable Pulses Per Turn from 1 to 1024
- 14-Bit PWM Output
- 3.3V, 12mA Supply Current
- -40°C to +150°C Operating Temperature
- Available in a QFN-16 (3mmx3mm) Package with Wettable Flanks
- Available in AEC-Q100 Grade 1

### APPLICATIONS

- Automotive
- Angle Encoders
- Automotive Angle or Speed Sensors
- Robotics

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simply, Easy Solutions" are registered trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

### TYPICAL APPLICATION

### ORDERING INFORMATION

Part Number*	Package	Top Marking	MSL Rating
MAQ473GQE-AEC1	QFN-16 (3mmx3mm)	See Below	1

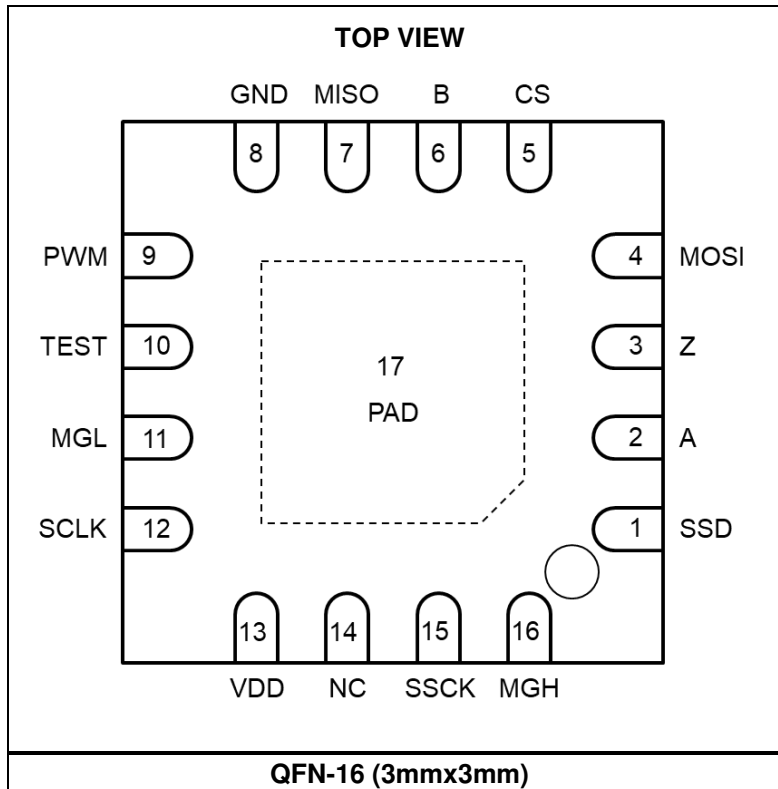

\* For Tape & Reel, add suffix -Z (e.g. MAQ473GQE-AEC1-Z).

### TOP MARKING

**BNXY**  
**LLLL**

BNX: Product code of MAQ473GQE  
Y: Year code  
LLLL: Lot number

### PACKAGE REFERENCE

## PIN FUNCTIONS

Pin #	Name	Description
1	SSD	<b>Data out (SSI).</b>
2	A	<b>Incremental output.</b>
3	Z	<b>Incremental output.</b>
4	MOSI	<b>Data in (SPI).</b> The MOSI pin has an internal pull-down resistor.
5	CS	<b>Chip select (SPI).</b> The CS pin has an internal pull-up resistor.
6	B	<b>Incremental output.</b>
7	MISO	<b>Data out (SPI).</b> MISO has an internal pull-down resistor that is enabled when the device is in a high-impedance state.
8	GND	<b>Supply ground.</b>
9	PWM	<b>PWM output.</b>
10	TEST	<b>Connect to ground.</b>
11	MGL	<b>Digital output indicating field strength below the MGLT level.</b>
12	SCLK	<b>Clock (SPI).</b> The SCLK pin has an internal pull-down resistor.
13	VDD	<b>3.3V supply.</b>
14	NC	<b>No connection.</b> Leave the NC pin unconnected.
15	SSCK	<b>Clock (SSI).</b> The SSCK pin has an internal pull-down resistor.
16	MGH	<b>Digital output indicating field strength above the MGHT level.</b>
17	Exposed pad	<b>Recommend not to solder.</b> Leave floating.

### ABSOLUTE MAXIMUM RATINGS <sup>(1)</sup>

Supply voltage .....	-0.5V to +4.6V
Input pin voltage (V <sub>I</sub> ) .....	-0.5V to +6.0V
Output pin voltage (V <sub>O</sub> ) .....	-0.5V to +4.6V
Continuous power dissipation (T <sub>A</sub> = 25°C) <sup>(2)</sup>	.....2.0W
Junction temperature .....	160°C
Lead temperature .....	260°C
Storage temperature .....	-65°C to +160°C

### ESD Ratings

Human body model (HBM) .....	2kV
Charged device model (CDM) .....	750V

<b>Thermal Resistance <sup>(3)</sup></b>	<b>θ<sub>JA</sub></b>	<b>θ<sub>JC</sub></b>
QFN-16 (3mmx3mm) .....	50.....	12 ... °C/W

#### Notes:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the maximum junction temperature T<sub>J</sub> (MAX), the junction-to-ambient thermal resistance θ<sub>JA</sub>, and the ambient temperature T<sub>A</sub>. The maximum allowable continuous power dissipation at any ambient temperature is calculated by P<sub>D</sub> (MAX) = (T<sub>J</sub> (MAX) - T<sub>A</sub>) / θ<sub>JA</sub>.
- 3) Measured on JESD51-7, 4-layer PCB.

## ELECTRICAL CHARACTERISTICS

Parameter	Symbol	Condition	Min	Typ	Max	Units
<b>Recommended Operating Conditions</b>						
Supply voltage	V <sub>DD</sub>		3.0	3.3	3.6	V
Supply current	I <sub>DD</sub>	From -40°C to +125°C	10.2	12	13.8	mA
Operating (ambient) temperature	T <sub>A</sub>		-40		+150	°C
Applied magnetic field	B		30	60		mT

## GENERAL CHARACTERISTICS

$V_{DD} = 3.3V$ ,  $45mT < B < 100mT$ ,  $T_A = -40^{\circ}C$  to  $+125^{\circ}C$ , unless otherwise noted.

Parameter	Symbol	Condition	Min	Typ	Max	Units
<b>Absolute Output (Serial)</b>						
Effective resolution ( $\pm 3\sigma$ )		filter window $\tau = 64\mu s$	9.0	9.8	10.5	bits
		filter window $\tau = 16ms$	13.0	13.8	14.5	bits
Noise root mean square (RMS)		filter window $\tau = 64\mu s$	0.04	0.07	0.12	deg
		filter window $\tau = 16ms$	0.003	0.004	0.007	deg
Refresh rate			850	980	1100	kHz
Data output length			16		16	bits
<b>Response Time</b>						
Start-up time <sup>(4)</sup>		filter window $\tau = 64\mu s$			0.6	ms

Rising edge slew rate <sup>(4)</sup>	$t_R$	$CL = 50pF$		0.7		V/ns
Falling edge slew rate <sup>(4)</sup>	$t_F$	$CL = 50pF$		0.7		V/ns

**Notes:**

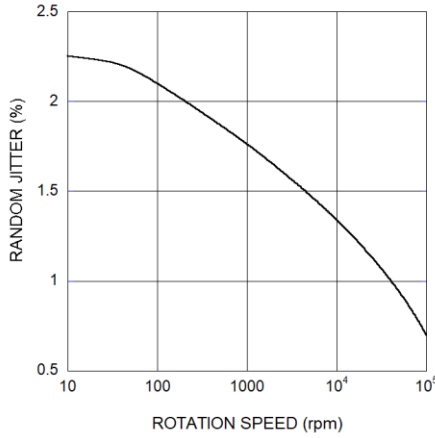

- 4) Guaranteed by design.
- 5) Guaranteed by characterization.

# TYPICAL CHARACTERISTICS

$V_{DD} = 3.3V$ ,  $T_A = 25^\circ C$ , unless otherwise noted.

## ABZ Jitter

PPT = 255,  $\tau = 1ms$

## Current Consumption

## Filter Transfer Function

$\tau = 16ms$

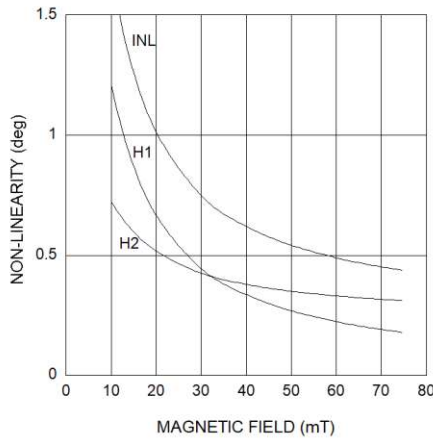

## Error Curve

50mT

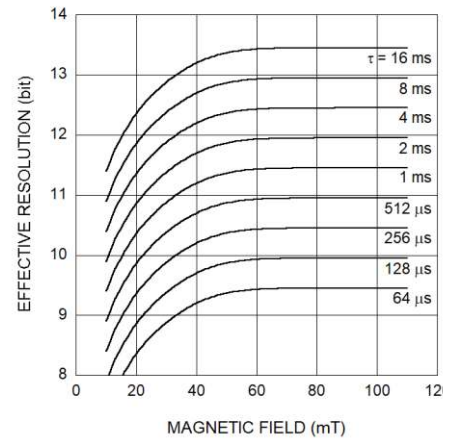

## Nonlinearity (INL and Harmonics)

## Effective Resolution

$3\sigma$

## Noise Spectrum

50mT and  $\tau = 16ms$

### FUNCTIONAL BLOCK DIAGRAM

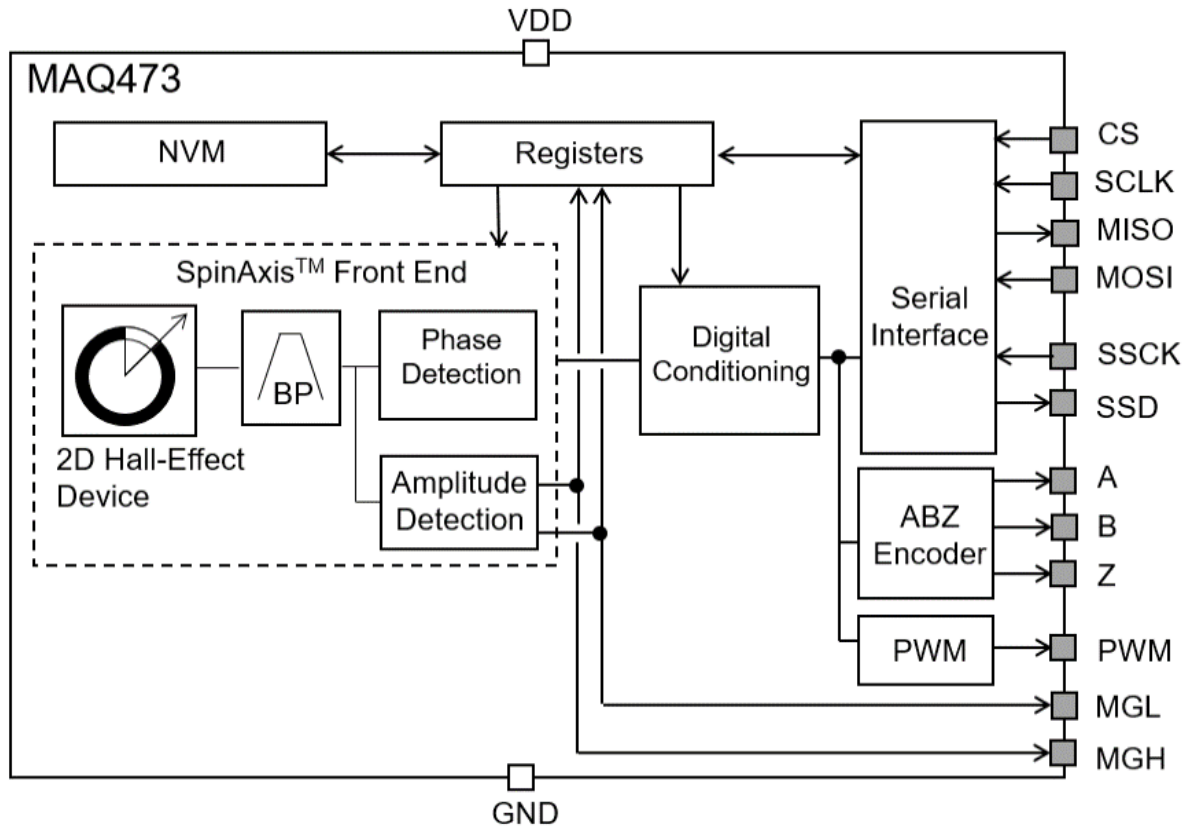

Figure 1: Functional Block Diagram

## OPERATION

### Sensor Front End

The magnetic field is detected with integrated Hall devices located in the center of the package. The angle is measured using MPS’s proprietary SpinAxis™ method, which directly digitizes the direction of the field without the need for complex arctangent computation or feedback loop-based circuits (interpolators).

The SpinAxis™ method is based on phase detection, and generates a sinusoidal signal with a phase that represents the angle of the magnetic field. The angle is then obtained by a time-to-digital converter, which measures the time between the zero crossing of the sinusoidal signal and the edge of a constant waveform (see Figure 2). The time-to-digital is outputted from the front end to the digital conditioning block.

**Figure 2: Phase Detection Method across the Sine Waveform (Top) and Time-to-Digital Converter Clock (Bottom)**

The output of the front end delivers a digital number proportional to the angle of the magnetic field at the rate of 1MHz in a straightforward, open-loop manner.

### Digital Filtering

The front-end signal is further treated to achieve the final effective resolution. This treatment does not add any latency in steady conditions. The filter transfer function can be calculated with Equation (1):

$$H(s) = \frac{1 + 2Ts}{(1 + Ts)^2} \quad (1)$$

Where  $\tau$  is the filter time constant related to the cutoff frequency by:  $\tau = 0.38 / f_{CUTOFF}$ .

See the General Characteristics section on page 5 for the value of  $f_{CUTOFF}$ .

### Sensor Magnet Mounting

The MAQ473’s sensitive area (where the Hall devices are placed) is confined within a region less than 100 $\mu$ m wide and has multiple integrated Hall devices. This volume is located both horizontally and vertically within 50 $\mu$ m of the center of the QFN package. The sensor detects the angle of the magnetic field projected in a plane parallel to the package’s upper surface. This means that the only relevant magnetic field is the in-plane component (X and Y components) in the mid-point of the package.

By default, when looking at the top of the package, the angle increases when the magnetic field rotates clockwise. Figure 3 shows the zero angle of the unprogrammed sensor, where the plus sign indicates the sensitive point. Both the rotation direction and the zero angle can be programmed.

**Figure 3: Detection Point and Default Positive Direction**

This type of detection provides flexibility for angular encoder design. The sensor only requires the magnetic vector to lie within the sensor plane with a field amplitude of at least 30mT. The MAQ473 can work with fields smaller than 30mT, but the linearity and resolution performance may deviate from the specifications. The most straightforward mounting method is to place the MAQ473 sensor on the rotation axis of a permanent magnet (e.g. a diametrically magnetized cylinder) (see Figure 4 on page 10).

The recommended magnet is a Neodymium alloy (N35) cylinder with dimensions Ø5x3mm, inserted into an aluminum shaft with a 1.5mm air gap between the magnet and the sensor (surface of package). For good linearity, position the with a precision of 0.5mm.

**Figure 4: End-of-Shaft Mounting**

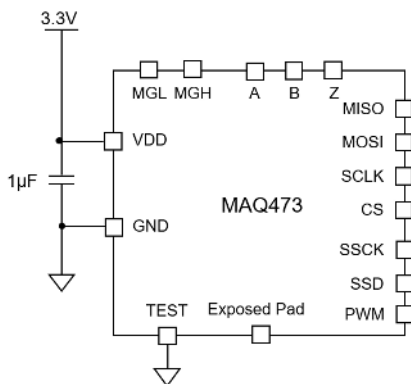

If the end-of-shaft position is not available, the sensor can be positioned away from the rotation axis of a cylinder or ring magnet (see Figure 5). In this case, the magnetic field angle is not directly proportional to the mechanical angle. The MAQ473 can be adjusted to compensate for this effect and recover the linear relation between the mechanical angle and the sensor output. With multiple pole pair magnets, the MAQ473 indicates multiple rotations for each mechanical turn.

**Figure 5: Side-Shaft Mounting**

### Electrical Mounting and Power Supply Decoupling

It is recommended to place a 1µF decoupling capacitor close to the sensor with a low-impedance path to GND (see Figure 6).

**Figure 6: Supply Decoupling Connection**

In general, the MAQ473 works well with or without the exposed pad connected. For optimum electrical, thermal, and mechanical conditions, it is recommended that the exposed pad be connected to ground.

### Serial Interface

The sensor supports the serial peripheral interface (SPI) standard for angle reading and register programming. Alternatively, the synchronous serial interface (SSI) bus can be used for angle reading (programming through the SSI is not supported).

The data length is 16 bits. For checking the integrity of the data received (angle or register content) the master sends a 17th clock count and receives a parity bit.

### SPI

The SPI is a four-wire, synchronous, serial communication interface. The MAQ473 supports SPI Mode 3 and Mode 0 (see Table 1 and Table 2). The SPI mode (0 or 3) is detected automatically by the sensor, and therefore does not require any action from the user. The maximum clock rate supported on the SPI is 25MHz. There is no minimum clock rate. Real-world data rates depend on the PCB layout quality and signal trace length. See Figure 7 and Table 3 on page 11 for SPI timing.

**Table 1: SPI Specification**

	Mode 0	Mode 3
<b>SCLK Idle State</b>	Low	High
<b>Data Capture</b>	On SCLK rising edge	
<b>Data Transmission</b>	On SCLK falling edge	
<b>CS Idle State</b>	High	
<b>Data Order</b>	MSB first	

**Table 2: SPI Standard**

	Mode 0	Mode 3
<b>CPOL</b>	0	1
<b>CPHA</b>	0	1
<b>Data Order (DORD)</b>	0 (MSB first)	

All commands to the MAQ473 (whether for writing or reading register content) must be transferred through the SPI MOSI pin and must be 16 bits long.

See the SPI Communication section on page 12 for details.

**Figure 7: SPI Timing Diagram**

**Figure 8: Minimum Idle Time**

**Table 3: SPI Timing**

Parameter <sup>(6)</sup>	Description	Min	Max
$t_{IDLE\_ANGLE}$	Idle time between two subsequent angle transmissions	150ns	-
$t_{IDLE\_REG}$	Idle time before and after a register readout	750ns	-
$t_{NVM}$	Idle time between a write command and a register readout (delay necessary for non-volatile memory update)	20ms	-
$t_{CSL}$	Time between the CS falling edge and SCLK falling edge	80ns	-
$t_{SCLK}$	SCLK period	40ns	-
$t_{SCLKL}$	Low level of SCLK signal	20ns	-
$t_{SCLKH}$	High level of SCLK signal	20ns	-
$t_{CSH}$	Time between SCLK rising edge and CS rising edge	25ns	-
$t_{MISO}$	SCLK setting edge to data output valid	-	15ns
$t_{MOSI}$	Data input valid to SCLK reading edge	15ns	-

**Note:**

6) Guaranteed by design.

### SPI Communication

The sensor supports three types of SPI operation:

- Read angle
- Read configuration register
- Write configuration register

Each operation has a specific frame structure, described below.

#### SPI Read Angle

Every 1µs, new data is transferred into the output buffer. The master device triggers the reading by pulling CS low.

When a trigger event is detected, the data remains in the output buffer until the CS signal is de-asserted (see Table 4).

**Table 4: Sensor Data Timing**

Event	Action
CS falling edge	Start reading and freeze the output buffer
CS rising edge	Release the output buffer

Figure 9 shows a diagram of a full SPI angle reading. Figure 10 shows a partial SPI angle reading. A full angle reading requires 16 clock pulses. The sensor MISO line returns:

The MagAlpha family has sensors with different features and levels of resolution. See the data output length section in the General Characteristics section on page 5 for the number of useful bits delivered at the serial output. If the data length is less than 16, the rest of the bits sent are 0s. For example, a data output length of 12 bits means that the serial output delivers a 12-bit angle value with 4 bits of 0s padded at the end (the MISO state remains 0). If the master sends 16 clock counts, the MAQ473 replies with:

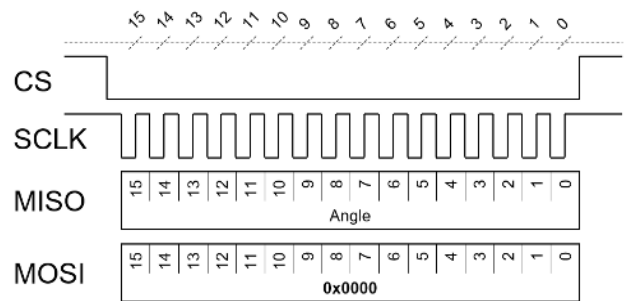

Angle reading can be therefore optimized without any loss of information by reducing the number of clock counts. In the case of a 12-bit data output length, only 12 clock counts are required to get the full sensor resolution.

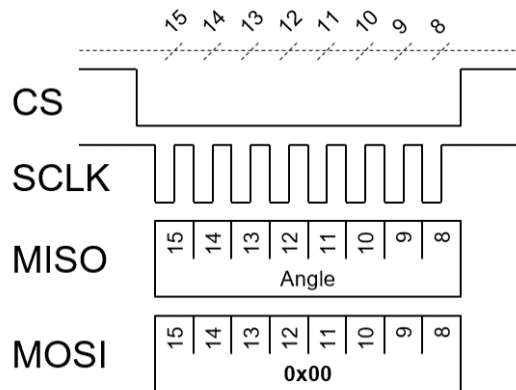

If less resolution is needed, the angle can be read by sending even fewer clock counts (since the MSB is first).

In case of fast reading, the MAQ473 continues sending the same data until the data is refreshed. See the refresh rate section in the General Characteristics section on page 5.

**Figure 9: Full 16-Bit SPI Angle Reading Diagram**

**Figure 10: Partial 8-Bit SPI Angle Reading Diagram**

**SPI Read Register**

A read register operation consists of two 16-bit frames. The first frame sends a read request, which contains the 3-bit read command (010) followed by the 5-bit register address. The last 8 bits of the frame must all be set to 0. The second frame returns the 8-bit register value (MSB byte).

First 16-bit SPI frame (read request):

Second 16-bit SPI frame (response):

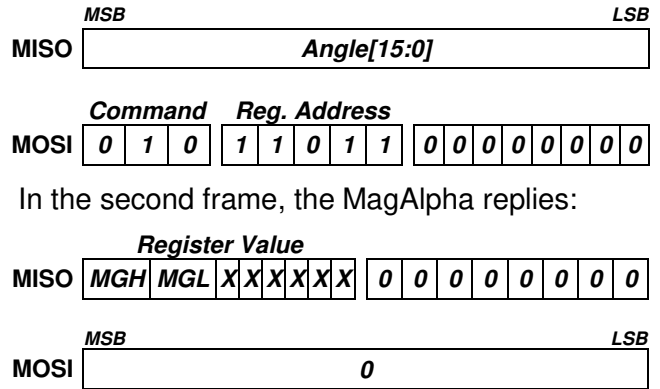

Figure 11 shows a complete transmission overview.

For example, to get the value of the magnetic level high and low flags (MGH and MGL), read register 27 (bit[6], bit[7]) by sending the following first frame:

In the second frame, the MagAlpha replies:

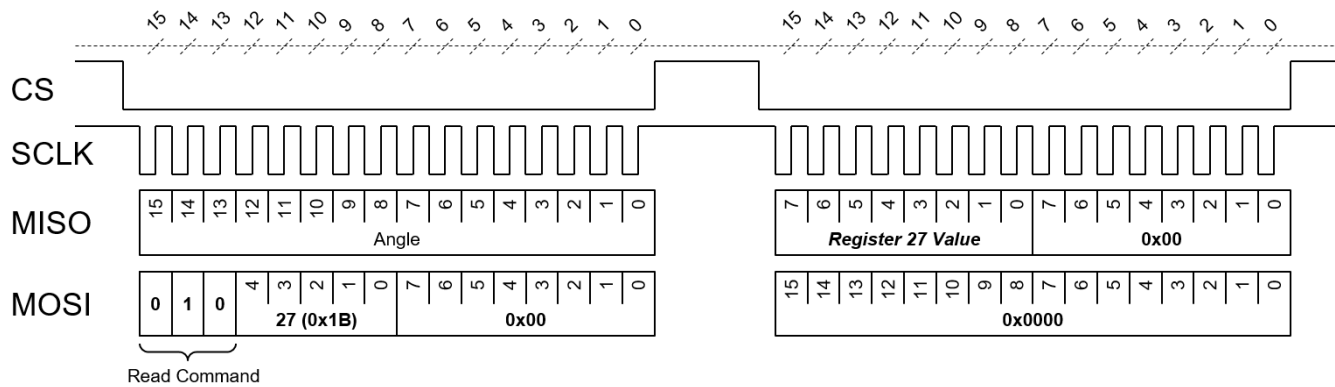

Figure 12 shows a complete example overview.

**Figure 11: Two 16-Bit Frames Read Register Operation**

**Figure 12: Example Read Magnetic Level Flags High and Low (MGH, MGH) on Register 27, Bits[6:7]**

**SPI Write Register**

The Register Map section on page 18 shows the programmable 8-bit registers. Data written to

these registers is stored in the on-chip non-volatile memory (NVM) and reloaded automatically at start-up.

A write register operation consists of two 16-bit frames. The first frame sends a write request, which contains the 3-bit write command (100), followed by the 5-bit register address and the 8-bit value (MSB first). The second frame returns the newly written register value (acknowledge).

The NVM is guaranteed to endure 1,000 write cycles at 25°C.

It is critical to wait 20ms between the first and the second frame. This is the time taken to write to the NVM. Failure to implement this wait period results in the register's previous value being read. Note that this delay is only required after a write request. A read register request or read angle does not require this wait time.

The first 16-bit SPI frame (write request) is:

The second 16-bit SPI frame (response) is:

The readback register content can be used to verify the register programming. Figure 13 shows a complete transmission overview.

For example, to set the value of the output rotation direction (RD) to counterclockwise (high), write register 9 by sending the following first frame:

Send the second frame after a 20ms wait time. If the register is written correctly, the reply is:

See Figure 14 for a complete example.

**Figure 13: Overview of Two 16-Bit Frames Write Register Operation**

**Figure 14: Example Write Output Rotation Direction (RD) to Counterclockwise (High), on Register 9, Bit 7**

### SSI

The SSI is a two-wire, synchronous serial interface for data reading only. The sensor operates as a slave to the external SSI master and only supports angle reading. It is not possible to read or write registers via the SSI.

### SSI Communication

Unlike the SPI, the sensor SSI only supports angle reading. It is not possible to read or write registers using the SSI. Figure 15 and Table 5 show the SSI timing communication details.

**Figure 15: SSI Timing**
**Table 5: SSI Timing**

Parameter	Description	Min	Max
$t_{SSD}$	Delay between the SCLK rising edge and the start of data transfer	-	15ns
$t_{SSCK}$	SCLK period	0.2 $\mu$ s	16 $\mu$ s
$t_{SSCKL}$	Low level of the SCLK signal	0.1 $\mu$ s	8 $\mu$ s
$t_{SSCKH}$	High level of the SCLK signal	0.1 $\mu$ s	8 $\mu$ s
$t_M$	Transfer timeout (monoflop time)	25 $\mu$ s	-
$t_P$	Dead time: SCLK high time for next data reading	40 $\mu$ s	-

### SSI Read Angle

The bit order of the transmitted data is MSB first and LSB last. Every 1 $\mu$ s, new data is transferred into the output buffer. The master device triggers the reading by driving SCLK high. A full reading requires up to 17 clock counts (see Figure 16).

The first clock is a dummy clock to start the transmission. The data length is up to 16 bits long. See the data output length section in the General Characteristics section on page 5 for the number of useful bits delivered at the serial output.

The first MSB are transmitted on the second clock count. If the data length is less than 16 bits, the 16-bit output word is completed by 0s. Therefore, the reading can also be performed with fewer than 16 clock counts. For example, for a part with a 12-bit data length, it is only necessary to send the first dummy clock to start the transmission + 12 clocks to read the angle data.

When a trigger event is detected, the data remains in the output buffer until the clock falling edge for the LSB bit = 0 and the transfer timeout time has passed (see Table 6).

**Table 6: Sensor Data Timing**

Trigger Event	Output Buffer Release
First SSCK pulse rising edge	SSCK falling edge + timeout $t_M$

**Figure 16: Diagram of a Full 16-Bit SSI Angle Reading (with First Dummy Clock)**

Figure 17 shows the timing for consecutive angle readings.

**Figure 17: Diagram of Two Consecutive 16-Bit SSI Angle Readings with the Required Dead Time between the Frames**

### Parity Bit

The parity bit, or check bit, is added to the output string to ensure that the total number of 1s in the string is even. It is used as error detecting code for angle or register reading. The MAQ473 transmits the parity bit at the 17th clock edge (see Table 7 and Figure 18).

**Table 7: Example of Parity Bit**

16-Bit Output	Number of Bits Set to 1	Output with the Parity Bit
0000000000000000	0	0000000000000000
1000110001100010	6	10001100011000100

Hysteresis	HYS	8	ABZ output hysteresis	21

## REGISTER SETTINGS

### Zero Setting

The MAQ473's zero position ( $a_0$ ) can be programmed with 16 bits of resolution. The angle streamed out by the MAQ473 ( $a_{OUT}$ ) is calculated with Equation (2):

$$a_{OUT} = a_{RAW} - a_0 \quad (2)$$

Where  $a_{RAW}$  is the raw angle provided by the MAQ473's front end.

The parameter  $Z[15:0]$ , which is 0 by default, is the complementary angle of the zero setting. In decimals, it can be calculated with Equation (3):

$$a_0 = 2^{16} - Z[15:0] \quad (3)$$

Table 11 shows the zero-setting parameter.

**Table 11: Zero-Setting Parameter**

Z[15:0]	Zero Position $a_0$ (16-Bit Decimal)	Zero Position $a_0$ (deg)
0	65536	360.000
1	65535	359.995
2	65534	359.989
...	...	...
65534	2	0.011
65535	1	0.005

### Example

To set the zero position to  $20^\circ$ , the  $Z[15:0]$  parameter must be equal to the complementary angle, and can be calculated with Equation (4):

$$Z[15:0] = 2^{16} - \frac{20^\circ}{360^\circ} 2^{16} = 61895 \quad (4)$$

In binary, it is written as 1111 0001 1100 0111.

Table 12 shows the content of registers 0 and 1.

**Table 12: Register 0 and 1 Content**

Reg	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
0	1	1	0	0	0	1	1	1
1	1	1	1	1	0	0	0	1

### Rotation Direction

By default, when looking at the top of the package, the angle increases when the magnetic field rotates clockwise (CW) (see Figure 19 and Table 13).

**Figure 19: Positive Rotation Direction of the Magnetic Field**

**Table 13: Rotation Direction Parameter**

RD	Positive Direction
0	Clockwise (CW)
1	Counterclockwise (CCW)

### BCT Settings (Bias Current Trimming)

#### Side-Shaft

When the MAQ473 is mounted on the side of the magnet, the relationship between the field angle and the mechanical angle is no longer directly linear. This effect is related to the fact that the tangential magnetic field is usually smaller than the radial field. Calculate the field ratio ( $k$ ) with Equation (5):

$$k = B_{RAD} / B_{TAN} \quad (5)$$

Where  $B_{RAD}$  and  $B_{TAN}$  are the maximum radial and tangential magnetic fields (see Figure 20).

**Figure 20: Side-Shaft Field**

The  $k$  ratio depends on the magnet geometry and the distance to the sensor. Having a  $k$  ratio different than 1 results in the sensor output response not being linear with respect to the mechanical angle. Note that the error curve has the shape of a double sinewave (see Figure 22 on page 21).  $E$  is the amplitude of this error.

The X-axis and Y-axis bias currents can be reduced by programming in order to recover an equal Hall signal for all angles, and therefore suppress the error. Parameter ETX and ETY control the direction in which sensitivity is reduced. The current reduction is set by the parameter bias current trimming register, BCT[7:0], which is an integer from 0 to 255.

In side-shaft configuration (i.e. the sensor center is located beyond the magnet’s outer diameter),  $k$  is greater than 1. For optimum compensation, the sensitivity of the radial axis should be reduced by setting the BCT parameter, calculated with Equation (6):

$$BCT[7 : 0] = 258 \left( 1 - \frac{1}{k} \right) \quad (6)$$

Figure 21 shows the optimum BCT value for a particular  $k$  ratio.

**Figure 21: Relation between the  $k$  Ratio and the Optimum BCT to Recover Linearity**

Table 14 shows some typical BCT values.

**Table 14: Example of BCT Settings**

E (deg)	Magnet Ratio $k$	BCT[7:0]
0	1.0	0
11.5	1.5	86
19.5	2.0	129
25.4	2.5	155
30.0	3.0	172
33.7	3.5	184
36.9	4.0	194
39.5	4.5	201
41.8	5.0	207

### Determining $k$ with the MagAlpha

It is possible to deduce the  $k$  ratio from the error curve obtained with the default BCT setting (BCT = 0). Rotate the magnet more than one revolution and record the output. Next, plot the error curve (the output minus the real mechanical position vs. the real mechanical position) and extract two parameters: the maximum error ( $E$ ) and the position of this maximum with respect to a zero crossing  $a_M$  (see Figure 22).  $k$  can be calculated with Equation (7):

$$k = \frac{\tan(E + a_M)}{\tan(a_M)} \quad (7)$$

**Figure 22: Error Curve in Side-Shaft Configuration with BCT = 0**

Table 14 provides some examples. Alternatively, the  $k$  parameter can be obtained using Figure 23.

**Figure 23: Relation between the Error Measured with BCT = 0 and the Magnet Ratio  $k$**

### Sensor Orientation

From the dot marked on the package, it is possible to know whether the radial field is aligned with sensor coordinate X or Y (see Figure 24).

**Figure 24: Package Top View with X- and Y-Axes**

Determine which axis needs to be reduced based on the qualitative field distribution around a ring (see Figure 20 on page 20). For example, with the arrangement shown in Figure 24, the field along the sensor Y direction is tangential and weaker, so the X-axis should be reduced (ETX = 1 and ETY = 0). If both ETX and ETY are set to 1, the current bias is reduced in both directions the same way (i.e. without side-shaft correction) (see Table 15).

**Table 15: Trimming Direction Parameters**

ETX	Enable Trimming of the X-Axis
0	Disabled
1	Enabled
ETY	Enable Trimming of the Y-Axis
0	Disabled
1	Enabled

### Magnetic Field Thresholds

The magnetic flags (MGL and MGH) indicate that the magnetic field at the sensor position is out of the range defined by the lower (MGLT) and upper magnetic field thresholds (MGHT) (see Figure 25).

**Figure 25: MGH and MGL Signals as a Function of the Field Strength**

MagHys, the typical hysteresis on the MGH and MGL signals, is 6mT. The MGLT and MGHT thresholds are coded on 3 bits and stored in register 6 (see Table 16).

**Table 16: Register 6**

Register 6							
Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
MGLT			MGHT			-	-

The 3-bit MGLT and MGHT values correspond to the magnetic field (see Table 17).

**Table 17: MGLT and MGHT: Binary to mT Relationship**

MGLT or MGHT <sup>(8)</sup>	Field Threshold in mT <sup>(7)</sup>	
	From Low to High Magnetic Field	From High to Low Magnetic Field
000	26	20
001	41	35
010	56	50
011	70	64
100	84	78
101	98	92
110	112	106
111	126	120

**Notes:**

- 7) Valid for  $V_{DD} = 3.3V$ . If different, then the field threshold is scaled by the factor  $V_{DD} / 3.3V$ .
- 8) MGLT can have a larger value than MGHT.

The MGL and MGH alarm flags are available to be read in register 27 (bit[6] and bit[7], respectively), and their logic state is also given at digital output pins 11 and 16.

To read the MGL and MGH flags via the SPI, send the 16-bit read command for register 27:

Command	Reg. Address	MSB	Value	LSB
0 1 0	1 1 0 1 1	0	0 0 0 0 0 0 0 0	0

The MAQ473 responds with the register 27 content in the next transmission:

Register 27 [7:0]							
MGH	MGL	x	x	MG1L	MG2L	x	x

The MGL and MGH flags' logic state has no effect on the angle output.

### MGL Application Note

Pulses with a duration of about 1.3 $\mu$ s to 1.5 $\mu$ s appear randomly in the MGL signal. They appear on both the pin and register values (Register 27, bit 6).

These pulses appear around angle values of 44, 138, 224, and 318 degrees (sensor output) or in an interval of  $\pm 1.5$  degrees around these values. These pulses have an amplitude of 3.3V (VDD). The minimum interval between two pulses is 100 $\mu$ s.

### MGL Workarounds

1. Invert the MGH signal to replace MGL. The MGL and MGH magnetic thresholds only differ by a small hysteresis (see Table 17 on page 22). An inverted MGH signal can be used to replace the MGL output in the application.
2. Read the MGL signal level twice. Using two readings, which must be between 2 $\mu$ s and 100 $\mu$ s apart, allows the user to distinguish erroneous from real transitions. Table 18 shows examples of different cases.
3. Read register 27 with the SPI and compute a corrected MGL value using MG1L and MG2L. The corrected MGL signal = not (MG1L OR MG2L). This means that the corrected MGL must be set to 1 only when both MG1L and MG2L are equal to 0. See the C implementation below:

```
correctedMGL = !(MG1L | MG2L)
```

**Table 18: MGL Multiple Reading Workaround**

	MGL First Reading	MGL Second Reading (e.g. 20 $\mu$ s After the First Reading)	True MGL Value
Case 1	0	Second reading is not needed	0
Case 2	1	1	1
Case 3	1	0	0

### Filter Window (FW)

The filter window (FW) affects the effective resolution (defined as the  $\pm 3\sigma$  noise interval) and the output bandwidth, which is characterized by  $f_{CUTOFF}$ .

Table 19 gives the resulting resolution and bandwidth for each window.

**Table 19: FW**

FW[7:0]	$\tau$ ( $\mu$ s)	Effective Resolution at 45mT (Bits)	$f_{CUTOFF}$ (Hz)	Start-Up Time (ms)
51	64	9.5	6000	0.5
68	128	10	3000	1.1
85	256	10.5	1500	2.5
102	512	11	740	5.5
119 (default)	1024	11.5	370	12
136	2048	12	185	26
153	4096	12.5	93	57
170	8192	13	46	123
187	16384	13.5	23	264

The time constant ( $\tau$ ) is the parameter entered in the transfer function (1). This allows the user to accurately model the system and analyze the stability of a control loop.

### ABZ Incremental Encoder Output

The MAQ473 ABZ output emulates a 12-bit incremental encoder (such as an optical encoder), providing logic pulses in quadrature (see Figure 26). Compared to signal A, signal B is shifted by a quarter of the pulse period. During one revolution, signal A pulses  $n$  times, where  $n$  is programmable from 1 to 1024 pulses per revolution. The number of pulses per channel per revolution is programmed by setting parameter PPT, which consists of 10 bits split between registers 0x4 and 0x5 (see Table 8 on page 18). The factory default value is 1023. Table 20 describes how to program PPT[9:0] to set the required resolution.

**Table 20: PPT**

PPT[9:0]	Pulses per Revolution	Edges per Revolution
0000000000	1 (min)	4 (min)
0000000001	2	8
0000000010	3	12
0000000011	4	16
...	...	...
1111111100	1021	4084
1111111101	1022	4088
1111111110	1023	4092
1111111111	1024 (max)	4096 (max)

For example, to set 120 pulses per revolution (i.e. 480 edges), set PPT to 120 - 1 = 119 (binary: 0001110111). Table 21 shows how to set registers 4 and 5.

**Table 21: Example PPT Setting for 120 Pulses**

	Bit[7]	Bit[6]	Bit[5]	Bit[4]	Bit[3]	Bit[2]	Bit[1]	Bit[0]
R4	1	1	0	0	0	0	0	0
R5	0	0	0	1	1	1	0	1

**Figure 26: ABZ Output Timing**

Signal Z (zero or index) rises only once per turn at the zero-angle position.

The position and length of the Z pulse is programmable via bits ILIP[3:0] in register 0x4 (see Figure 27).

**Figure 27: ILIP Parameter Effect on Index Shape**

By default, the ILIP parameter is 0000. The index rising edge is aligned with the channel B falling edge. The index length is half of the A or B pulse length, depending on the user's selection.

**ABZ Hysteresis**

The hysteresis is set by the parameter HYS (see Table 22 on page 24). To avoid spurious transitions (see Figure 28 on page 24), it is recommended that the hysteresis be 12 times greater than the output root mean square (RMS) noise ( $1\sigma$ ). Table 23 on page 24 shows indications of the  $1\sigma$  noise

**Table 22: HYS**

HYS[7:0]	Hysteresis (deg)
200	0.08
188	0.14
148	0.18
152	0.36
156 (default)	0.52
116	0.70
120	1.4
124	2.1
84	2.8

**Table 23: RMS Noise**

FW(7:0)	Effective Resolution at 45mT (Bits)	$1\sigma$ Noise (deg)
51	9.5	0.08
68	10	0.06
85	10.5	0.04
102	11	0.03
119 (default)	11.5	0.02
136	12	0.015
153	12.5	0.01
170	13	0.007
187	13.5	0.005

**Figure 28: Hysteresis of the Incremental Output**

**ABZ Jitter**

The ABZ state is updated at a frequency of 16MHz, enabling accurate operation up to a very high rpm (above  $10^5$ rpm).

The jitter characterizes how far a particular ABZ edge can occur at an angular position different from the ideal position (see Figure 29).

**Figure 29: ABZ Jitter**

The measurable jitter is composed by a systematic jitter (i.e. always the same deviation at a given angle, and given in the General Characteristics section on page 5) and a random jitter.

The random jitter reflects the sensor noise. Therefore, the edge distribution is the same as the SPI output noise. The random jitter is a function of the rotation speed. At lower speeds, the random jitter is less than the sensor noise.

This is a result of the fact that the probability of measuring an edge at a certain distance from the ideal position depends on the number of ABZ updates at this position.

### PWM Absolute Output

This output provides a logic signal with a duty cycle proportional to the angle of the magnetic field. For the PWM frequency ( $f_{PWM}$ ), see the General Characteristics section on page 5. The duty cycle is bound by a minimum value (1/514 of the period) and a maximum value (513/514 of the period), so it varies from 1/514 to 513/514 with a resolution of 14 bits (see Figure 30). The angle can be obtained by measuring the on time. Since the absolute  $f_{PWM}$  can vary from chip to chip or with the temperature, accurate angle detection requires measuring the duty cycle (i.e. measuring both the on time ( $t_{ON}$ ) and the off time ( $t_{OFF}$ )). The angle can be calculated with Equation (8):

$$\text{angle (in } ^\circ) = \frac{360}{512} \left( 514 \frac{t_{ON}}{t_{ON} + t_{OFF}} - 1 \right) \quad (8)$$

Figure 30 shows one period of the PWM signal. The period ( $t$ ) is  $1 / f_{PWM}$ .

**Figure 30: PWM Output Timing, Top Signal = 0°; Bottom Signal = Full Scale (i.e. 360° (1 - 1/16384))**

### Diagnostic Features

The following features can be used to determine correct operation:

1. Parity bit on the angle (see the Parity Bit section on page 16).
2. Magnetic field in range via MIR[3:0] (see below).

### Magnetic Field in Range

Bits MIR[3:0] in register 27 can be used to verify that the magnetic field is between the thresholds set by MGLT[2:0] and MGHT[2:0] in register 6. The value of MIR[3:0] is 0011 when the field is between these thresholds. This also indicates that the Hall sensor front end is functioning correctly and acquiring angle samples.

For example, assuming MGLT[2:0] is at its default value of 00 (15mT), and the MGHT[2:0] is at 111 (126mT), then if the field strength is between these values, the MIR[3:0] value is 0011.

Table 24 shows the MIR[3:0] values for the default threshold settings described above.

**Table 24: MIR[3:0] Logic States**

<b>MIR[3:0]</b>	<b>Conditions MGLT[2:0] at default 15mT, MGHT[2:0] at default 126mT</b>
0011	Field in range and Hall sensor array operational
1111	Field above MAGH and MAGL threshold (magnet too close to sensor)
0000	Field below MAGH and MAGL threshold (magnet too far away/missing)
0001	Invalid state: Hall array sensor functional error
0010	Invalid state: Hall array sensor functional error
0100	Invalid state: Hall array sensor functional error
1000	Invalid state: Hall array sensor functional error
1001	Invalid state: Hall array sensor functional error
1010	Invalid state: Hall array sensor functional error
1011	Invalid state: Hall array sensor functional error
1100	Invalid state: Hall array sensor functional error
1101	Invalid state: Hall array sensor functional error

## APPENDIX A: DEFINITIONS

<b>Effective Resolution (<math>3\sigma</math> noise level)</b>	The smallest angle increment distinguishable from the noise. The resolution is measured by computing three times $\sigma$ (the standard deviation in degrees) taken across 1,000 data points at a constant position. The resolution in bits is obtained with: $\log_2(360 / 6\sigma)$ .
<b>Refresh Rate</b>	The rate at which new data points are stored in the output buffer.
<b>ABZ Update Rate</b>	The rate at which a new ABZ state is computed. The inverse of this rate is the minimum time between two ABZ edges.
<b>Latency</b>	The time elapsed between the instant when the data is ready to be read and the instant at which the shaft passes that position. The lag in degrees is $\text{lag} = \text{latency} \times v$ , where $v$ is the angular velocity in deg/s.
<b>Start-Up Time</b>	The time until the sensor delivers valid data beginning at start-up.
<b>Integral Nonlinearity (INL)</b>	Maximum deviation between the average sensor output (at a fixed position) and the true mechanical angle (see Figure A1).

**Figure A1: Resolution, INL, Lag**

INL can be obtained from the error curve  $\text{err}(a) = \text{out}(a) - a$ , where  $\text{out}(a)$  is the average across 1,000 sensor outputs and  $a$  is the mechanical angle indicated by a high-precision encoder ( $<0.001^\circ$ ). INL is then calculated with Equation (A1):

$$\text{INL} = \frac{\max(\text{err}(a)) - \min(\text{err}(a))}{2} \tag{A1}$$

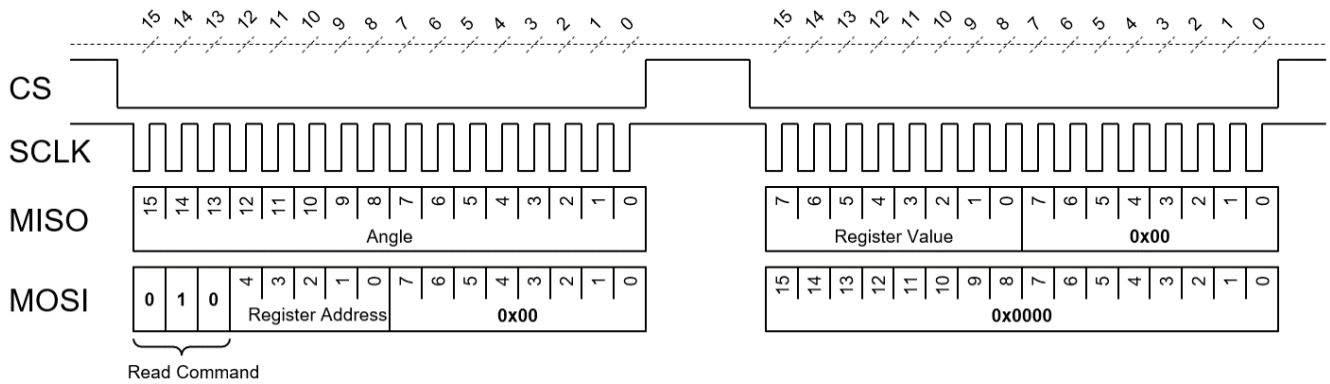

<b>Drift</b>	The angle variation rate when one parameter is changed (e.g. temperature, $V_{DD}$ ) but all others, including the shaft angle, remain constant.
