DESCRIPTION/ORDERING INFORMATION

This 1-bit to 4-bit address register/driver is designed for 1.65-V to 3.6-V V_{CC} operation. This device is ideal for use in applications in which a single address bus is driving four separate memory locations. The SN74ALVCH16832 can be used as a buffer or a register, depending on the logic level of the select ($\overline{SEL}$) input.

When $\overline{SEL}$ is a logic high, the device is in the buffer mode. The outputs follow the inputs and are controlled by the two output-enable ($\overline{OE}$) inputs. Each $\overline{OE}$ controls two groups of seven outputs.

When $\overline{SEL}$ is a logic low, the device is in the register mode. The register is an edge-triggered D-type flip-flop. On the positive transition of the clock (CLK) input, data at the A inputs is stored in the internal registers. $\overline{OE}$ operates the same as in the buffer mode.

When $\overline{OE}$ is a logic low, the outputs are in a normal logic state (high or low logic level). When $\overline{OE}$ is a logic high, the outputs are in the high-impedance state.

Neither $\overline{SEL}$ nor $\overline{OE}$ affect the internal operation of the flip-flops. Old data can be retained or new data can be entered while the outputs are in the high-impedance state.

DESCRIPTION/ORDERING INFORMATION (CONTINUED)

To ensure the high-impedance state during power up or power down, $\overline{OE}$ should be tied to V_{CC} through a pullup resistor; the minimum value of the resistor is determined by the current-sinking capability of the driver.

Active bus-hold circuitry holds unused or undriven inputs at a valid logic state. Use of pullup or pulldown resistors with the bus-hold circuitry is not recommended.
