

### 16-Bit Microcontrollers with Infrared Module and Optional USB

### General Description

The MAXQ612/MAXQ622 are low-power, 16-bit MAXQ® microcontrollers designed for low-power applications including universal remote controls, consumer electronics, and white goods. Both devices use a lowpower, high-throughput, 16-bit RISC microcontroller. Serial peripherals include two universal synchronous/ asynchronous receiver-transmitters (USARTs), two SPI™ master/slave communications ports, and an inter-integrated circuit (I2C) bus. The devices also incorporate an IR module with carrier frequency generation and flexible port I/O capable of multiplexed keypad control. The MAXQ622 adds a universal serial bus (USB) with integrated physical interface (PHY).

The MAXQ612/MAXQ622 include 128KB of flash memory and 6KB of data SRAM. Intellectual property (IP) protection is provided by a secure memory management unit (MMU) that supports multiple application privilege levels and protects code against copying and reverse engineering. Privilege levels enable vendors to provide libraries and applications to execute on the MAXQ612/MAXQ622, while limiting access to only data and code allowed by their privilege level.

For the ultimate in low-power battery-operated performance, the devices include an ultra-low-power stop mode (0.3µA typical). In this mode, the minimum amount of circuitry is powered. Wake-up sources include external interrupts, the power-fail interrupt, and a timer interrupt. The microcontroller runs from a wide operating voltage of 1.70V to 3.6V, and can also be powered from the USB.

 Active Mode *MAXQ is a registered trademark of Maxim Integrated Products, Inc. SPI is a trademark of Motorola, Inc.*

### Features

- ◆ High-Performance, Low-Power, 16-Bit RISC Core
- DC to 12MHz Operation Across Entire Operating Range
- ◆ 1.70V to 3.6V Operating Voltage
- Can Be Powered from Battery (VDD) or USB (VDDB)
- + 33 Total Instructions for Simplified Programming
- **+ Three Independent Data Pointers Accelerate Data** Movement with Automatic Increment/Decrement
- ◆ Dedicated Pointer for Direct Read from Code Space
- ◆ 16-Bit Instruction Word, 16-Bit Data Bus
- ◆ 16 x 16-Bit General-Purpose Working Registers
- ◆ Secure MMU for Application Partitioning and IP Protection
- ◆ Memory Features 128KB Flash Memory 512-Byte Sectors 20,000 Erase/Write Cycles per Sector 6KB Data SRAM
- ◆ USB Features (MAXQ622 Only) USB 2.0 Full-Speed Compatible Hardware Receive and Transmit Buffers for High **Throughput** Integrated Full-Speed Transceiver On-Chip Termination and Pullup Resistors
- **+ Additional Peripherals** Power-Fail Warning Power-On Reset (POR)/Brownout Reset Automatic IR Carrier Frequency Generation and Modulation Two 16-Bit Programmable Timers/Counters with Prescaler and Capture/Compare Two SPI Communication Ports Two USART Communication Ports I2C Port Programmable Watchdog Timer 8kHz Nanopower Ring Oscillator Wake-Up Timer Up to 56 General-Purpose I/O
- Low Power Consumption 0.3µA (typ), 3µA (max) in Stop Mode  $T_A = +25^\circ C$ , Power-Fail Monitor Disabled 4.8mA (typ) at 12MHz, 520µA (typ) at 1MHz in

*Note: Some revisions of this device may incorporate deviations from published specifications known as errata. Multiple revisions of any device*  may be simultaneously available through various sales channels. For information about device errata, go to: <www.maximintegrated.com/errata>.

For pricing, delivery, and ordering information, please contact Maxim Direct at 1-888-629-4642, or visit Maxim Integrated's website at www.maximintegrated.com.

### <span id="page-8-0"></span>I2C BUS CONTROLLER TIMING

(Notes 6, 21) (Figure 2)

**Note 1:** Specifications to  $0^{\circ}$ C are guaranteed by design and are not production tested.

- Note 2: VPFW can be programmed to the following nominal voltage trip points: 1.8V, 1.9V, 2.55V, and 2.75V  $\pm 3\%$ . The values listed in the *Recommended Operating Conditions* table are for the default configuration of 1.8V nominal.
- Note 3: It is not recommended to write to flash when the supply voltage drops below the power-fail warning levels, as there is uncertainty in the duration of continuous power supply. The user application should check the status of the power-fail warning flag before writing to flash to ensure complete write operations.
- Note 4: The power-fail warning monitor and the power-fail reset monitor are designed to track each other with a minimum delta between the two of 0.11V.
- Note 5: The power-fail reset and POR detectors are designed to operate in tandem to ensure that one or both of these signals is active at all times when  $V_{DD} < V_{RST}$ , ensuring the device maintains the reset state until minimum operating voltage is achieved.
- Note 6: Guaranteed by design and not production tested.
- Note 7: I<sub>S1</sub> is measured with the USB data RAM powered down.
- Note 8: The power-check interval (PCI) can be set to always on, or to 1024, 2048, or 4096 nanopower ring clock cycles.
- Note 9: Measured on the V<sub>DD</sub> pin and the device not in reset. All inputs are connected to GND or V<sub>DD</sub>. Outputs do not source/ sink any current. The device is executing code from flash memory.
- Note 10: Current consumption during POR when powering up while V<sub>DD</sub> is less than the POR release voltage.
- Note 11: The minimum amount of time that V<sub>DD</sub> must be below V<sub>PFW</sub> before a power-fail event is detected.
- Note 12: The maximum total current,  $I_{OH(MAX)}$  and  $I_{OL(MAX)}$ , for all listed outputs combined should not exceed 25mA to satisfy the maximum specified voltage drop. This does not include the IRTX output.
- Note 13: External clock frequency must be 12MHz to support USB functionality. Full-speed USB(12Mbps)-required bit-rate accuracy is  $\pm 2500$ ppm or  $\pm 0.25$ %. This is inclusive of all potential error sources: frequency tolerance, temperature, aging, crystal capacitive loading, board layout, etc.
- Note 14: Programming time does not include overhead associated with utility ROM interface.

## <span id="page-9-0"></span>16-Bit Microcontrollers with Infrared Module and Optional USB

Note 15: For USB operation, both V<sub>DD</sub> and V<sub>BUS</sub> must be connected.

- Note 16: FRCVDD is the force V<sub>DD</sub> power-supply bit (PWCN.10). When FRCVDD = 1, V<sub>DDB</sub> power switching is disabled, and V<sub>DD</sub> is always used as the core 3V power supply.
- Note 17: The ESD protection scheme is in production on existing parts. The  $1\mu$ F capacitor on VBUS is intended to protect that pin from ESD damage (rather than DP or DM) since it is externally exposed. The ESD test uses 150pF charged to 15kV applied to the  $1\mu$ F capacitor creating a delta V of approximately 2.25V and limiting the voltage on VBUS.
- Note 18: Devices that use nonstandard supply voltages that do not conform to the intended I<sup>2</sup>C bus system levels must relate their input levels to the voltage to which the pullup resistors Rp are connected.
- Note 19: The maximum fall time, tF\_I2C of 300ns for the SDA and SCL bus lines is longer than the specificed maximum to F\_I2C of 250ns for the output stages. This allows series protection resistors (RS) to be connected between the SDA/SCL pins and the SDA/SCL bus lines as shown in *I2C Bus Controller Timing* without exceeding the maximum specified fall time.
- **Note 20:**  $C_B$  = Capacitance of one bus line in  $pF$ .
- Note 21: All values referred to V<sub>IH I2C(MIN)</sub> and V<sub>IL\_I2C</sub> (MAX).
- Note 22: A device must internally provide a hold time of at least 300ns for the SDA signal (referred to the V<sub>IH</sub> I2C(MIN) of the SCL signal) to bridge the undefined region of the falling edge of SCL.
- Note 23: The maximum t<sub>HD:DAT</sub> need only be met if the device does not stretch the low period (t<sub>LOW I2C</sub>) of the SCL signal.
- Note 24: A fast-mode I<sup>2</sup>C bus device can be used in a standard-mode I<sup>2</sup>C bus system, but the requirement tSU:DAT  $\geq$  250ns must be met. This is automatically the case if the device does not stretch the low period of the SCL signal. If such a device does stretch the low period of the SCL signal, it must output the next data bit to the SDA line t<sub>R</sub>  $_{12C(MAX)} +$  tsu:DAT = 1000 + 250 = 1250ns (according to the standard-mode I2C specification) before the SCL line is released.
- Note 25: AC electrical specifications are guaranteed by design and are not production tested.

### Detailed Description

The MAXQ612/MAXQ622 provide integrated, low-cost solutions that simplify the design of IR communications equipment such as universal remote controls. Standard features include the highly optimized, single-cycle, MAXQ, 16-bit RISC core; 128KB of flash memory; 6KB data RAM; soft stack; 16 general-purpose registers; and three data pointers. The MAXQ core has the industry's best MIPS/mA rating, allowing developers to achieve the same performance as competing microcontrollers at substantially lower clock rates. Lower active-mode current combined with the even lower MAXQ612/MAXQ622 stop-mode current results in increased battery life. IR application-specific peripherals include flexible timers

for generating IR carrier frequencies and modulation. A high-current, 25mA, IR drive pin and output pins capable of sinking up to 5mA support IR applications. It also includes a USB slave interface compatible with existing host HID device drivers, I2C, dual SPI, dual USARTs, up to 56 general-purpose I/O pins ideal for keypad matrix input, and a power-fail-detection circuit to notify.

Operating from DC to 12MHz, almost all instructions execute in a single clock cycle (83.3ns at 12MHz), enabling nearly 12MIPS true-code operation. When active device operation is not required, an ultra-low-power stop mode can be invoked from software, resulting in quiescent current consumption of less than 300nA typical and 3µA maximum. The combination of high-performance instructions and ultra-low

## <span id="page-21-0"></span>16-Bit Microcontrollers with Infrared Module and Optional USB

stop-mode current increases battery life over competing microcontrollers. An integrated POR circuit with brownout support resets the device to a known condition following a power-up cycle or brownout condition. Additionally, a powerfail warning flag is set, and a power-fail interrupt can be generated when the system voltage falls below the powerfail warning voltage, VPFW. The power-fail warning feature allows the application to notify the user that the system supply is low and appropriate action should be taken.

#### Microprocessor

The MAXQ612/MAXQ622 are based on Maxim's MAXQ20 core, which is a low-power implementation of the new 16-bit MAXQ family of RISC cores. The core supports the Harvard memory architecture with separate internal 16-bit program and data address buses. A fixed 16-bit instruction word is standard, but data can be arranged in 8 or 16 bits. The MAXQ core is a pipelined processor with performance approaching 1MIPS per MHz. The 16-bit data path is implemented around register modules, and each register module contributes specific functions to the core. The accumulator module consists of sixteen 16-bit registers and is tightly coupled with the arithmetic logic unit (ALU). Program flow is supported by a configurable soft stack.

Execution of instructions is triggered by data transfer between functional register modules or between a functional register module and memory. Because data movement involves only source and destination modules, circuit switching activities are limited to active modules only. For power-conscious applications, this approach localizes power dissipation and minimizes switching noise. The modular architecture also provides a maximum of flexibility and reusability that are important for a microprocessor used in embedded applications.

The MAXQ instruction set is highly orthogonal. All arithmetical and logical operations can use any register in conjunction with the accumulator. Data movement is supported from any register to any other register. Memory is accessed through specific data-pointer registers with autoincrement/decrement support.

#### Memory

The microcontroller incorporates several memory types:

- 128KB program flash memory
- 6KB SRAM data memory
- 6KB utility ROM
- Soft stack

#### Memory Protection

The optional memory-protection feature separates code memory into three areas: system, user loader, and user application. Code in the system area can be kept confidential. Code in the user areas can be prevented from reading and writing system code. The user loader can also be protected from user application code.

Memory protection is implemented using privilege levels for code. Each area has an associated privilege level. RAM/ROM are assigned privilege levels as well. Refer to the *MAXQ622 User's Guide* for a more thorough explanation of the topic.

#### Stack Memory

A 16-bit-wide internal stack provides storage for program return addresses and can also be used for generalpurpose data storage. The stack is used automatically by the processor when the CALL, RET, and RETI instructions are executed and when an interrupt is serviced. An application can also store values in the stack explicitly by using the PUSH, POP, and POPI instructions.

On reset, the stack pointer, SP, initializes to the top of the stack (BF0h). The CALL, PUSH, and interrupt-vectoring operations decrement SP, then store a value at the location pointed to by SP. The RET, RETI, POP, and POPI operations retrieve the value at SP and then increment SP.

#### Utility ROM

The utility ROM is a 6KB block of internal ROM memory that defaults to a starting address of 8000h. The utility

Watchdog Timer

### 16-Bit Microcontrollers with Infrared Module and Optional USB

<span id="page-22-0"></span>ROM consists of subroutines that can be called from application software. These include the following:

- In-system programming (bootstrap loader) using JTAG interface
- In-circuit debug routines
- Test routines (internal memory tests, memory loader, etc.)
- User-callable routines for in-application flash memory programming and fast table lookup

Following any reset, execution begins in the utility ROM. The ROM software determines whether the program execution should immediately jump to location 0000h, the start of system code, or to one of the special routines mentioned. Routines within the utility ROM are user accessible and can be called as subroutines by the application software. More information on the utility ROM functions is contained in the *MAXQ622 User's Guide*.

Some applications require protection against unauthorized viewing of program code memory. For these applications, access to in-system programming, inapplication programming, or in-circuit debugging functions is prohibited until a password has been supplied. The password is defined as the 16 words of physical program memory at addresses 0010h to 001Fh.

Three password locks protect three different program memory segments. When the PWL is set to one (poweron reset default) and the contents of the memory at addresses 0010h to 001Fh are any value other than FFh or 00h, the password is required to access the utility ROM, including in-circuit debug and in-system programming routines that allow reading or writing of internal memory. When PWL is cleared to zero, these utilities are fully accessible without password. The PWLS bit uses a password that is at ULDR + 0010 to ULDR + 001F, and the PWLL uses a password at UAPP  $+$  0010 to UAPP  $+$ 001F. The password is automatically set to all ones following a mass erase.

The internal watchdog timer greatly increases system reliability. The timer resets the device if software execution is disturbed. The watchdog timer is a free-running counter designed to be periodically reset by the application software. If software is operating correctly, the counter is periodically reset and never reaches its maximum count. However, if software operation is interrupted, the timer does not reset, triggering a system reset and optionally a watchdog timer interrupt. This protects the system against electrical noise or electrostatic discharge (ESD) upsets that could cause uncontrolled processor operation. The internal watchdog timer is an upgrade to older designs with external watchdog devices, reducing system cost and simultaneously increasing reliability.

The watchdog timer functions as the source of both the watchdog timer timeout and the watchdog timer reset. The timeout period can be programmed in a range of 215 to 224 system clock cycles. An interrupt is generated when the timeout period expires if the interrupt is enabled. All watchdog timer resets follow the programmed interrupt timeouts by 512 system clock cycles. If the watchdog timer is not restarted for another full interval in this time period, a system reset occurs when the reset timeout expires.

### IR Carrier Generation and Modulation Timer

The dedicated IR timer/counter module simplifies lowspeed infrared (IR) communication. The IR timer implements two pins (IRTX and IRRX) for supporting IR transmit and receive, respectively. The IRTX pin has no corresponding port pin designation, so the standard PD, PO, and PI port control status bits are not present. However, the IRTX pin output can be manipulated high or low using the PWCN.IRTXOUT and PWCN.IRTXOE bits when the IR timer is not enabled (i.e., IREN =  $0$ ).

Table 2. Watchdog Interrupt Timeout (Sysclk = 12MHz, CD[1:0] = 00)

<b>WD[1:0]</b>	<b>WATCHDOG CLOCK</b>	<b>WATCHDOG INTERRUPT TIMEOUT</b>	<b>WATCHDOG RESET AFTER</b> <b>WATCHDOG INTERRUPT (µs)</b>
00	Sysclk/215	2.7ms	42.7
01	Sysclk/218	21.9ms	42.7
10	Sysclk/2 <sup>21</sup>	174.7ms	42.7
	Sysclk/224	1.4s	42.7

## <span id="page-23-0"></span>16-Bit Microcontrollers with Infrared Module and Optional USB

The IR timer is composed of a carrier generator and a carrier modulator. The carrier generation module uses the 16-bit IR carrier register (IRCA) to define the high and low time of the carrier through the IR carrier high byte (IRCAH) and IR carrier low byte (IRCAL). The carrier modulator uses the IR data bit (IRDATA) and IR modulator time register (IRMT) to determine whether the carrier or the idle condition is present on IRTX.

#### Carrier Generation Module

The IRCAH byte defines the carrier high time in terms of the number of IR input clocks, whereas the IRCAL byte defines the carrier low time.

- IR Input Clock  $(f|RCLK) = fSYS/2|RDIV[1:0]$
- Carrier Frequency (fCARRIER) = fIRCLK/(IRCAH +  $IRCAL + 2)$
- Carrier High Time =  $IRCAH + 1$
- Carrier Low Time = IRCAL + 1
- Carrier Duty Cycle = (IRCAH + 1)/(IRCAH + IRCAL + 2)

During transmission, the IRCA register is latched for each IRV downcount interval, and is sampled along with the IRTXPOL and IRDATA bits at the beginning of each new IRV downcount interval so that duty-cycle variation and frequency shifting is possible from one interval to the next. The starting/idle state and the carrier polarity of the IRTX pin can be configured when the IR timer is enabled.

IR Transmission

During IR transmission (IRMODE = 1), the carrier generator creates the appropriate carrier waveform, while the carrier modulator performs the modulation. The carrier modulation can be performed as a function of carrier cycles or IRCLK cycles dependent on the setting of the IRCFME bit. When IRCFME  $= 0$ , the IRV down counter is clocked by the carrier frequency and thus the modulation is a function of carrier cycles. When IRCFME = 1, the IRV down counter is clocked by IRCLK, allowing carrier modulation timing with IRCLK resolution.

The IRTXPOL bit defines the starting/idle state as well as the carrier polarity for the IRTX pin. If IRTXPOL  $= 1$ , the IRTX pin is set to a logic-high when the IR timer module is enabled. If  $IRTXPOL = 0$ , the  $IRTX$  pin is set to a logic-low when the IR timer is enabled.

A separate register bit, IR data (IRDATA), is used to determine whether the carrier generator output is output to the IRTX pin for the next IRMT carrier cycles. When IRDATA  $= 1$ , the carrier waveform (or inversion of this waveform if  $IRTXPOL = 1$ ) is output on the IRTX pin during the next IRMT cycles. When IRDATA  $= 0$ , the idle condition, as defined by IRTXPOL, is output on the IRTX pin during the next IRMT cycles.

The IR timer acts as a down counter in transmit mode. An IR transmission starts when the IREN bit is set to 1 when  $IMODE = 1$ ; when the IRMODE bit is set to 1 when IREN  $= 1$ ; or when IREN and IRMODE are both set to 1 in the same instruction. The IRMT and IRCA registers, along with the IRDATA and IRTXPOL bits, are sampled at the beginning of the transmit process and every time the IR timer value reload its value. When the IRV reaches 0000h value, on the next carrier clock, it does the following:

- 1) Reloads IRV with IRMT.
- 2) Samples IRCA, IRDATA, and IRTXPOL.
- 3) Generates IRTX accordingly.
- 4) Sets IRIF to 1.
- 5) Generates an interrupt to the CPU if enabled (IRIE  $= 1$ ).

#### IR Transmit—Independent External Carrier and Modulator Outputs

The normal transmit mode modulates the carrier based upon the IRDATA bit. However, the user has the option to input the modulator (envelope) on an external pin if desired. The IRDATA bit is output directly to the IRTXM pin (if IRTXPOL = 0) on each IRV downcount interval boundary just as if it were being used to internally modulate the carrier frequency. If  $IRTXPOL = 1$ , the inverse of the IRDATA bit is output to the IRTXM pin on the IRV interval downcount boundaries. When the envelope mode is enabled, it is possible to output either the modulated (IRENV[1:0] = 01b) or unmodulated (INENV[1:0] = 10b) carrier to the IRTX pin.

#### IR Receive

When configured in receive mode (IRMODE =  $0$ ), the IR hardware supports the IRRX capture function. The IRRXSEL[1:0] bits define which edge(s) of the IRRX pin should trigger the IR timer capture function. Once started, the IR timer (IRV) starts up counting from 0000h when a qualified capture event as defined by IRRXSEL happens. The IRV register is, by default, counting carrier cycles as defined by the IRCA register. However, the IR carrier frequency detect (IRCFME) allows clocking of the IRV register directly with the IRCLK for finer resolution. When IRCFME = 0, the IRCA defined carrier is counted by IRV. When IRCFME = 1, the IRCLK clocks the IRV register.

On the next qualified event, it does the following:

1) Captures the IRRX pin state and transfers its value to IRDATA. If a falling edge occurs, IRDATA  $= 0$ . If a rising edge occurs, IRDATA = 1.

## 16-Bit Microcontrollers with Infrared Module and Optional USB

- <span id="page-24-0"></span>2) Transfers its current IRV value to the IRMT.
- 3) Resets IRV content to 0000h (if IRXRL = 1).
- 4) Continues counting again until the next qualified event.

If the IR timer value rolls over from 0FFFFh to 0000h before a qualified event happens, the IR timer overflow (IROV) flag is set to 1 and an interrupt is generated, if enabled. The IR module continues to operate in receive mode until it is stopped by switching into transmit mode or clearing  $IREN = 0$ .

### Carrier Burst-Count Mode

A special mode reduces the CPU processing burden when performing IR learning functions. Typically, when operating in an IR learning capacity, some number of carrier cycles are examined for frequency determination. Once the frequency has been determined, the IR receive function can be reduced to counting the number of carrier pulses in the burst and the duration of the combined mark-space time within the burst. To simplify this process, the receive burst-count mode can be used. When  $RXBCNT = 0$ , the standard IR receive capture functionality is in place. When  $RXBCNT = 1$ , the IRV capture operation is disabled and the interrupt flag associated with the capture no longer denotes a capture. In the carrier burst-count mode, the IRMT register only counts qualified edges. The IRIF interrupt flag now sets if two IRCA cycles elapse without getting a qualified edge. The IRIF interrupt flag thus denotes absence of the carrier and the beginning of a space in the receive signal. The IRCFME bit is still used to define whether the IRV register is counting system IRCLK clocks or IRCA-defined carrier cycles. The IRXRL bit defines whether the IRV register is reloaded with 0000h on detection of a qualified edge (per the IRXSEL[1:0] bits).

### 16-Bit Timers/Counters

The microcontroller provides two general-purpose timers/counters that support the following functions:

- 16-bit timer/counter
- 16-bit up/down autoreload
- Counter function of external pulse
- 16-bit timer with capture
- 16-bit timer with compare
- Input/output enhancements for pulse-width modulation
- Set/reset/toggle output state on comparator match
- Prescaler with 2n divider (for  $n = 0, 2, 4, 6, 8, 10$ )

### General-Purpose I/O

The microcontroller provides port pins for general-purpose I/O that have the following features:

- CMOS output drivers
- Schmitt trigger inputs
- Optional weak pullup to V<sub>DD</sub> when operating in input mode

While the microcontroller is in a reset state, all port pins become three-state with both weak pullups and input buffers disabled, unless otherwise noted.

From a software perspective, each port appears as a group of peripheral registers with unique addresses. Special function pins can also be used as general-purpose I/O pins when the special functions are disabled. For a detailed description of the special functions available for each pin, refer to the IC-specific user's guide, e.g., the *MAXQ622 User's Guide* describes all special functions available on the MAXQ612/MAXQ622.

### Serial Peripherals

The microcontroller supports two independent USARTs, two SPI master/slave communications ports, and an I2C bus.

### USART

The USART units are implemented with the following characteristics:

- 2-wire interface
- Full-duplex operation for asynchronous data transfers
- Half-duplex operation for synchronous data transfers
- Programmable interrupt for receive and transmit
- Independent baud-rate generator

### Table 3. USART Mode Details

## <span id="page-25-0"></span>16-Bit Microcontrollers with Infrared Module and Optional USB

I2C Bus

- Programmable 9th bit parity support
- Start/stop bit support

#### Serial Peripheral Interface (SPI)

The dual-integrated SPI interfaces provide independent serial communication channels that communicate synchronously with peripheral devices in a multiple master or multiple slave system. The interface allows access to a 4-wire, full-duplex serial bus, and can be operated in either master mode or slave mode. Collision detection is provided when two or more masters attempt a data transfer at the same time.

The maximum SPI master transfer rate is Sysclk/2. When operating as an SPI slave, the MAXQ612/MAXQ622 can support up to Sysclk/4 SPI transfer rate. Data is transferred as an 8-bit or 16-bit value, MSB first. In addition, the SPI module supports configuration of an active SSEL state through the slave active select. Separate pins and registers are used to differentiate between the two SPI ports.

The microcontroller integrates an internal I2C bus master/slave for communication with a wide variety of other I2C–enabled peripherals. The I2C bus is a 2-wire, bidirectional bus using two bus lines—the serial data line (SDA) and the serial clock line (SCL)—and a ground line. Both the SDA and SDL lines must be driven as opencollector/drain outputs. External resistors are required as shown in Figure 1 to pull the lines to a logic-high state.

The device supports both the master and slave protocols. In the master mode, the device has ownership of the I2C bus, drives the clock, and generates the START and STOP signals. This allows it to send data to a slave or receive data from a slave as required. In slave mode, the device relies on an externally generated clock to drive SCL and responds to data and commands only when requested by the I<sup>2</sup>C master device.

### USB Controller (MAXQ622 Only)

The integrated USB controller is compliant with the USB 2.0 specification, providing full-speed operation with the newest generation of USB peripherals. The USB controller functions as a full-speed USB peripheral device. Integrating the USB physical interface (PHY) allows direct connection to the USB cable, reducing board space and overall system cost. A system interrupt can be enabled to signal that the USB needs to be serviced. The CPU communicates to the USB controller module through the SFR interface. The microcontroller is seen by a USB host as a peripheral, characterized by the following endpoints:

- EP0: Bidirectional CONTROL endpoint with a 64-byte data storage.
- EP1-OUT: BULK (or INT) OUT endpoint. Doublebuffered 64 bytes data storage.
- EP2-IN: BULK (or INT) IN endpoint. Double-buffered 64 bytes data storage.
- EP3-IN: BULK (or INT) IN endpoint. Single-buffered 64 bytes data storage.

The choice to use EP1, EP2, and EP3 as BULK or INTERRUPT endpoints is strictly a function of the endpoint descriptors that the USB controller returns to the USB host during enumeration.

The USB controller communicates to a total of 384 bytes of endpoint data memory (2 x 64 bytes for each data moving endpoint EP1 and EP2), 64 bytes for the CONTROL endpoint, and 64 bytes for endpoint EP3.

Double-buffering EP1 and EP2 improves throughput by allowing the CPU to read or load the next packet while the USB controller is moving the current packet over USB. EP3-IN is intended to serve as a large interrupt endpoint for various USB class specifications such as the Still Image Capture Device. It can also be used as a second BULK IN endpoint.

### On-Chip Oscillator

An external quartz crystal or a ceramic resonator can be connected between HFXIN and HFXOUT, as illustrated in Figure 3.

To operate the core from an external clock, connect the clock source to the HFXIN pin and connect the HFXOUT

*Figure 3. On-Chip Oscillator*

26 Maxim Integrated 20 Maxim Integrated 20 Maxim Integrated 20 Maxim Integrated 20

### 16-Bit Microcontrollers with Infrared Module and Optional USB

<span id="page-26-0"></span>pin to GND. The clock source should be driven through a CMOS driver. If the clock driver is a TTL gate, its output must be connected to V<sub>DD</sub> through a pullup resistor to ensure a satisfactory logic level for active clock pulses. To minimize system noise on the clock circuitry, the external clock source must meet the maximum rise and fall times and the minimum high and low times specified for the clock source. The external noise can affect the clock generation circuit if these parameters do not meet the specification.

Noise at HFXIN and HFXOUT can adversely affect onchip clock timing. It is good design practice to place the crystal and capacitors as near the oscillator circuitry as possible with a direct short trace. The typical values of external capacitors vary with the type of crystal to be used.

### ROM Loader

The ROM loader loads program memory and configures loader-specific configuration features. To increase the security of the system, the loader denies access to the system, user loader, or user-application memories unless an area-specific password is provided.

### Loading Flash Memory

An internal bootstrap loader allows reloading over a simple JTAG interface. As a result, software can be upgraded in-system, eliminating the need for a costly hardware retrofit when updates are required. Remote software uploads are possible that enable physically inaccessible applications to be frequently updated. The interface hardware can be a JTAG connection to another microcontroller, or a connection to a PC serial port using a USB-to-JTAG converter such as the MAXQUSBJTAG-KIT#, available from Maxim. If in-system programmability is not required, a commercial gang programmer can be used for mass programming. Activating the JTAG interface and loading the test access port (TAP) with the system programming instruction invokes the bootstrap loader. Setting the SPE bit to one during reset through the JTAG interface executes the bootstrap-loader mode program that resides in the utility ROM. When programming is complete, the bootstrap loader can clear the SPE bit and reset the device, allowing the device to bypass the utility ROM and begin execution of the application software.

In addition, the ROM loader also enforces the memoryprotection policies. Passwords that are 16 words are required to access the ROM loader interface.

### In-Application Flash Programming

From user-application code, flash memory can be programmed using the ROM utility functions from either C or assembly language. The function declarations below show examples of some of the ROM utility functions provided for in-application flash memory programming:

/\* Write one 16-bit word to code address 'dest'.

- \* Dest must be aligned to 16 bits.
- \* Returns  $0 = \text{failure}, 1 = \text{OK}.$

\*/

int flash write (uint16 t dest, uint16 t data); To erase, the following function would be used:

/\* Erase the given Flash page

\* addr: Flash offset (anywhere within page) \*/

int flash erasepage(uint16 t addr);

The in-application flash memory programming must call ROM utility functions to erase and program any of the flash memory. Memory protection is enforced by the ROM utility functions.

### In-Circuit Debug and JTAG **Interface**

Embedded debug hardware and software are developed and integrated to provide full in-circuit debugging capability in a user-application environment. These hardware and software features include the following:

- Debug engine
- Set of registers providing the ability to set breakpoints on register, code, or data using debug service routines stored in ROM

Collectively, these hardware and software features support two modes of in-circuit debug functionality:

• Background mode:

CPU is executing the normal user program

 Allows the host to configure and set up the in-circuit debugger

• Debug mode:

Debugger takes over the control of the CPU

 Read/write accesses to internal registers and memory Single-step of the CPU for trace operation

The interface to the debug engine is the TAP controller. The interface allows for communication with a bus

## <span id="page-27-0"></span>16-Bit Microcontrollers with Infrared Module and Optional USB

*Figure 4. In-Circuit Debugger*

master that can either be automatic test equipment or a component that interfaces to a higher level test bus as part of a complete system. The communication operates across a 4-wire serial interface from a dedicated TAP that is compatible with the JTAG IEEE Standard 1149. The TAP provides an independent serial channel to communicate synchronously with the host system.

To prevent unauthorized access of the protected memory regions through the JTAG interface, the debug engine prevents modification of the privilege registers and disallows all access to system memory, unless memory protection is disabled. In addition, all services (such as register display or modification) are denied when code is executing inside the system area.

### Operating Modes

#### Power-Supply Selection

For maximum flexibility the microcontroller can be powered by either the USB (VBUS) or VDD. When a USB connection is made to a valid VBUS power source, an internal voltage regulator generates a 3.3V supply voltage. When the internal voltage is at an adequate level, it automatically powers itself from the USB supply. This is especially beneficial in systems where the V<sub>DD</sub> supply is from a battery. In either case, the chip is fully functional when operating from either the battery or the VBUS.

The power monitor is attached to the switched supply, V<sub>DDIO</sub>. This supply is equivalent to the higher of V<sub>DDB</sub> or V<sub>DD</sub>. This can be expressed as follows:

If  $(V_{\text{DDB}} > 3.0V$  or  $V_{\text{DDB}} > V_{\text{DD}}$ 

then  $(VDDIO = VDDB)$ else (VDDIO = VDD)

This means that if there is a power-fail event on V<sub>DD</sub> and the device is not powered from VBUS, it causes a powerfail interrupt (PFI) if enabled. If the device is powered by VBUS and there is a supply on VDD, then no power-fail event is triggered. If the device is powered by VBUS and there is no supply on  $V_{DD}$  and  $V_{BUS}$  fails, the chip attempts to switch to VDD, detects a power-fail event, and a PFI occurs. Some specific examples are given below:

- Case 1: The device is powered from V<sub>DD</sub> and the batteries are removed. Power decays until the power-fail-reset trip point is hit, then the part goes into low-power mode.
- Case 2: The device is set to be powered from VDD only, it is connected to USB, and the batteries are removed. Response is identical to Case 1.
- Case 3: The device is set to be powered from either VDD or VBUS, it is connected to USB, and the batteries are removed. Because the part is already powered from VBUS, nothing changes. If the USB port is subsequently disconnected, power switches over to VDD, the supply decays to the power-fail-reset trip point, and the part goes into low-power mode. As long as there is sufficient charge on the V<sub>DD</sub> bypass capacitor, it supports the part in power-fail. The holdup time is similar to the MAXQ610 since the USB port is powered only by VBUS. Note that if the part is powered from VBUS and no battery has been present for a long time ( $V_{DD} = 0$ ), then upon USB port disconnection, the power collapses to ground in less than a second.

#### Stop Mode

The lowest power mode of operation is stop mode. In this mode, CPU state and memories are preserved, but the CPU is not actively running. Wake-up sources include external I/O interrupts, the power-fail warning interrupt, wake-up timer, or a power-fail reset. Any time the microcontroller is in a state where code does not need to be executed, the user software can put the microcontroller into stop mode. The nanopower ring oscillator is an internal ultra-low-power (400nA) 8kHz ring oscillator that can be used to drive a wake-up timer that exits stop mode. The wake-up timer is programmable by software in steps of 125µs up to approximately 8s.

The power-fail monitor is always on during normal operation. However, it can be selectively disabled during stop

## 16-Bit Microcontrollers with Infrared Module and Optional USB

#### <span id="page-28-0"></span>Table 4. Power-Fail Warning Level Selection

mode to minimize power consumption. This feature is enabled using the power-fail monitor disable (PFD) bit in the PWCN register. The reset default state for the PFD bit is 1, which disables the power-fail monitor function during stop mode. If power-fail monitoring is disabled  $(PFD = 1)$  during stop mode, the circuitry responsible for generating a power-fail warning or reset is shut down and neither condition is detected. Thus, the  $VDD < VRST$ condition does not invoke a reset state. However, in the event that V<sub>DD</sub> falls below the POR level, a POR is generated. The power-fail monitor is enabled prior to stop mode exit and before code execution begins. If a powerfail warning condition ( $V_{\text{DD}}$  <  $V_{\text{PFW}}$ ) is then detected, the power-fail interrupt flag is set on stop mode exit. If a power-fail reset condition is detected ( $V_{DD}$  <  $V_{RST}$ ), the CPU goes into reset.

#### Power-Fail Warning

The power-fail monitor can assert an interrupt if the voltage falls below a configurable threshold between the operating voltage and the reset voltage. This, if enabled, can allow the firmware to perform housekeeping tasks if the voltage level decays below the warning threshold. The power-fail threshold value should only be changed when the power-fail warning interrupt is disabled (CKCN.  $PFIE = 0$ ) to prevent unintended triggering of the powerfail warning condition.

The power-fail warning threshold is reset to 1.8V by a POR and is not affected by other resets. See Table 4.

#### Power-Fail Detection

Figures 5, 6, and 7 show the power-fail detection and response during normal and stop-mode operation.

If a reset is caused by a power-fail, the power-fail monitor can be set to one of the following intervals:

- Always on—continuous monitoring
- 2<sup>11</sup> nanopower ring oscillator clocks (~256ms)
- 2<sup>12</sup> nanopower ring oscillator clocks (~512ms)
- 2<sup>13</sup> nanopower ring oscillator clocks  $(-1.024s)$

In the case where the power-fail circuitry is periodically turned on, the power-fail detection is turned on for two

*Figure 5. Power-Fail Detection During Normal Operation*

### <span id="page-29-0"></span>16-Bit Microcontrollers with Infrared Module and Optional USB

### Table 5. Power-Fail Detection States During Normal Operation

nanopower ring-oscillator cycles. If VDD > VRST during detection, V<sub>DD</sub> is monitored for an additional nanopower ring-oscillator period. If V<sub>DD</sub> remains above VRST for the third nanopower ring period, the CPU exits the reset state and resumes normal operation from utility ROM at 8000h after satisfying the crystal warmup period.

If a reset is generated by any other event, such as the RESET pin being driven low externally or the watchdog timer, the power-fail, internal regulator, and crystal remain on during the CPU reset. In these cases, the CPU exits the reset state in less than 20 crystal cycles after the reset source is removed.

<b>STATE</b>	<b>POWER-FAIL</b>	<b>INTERNAL</b> <b>REGULATOR</b>	<b>CRYSTAL</b> <b>OSCILLATOR</b>	<b>SRAM</b> <b>RETENTION</b>	<b>COMMENTS</b>
D	Off	Off	Off	Yes	Application enters stop mode. V <sub>DD</sub> > V <sub>RST</sub> CPU in stop mode.
F	On (Periodically)	Off	Off	Yes	$VPOR < VDD < VRST$ . An interrupt occurs that causes the CPU to exit stop mode. Power-fail monitor is turned on, detects a power-fail, and puts CPU in reset. Power-fail monitor is turned on periodically.
F	Off	Off	Off		VDD < VPOP. Device held in reset. No operation allowed.

### Applications Information

The low-power, high-performance RISC architecture of this device makes it an excellent fit for many portable or battery-powered applications. It is ideally suited for applications such as universal remote controls that require the cost-effective integration of IR transmit/ receive capability.

#### Grounds and Bypassing

Careful PCB layout significantly minimizes system-level digital noise that could interact with the microcontroller or peripheral components. The use of multilayer boards is essential to allow the use of dedicated power planes. The area under any digital components should be a continuous ground plane if possible. Keep bypass capacitor leads short for best noise rejection and place the capacitors as close to the leads of the devices as possible.

CMOS design guidelines for any semiconductor require that no pin be taken above VDD or below GND. Violation of this guideline can result in a hard failure (damage to the silicon inside the device) or a soft failure (unintentional modification of memory contents). Voltage spikes above or below the device's absolute maximum ratings can potentially cause a devastating IC latchup.

Microcontrollers commonly experience negative voltage spikes through either their power pins or general-

purpose I/O pins. Negative voltage spikes on power pins are especially problematic as they directly couple to the internal power buses. Devices such as keypads can conduct electrostatic discharges directly into the microcontroller and seriously damage the device. System designers must protect components against these transients that can corrupt system memory.

### Additional Documentation

Designers must have the following documents to fully use all the features of this device. This data sheet contains pin descriptions, feature overviews, and electrical specifications. Errata sheets contain deviations from published specifications. The user's guides offer detailed information about device features and operation. The following documents can be downloaded from <www.maximintegrated.com/microcontrollers>.

- This MAXQ612/MAXQ622 data sheet, which contains electrical/timing specifications and pin descriptions.
- The MAXQ612 /MAXQ622 revision-specific errata sheet (<www.maximintegrated.com/errata>).
- The *MAXQ622 User's Guide*, which contains detailed information on features and operation, including programming.

### Development and Technical Support

Maxim and third-party suppliers provide a variety of highly versatile, affordably priced development tools for this microcontroller, including the following:

- Compilers
- In-circuit emulators
- Integrated Development Environments (IDEs)
- JTAG-to-serial converters for programming and debugging

A partial list of development tool vendors can be found at [www.maximintegrated.com/MAXQ\\_tools](www.maximintegrated.com/MAXQ_tools).

<span id="page-33-0"></span>For technical support, go to **[https://support.maximinte](https://support.maximintegrated.com/micro)**[grated.com/micro](https://support.maximintegrated.com/micro).

### Package Information

For the latest package outline information and land patterns (footprints), go to <www.maximintegrated.com/packages>. Note that a "+", "#", or "-" in the package code indicates RoHS status only. Package drawings may show a different suffix character, but the drawing pertains to the package regardless of RoHS status.

### Ordering Information/Selector Guide

*Note: The 4-digit suffix "-0000" indicates a microcontroller in the default state with the flash memory unprogrammed. Any value other than 0000 indicates a device preprogrammed at Maxim with proprietary customer-supplied software. For more information on factory preprogramming of these devices, contact Maxim at [https://support.maximintegrated.com/micro](http://https://support.maximintegrated.com/micro). Information on masked ROM devices and bare die versions for most of these devices are available. Contact the factory for availability.*

+*Denotes a lead(Pb)-free/RoHS-compliant package.*
