## 3 Hardware Design Considerations

### 3.1 PLL Power Filtering

To further enhance noise isolation, an external filter is strongly recommended for PLL analog  $V_{DD}$  pins. The filter shown in Figure 2 should be connected between the board  $V_{DD}$  and the  $PLL V_{DD}$  pins. The resistor and capacitors should be placed as close to the dedicated  $PLL V_{DD}$  pin as possible.

Figure 2. System  $PLL V_{DD}$  Power Filter

### 3.2 USB Power Filtering

To minimize noise, external filters are required for each of the USB power pins. The filter shown in Figure 3 should be connected between the board  $EV_{DD}$  or  $IV_{DD}$  and each of the  $USB V_{DD}$  pins. The resistor and capacitors should be placed as close to the dedicated  $USB V_{DD}$  pin as possible.

Figure 3. USB  $V_{DD}$  Power Filter

#### NOTE

In addition to the above filter circuitry, a 0.01 F capacitor is also recommended in parallel with those shown.

### 3.3 Supply Voltage Sequencing and Separation Cautions

The relationship between  $SDV_{DD}$  and  $EV_{DD}$  is non-critical during power-up and power-down sequences.  $SDV_{DD}$  (2.5V or 3.3V) and  $EV_{DD}$  are specified relative to  $IV_{DD}$ .

#### 3.3.1 Power Up Sequence

If  $EV_{DD}/SDV_{DD}$  are powered up with  $IV_{DD}$  at 0 V, the sense circuits in the I/O pads cause all pad output drivers connected to the  $EV_{DD}/SDV_{DD}$  to be in a high impedance state. There is no limit on how long after  $EV_{DD}/SDV_{DD}$  powers up before  $IV_{DD}$  must powered up.  $IV_{DD}$  should not lead the  $EV_{DD}$ ,  $SDV_{DD}$ , or  $PLL V_{DD}$  by more than 0.4 V during power ramp-up or there is

high current in the internal ESD protection diodes. The rise times on the power supplies should be slower than 500 us to avoid turning on the internal ESD protection clamp diodes.

### 3.3.2 Power Down Sequence

If  $IV_{DD}/PLL_{V_{DD}}$  are powered down first, sense circuits in the I/O pads cause all output drivers to be in a high impedance state. There is no limit on how long after  $IV_{DD}$  and  $PLL_{V_{DD}}$  power down before  $EV_{DD}$  or  $SDV_{DD}$  must power down.  $IV_{DD}$  should not lag  $EV_{DD}$ ,  $SDV_{DD}$ , or  $PLL_{V_{DD}}$  going low by more than 0.4 V during power down or there is undesired high current in the ESD protection diodes. There are no requirements for the fall times of the power supplies.

The recommended power down sequence is as follows:

1. Drop  $IV_{DD}/PLL_{V_{DD}}$  to 0 V.
2. Drop  $EV_{DD}/SDV_{DD}$  supplies.

## 4 Pin Assignments and Reset States

### 4.1 Signal Multiplexing

The following table lists all the MCF532x pins grouped by function. The Dir column is the direction for the primary function of the pin only. Refer to [Section 7, “Package Information,”](#) for package diagrams. For a more detailed discussion of the MCF532x signals, consult the *MCF5329 Reference Manual (MCF5329RM)*.

#### NOTE

In this table and throughout this document, a single signal within a group is designated without square brackets (i.e., A23), while designations for multiple signals within a group use brackets (i.e., A[23:21]) and is meant to include all signals within the two bracketed numbers when these numbers are separated by a colon.

#### NOTE

The primary functionality of a pin is not necessarily its default functionality. Pins that are muxed with GPIO default to their GPIO functionality.

<sup>1</sup> Refers to pin's primary function.

<sup>2</sup> Pull-up enabled internally on this signal for this mode.

<sup>3</sup> The SDRAM functions of these signals are not programmable by the user. They are dynamically switched by the processor when accessing SDRAM memory space and are included here for completeness.

<sup>4</sup> Primary functionality selected by asserting the DRAMSEL signal (SDR mode). Alternate functionality selected by negating the DRAMSEL signal (DDR mode). The GPIO module is not responsible for assigning these pins.

<sup>5</sup> GPIO functionality is determined by the edge port module. The GPIO module is only responsible for assigning the alternate functions.

<sup>6</sup> If JTAG\_EN is asserted, these pins default to Alternate 1 (JTAG) functionality. The GPIO module is not responsible for assigning these pins.

<sup>7</sup> Pull-down enabled internally on this signal for this mode.

<sup>8</sup> Must be left floating for proper operation of the PLL.

## 5 Electrical Characteristics

This document contains electrical specification tables and reference timing diagrams for the MCF5329 microcontroller unit. This section contains detailed information on power considerations, DC/AC electrical characteristics, and AC timing specifications of MCF5329.

The electrical specifications are preliminary and are from previous designs or design simulations. These specifications may not be fully tested or guaranteed at this early stage of the product life cycle. However, for production silicon, these specifications will be met. Finalized specifications will be published after complete characterization and device qualifications have been completed.

**NOTE**

The parameters specified in this MCU document supersede any values found in the module specifications.

**5.1 Maximum Ratings****Table 4. Absolute Maximum Ratings<sup>1, 2</sup>**

Rating	Symbol	Value	Unit
Core Supply Voltage	$IV_{DD}$	- 0.5 to +2.0	V
CMOS Pad Supply Voltage	$EV_{DD}$	- 0.3 to +4.0	V
DDR/Memory Pad Supply Voltage	$SDV_{DD}$	- 0.3 to +4.0	V
PLL Supply Voltage	$PLLV_{DD}$	- 0.3 to +2.0	V
Digital Input Voltage <sup>3</sup>	$V_{IN}$	- 0.3 to +3.6	V
Instantaneous Maximum Current Single pin limit (applies to all pins) <sup>3, 4, 5</sup>	$I_D$	25	mA
Operating Temperature Range (Packaged)	$T_A$ ( $T_L - T_H$ )	- 40 to +85	°C
Storage Temperature Range	$T_{stg}$	- 55 to +150	°C

<sup>1</sup> Functional operating conditions are given in [Section 5.4, “DC Electrical Specifications.”](#) Absolute maximum ratings are stress ratings only, and functional operation at the maxima is not guaranteed. Continued operation at these levels may affect device reliability or cause permanent damage to the device.

<sup>2</sup> This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level ( $V_{SS}$  or  $EV_{DD}$ ).

<sup>3</sup> Input must be current limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values for positive and negative clamp voltages, and then use the larger of the two values.

<sup>4</sup> All functional non-supply pins are internally clamped to  $V_{SS}$  and  $EV_{DD}$ .

<sup>5</sup> Power supply must maintain regulation within operating  $EV_{DD}$  range during instantaneous and operating maximum current conditions. If positive injection current ( $V_{in} > EV_{DD}$ ) is greater than  $I_D$ , the injection current may flow out of  $EV_{DD}$  and could result in external power supply going out of regulation. Ensure external  $EV_{DD}$  load shunts current greater than maximum injection current. This is the greatest risk when the MCU is not consuming power (ex; no clock). Power supply must maintain regulation within operating  $EV_{DD}$  range during instantaneous and operating maximum current conditions.

## 5.2 Thermal Characteristics

Table 5. Thermal Characteristics

Characteristic		Symbol	256MBGA	196MBGA	Unit
Junction to ambient, natural convection	Four layer board (2s2p)	$\theta_{JMA}$	37 <sup>1,2</sup>	42 <sup>1,2</sup>	°C/W
Junction to ambient (@200 ft/min)	Four layer board (2s2p)	$\theta_{JMA}$	34 <sup>1,2</sup>	38 <sup>1,2</sup>	°C/W
Junction to board	—	$\theta_{JB}$	27 <sup>3</sup>	32 <sup>3</sup>	°C/W
Junction to case	—	$\theta_{JC}$	16 <sup>4</sup>	19 <sup>4</sup>	°C/W
Junction to top of package	—	$\Psi_{jt}$	4 <sup>1,5</sup>	5 <sup>1,5</sup>	°C/W
Maximum operating junction temperature	—	$T_j$	105	105	°C

<sup>1</sup>  $\theta_{JMA}$  and  $\Psi_{jt}$  parameters are simulated in conformance with EIA/JESD Standard 51-2 for natural convection. Freescale recommends the use of  $\theta_{JmA}$  and power dissipation specifications in the system design to prevent device junction temperatures from exceeding the rated specification. System designers should be aware that device junction temperatures can be significantly influenced by board layout and surrounding devices. Conformance to the device junction temperature specification can be verified by physical measurement in the customer's system using the  $\Psi_{jt}$  parameter, the device power dissipation, and the method described in EIA/JESD Standard 51-2.

<sup>2</sup> Per JEDEC JESD51-6 with the board horizontal.

<sup>3</sup> Thermal resistance between the die and the printed circuit board in conformance with JEDEC JESD51-8. Board temperature is measured on the top surface of the board near the package.

<sup>4</sup> Thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC-883 Method 1012.1).

<sup>5</sup> Thermal characterization parameter indicating the temperature difference between package top and the junction temperature per JEDEC JESD51-2. When Greek letters are not available, the thermal characterization parameter is written in conformance with Psi-JT.

The average chip-junction temperature ( $T_j$ ) in °C can be obtained from:

$$T_j = T_A + (P_D \times \theta_{JMA}) \quad \text{Eqn. 1}$$

Where:

$T_A$	= Ambient Temperature, °C
$\theta_{JMA}$	= Package Thermal Resistance, Junction-to-Ambient, °C/W
$P_D$	= $P_{INT} + P_{I/O}$
$P_{INT}$	= $I_{DD} \times IV_{DD}$ , Watts - Chip Internal Power
$P_{I/O}$	= Power Dissipation on Input and Output Pins - User Determined

For most applications  $P_{I/O} < P_{INT}$  and can be ignored. An approximate relationship between  $P_D$  and  $T_j$  (if  $P_{I/O}$  is neglected) is:

$$P_D = \frac{K}{(T_j + 273^\circ C)} \quad \text{Eqn. 2}$$

Solving equations 1 and 2 for K gives:

$$K = P_D \times (T_A \times 273^\circ C) + \theta_{JMA} \times P_D^2 \quad \text{Eqn. 3}$$

## Electrical Characteristics

where K is a constant pertaining to the particular part. K can be determined from Equation 3 by measuring  $P_D$  (at equilibrium) for a known  $T_A$ . Using this value of K, the values of  $P_D$  and  $T_J$  can be obtained by solving Equation 1 and Equation 2 iteratively for any value of  $T_A$ .

## 5.3 ESD Protection

Table 6. ESD Protection Characteristics<sup>1, 2</sup>

Characteristics	Symbol	Value	Units
ESD Target for Human Body Model	HBM	2000	V

<sup>1</sup> All ESD testing is in conformity with CDF-AEC-Q100 Stress Test Qualification for Automotive Grade Integrated Circuits.

<sup>2</sup> A device is defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements. Complete DC parametric and functional testing is performed per applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

<sup>6</sup> This specification is the PLL lock time only and does not include oscillator start-up time.

<sup>7</sup>  $C_{PCB\_EXTAL}$  and  $C_{PCB\_XTAL}$  are the measured PCB stray capacitances on EXTAL and XTAL, respectively.

<sup>8</sup> Jitter is the average deviation from the programmed frequency measured over the specified interval at maximum  $f_{sys}$ . Measurements are made with the device powered by filtered supplies and clocked by a stable external clock signal. Noise injected into the PLL circuitry via PLL  $V_{DD}$ ,  $EV_{DD}$ , and  $V_{SS}$  and variation in crystal oscillator frequency increase the  $C_{jitter}$  percentage for a given interval.

<sup>9</sup> Values are with frequency modulation disabled. If frequency modulation is enabled, jitter is the sum of  $C_{jitter} + C_{mod}$ .

<sup>10</sup> Modulation percentage applies over an interval of 10  $\mu$ s, or equivalently the modulation rate is 100 KHz.

<sup>11</sup> Modulation range determined by hardware design.

## 5.6 External Interface Timing Characteristics

Table 9 lists processor bus input timings.

### NOTE

All processor bus timings are synchronous; that is, input setup/hold and output delay with respect to the rising edge of a reference clock. The reference clock is the FB\_CLK output.

All other timing relationships can be derived from these values. Timings listed in Table 9 are shown in Figure 7 and Figure 8.

\* The timings are also valid for inputs sampled on the negative clock edge.

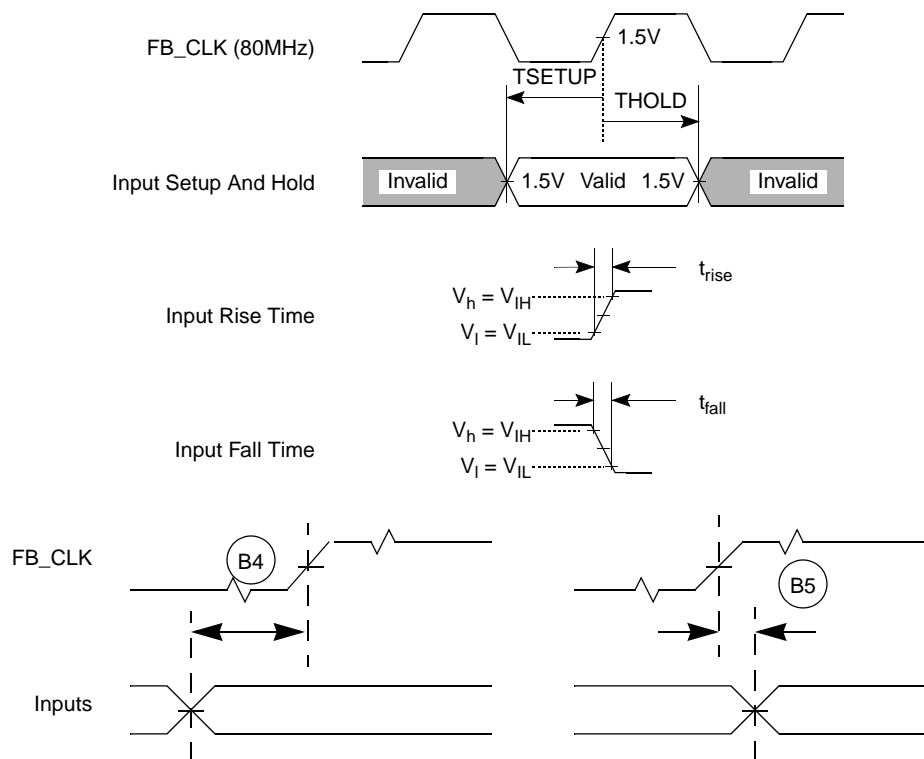

Figure 6. General Input Timing Requirements

## 5.6.1 FlexBus

A multi-function external bus interface called FlexBus is provided with basic functionality to interface to slave-only devices up to a maximum bus frequency of 80MHz. It can be directly connected to asynchronous or synchronous devices such as external boot ROMs, flash memories, gate-array logic, or other simple target (slave) devices with little or no additional circuitry. For asynchronous devices a simple chip-select based interface can be used. The FlexBus interface has six general purpose chip-selects ( $\overline{\text{FB\_CS}}[5:0]$ ) which can be configured to be distributed between the FlexBus or SDRAM memory interfaces. Chip-select,  $\overline{\text{FB\_CS}}0$  can be dedicated to boot ROM access and can be programmed to be byte (8 bits), word (16 bits), or longword (32 bits) wide. Control signal timing is compatible with common ROM/flash memories.

### 5.6.1.1 FlexBus AC Timing Characteristics

The following timing numbers indicate when data is latched or driven onto the external bus, relative to the system clock.

<sup>1</sup> Timing for chip selects only applies to the  $\overline{\text{FB\_CS}}[5:0]$  signals. Please see [Section 5.7.2, “DDR SDRAM AC Timing Characteristics”](#) for  $\overline{\text{SD\_CS}}[3:0]$  timing.

<sup>2</sup> The FlexBus supports programming an extension of the address hold. Please consult the *Reference Manual* for more information.

**NOTE**

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and SDRAM controller. At the end of the read and write bus cycles the address signals are indeterminate.

## 5.7 SDRAM Bus

The SDRAM controller supports accesses to main SDRAM memory from any internal master. It supports standard SDRAM or double data rate (DDR) SDRAM, but it does not support both at the same time.

### 5.7.1 SDR SDRAM AC Timing Characteristics

The following timing numbers indicate when data is latched or driven onto the external bus, relative to the memory bus clock, when operating in SDR mode on write cycles and relative to SD\_DQS on read cycles. The device's SDRAM controller is a DDR controller that has an SDR mode. Because it is designed to support DDR, a DQS pulse must remain supplied to the device for each data beat of an SDR read. The processor accomplishes this by asserting a signal named SD\_SDR\_DQS during read cycles. Care must be taken during board design to adhere to the following guidelines and specs with regard to the SD\_SDR\_DQS signal and its usage.

Table 10. SDR Timing Specifications

Symbol	Characteristic	Symbol	Min	Max	Unit

- <sup>1</sup> The FlexBus and SDRAM clock operates at the same frequency of the internal bus clock. See the PLL chapter of the *MCF5329 Reference Manual* for more information on setting the SDRAM clock rate.
- <sup>2</sup> SD\_CLK is one SDRAM clock in (ns).
- <sup>3</sup> Pulse width high plus pulse width low cannot exceed min and max clock period.
- <sup>4</sup> Pulse width high plus pulse width low cannot exceed min and max clock period.
- <sup>5</sup> SD\_DQS is designed to pulse 0.25 clock before the rising edge of the memory clock. This is a guideline only. Subtle variation from this guideline is expected. SD\_DQS only pulses during a read cycle and one pulse occurs for each data beat.
- <sup>6</sup> SDR\_DQS is designed to pulse 0.25 clock before the rising edge of the memory clock. This spec is a guideline only. Subtle variation from this guideline is expected. SDR\_DQS only pulses during a read cycle and one pulse occurs for each data beat.
- <sup>7</sup> The SDR\_DQS pulse is designed to be 0.5 clock in width. The timing of the rising edge is most important. The falling edge does not affect the memory controller.
- <sup>8</sup> Because a read cycle in SDR mode uses the DQS circuit within the device, it is most critical that the data valid window be centered 1/4 clk after the rising edge of DQS. Ensuring that this happens results in successful SDR reads. The input setup spec is provided as guidance.

### 5.7.2 DDR SDRAM AC Timing Characteristics

When using the SDRAM controller in DDR mode, the following timing numbers must be followed to properly latch or drive data onto the memory bus. All timing numbers are relative to the four DQS byte lanes.

<sup>1</sup> SD\_CLK is one SDRAM clock in (ns).

<sup>2</sup> Pulse width high plus pulse width low cannot exceed min and max clock period.

<sup>3</sup> Command output valid should be 1/2 the memory bus clock (SD\_CLK) plus some minor adjustments for process, temperature, and voltage variations.

<sup>4</sup> This specification relates to the required input setup time of today's DDR memories. The processor's output setup should be larger than the input setup of the DDR memories. If it is not larger, the input setup on the memory is in violation. MEM\_DATA[31:24] is relative to MEM\_DQS[3], MEM\_DATA[23:16] is relative to MEM\_DQS[2], MEM\_DATA[15:8] is relative to MEM\_DQS[1], and MEM\_[7:0] is relative MEM\_DQS[0].

<sup>5</sup> The first data beat is valid before the first rising edge of DQS and after the DQS write preamble. The remaining data beats are valid for each subsequent DQS edge.

<sup>6</sup> This specification relates to the required hold time of today's DDR memories. MEM\_DATA[31:24] is relative to MEM\_DQS[3], MEM\_DATA[23:16] is relative to MEM\_DQS[2], MEM\_DATA[15:8] is relative to MEM\_DQS[1], and MEM\_[7:0] is relative MEM\_DQS[0].

<sup>7</sup> Data input skew is derived from each DQS clock edge. It begins with a DQS transition and ends when the last data line becomes valid. This input skew must include DDR memory output skew and system level board skew (due to routing or other factors).

<sup>8</sup> Data input hold is derived from each DQS clock edge. It begins with a DQS transition and ends when the first data line becomes invalid.

<sup>1</sup> During low power STOP, the synchronizers for the  $\overline{\text{RESET}}$  input are bypassed and  $\overline{\text{RESET}}$  is asserted asynchronously to the system. Thus,  $\overline{\text{RESET}}$  must be held a minimum of 100 ns.

Num	Parameter	Minimum	Maximum	Unit
T1	LCD_LSCLK Period	25	2000	ns

## 5.11 USB On-The-Go

The MCF5329 device is compliant with industry standard USB 2.0 specification.

## 5.12 ULPI Timing Specification

Control and data timing requirements for the ULPI pins are given in Table 18. These timings apply in synchronous mode only. All timings are measured with either a 60 MHz input clock from the USB\_CLKIN pin. The USB\_CLKIN needs to maintain a 50% duty cycle. Control signals and 8-bit data are always clocked on the rising edge.

The ULPI interface on the MCF5329 processor is compliant with the industry standard definition.

## 5.13 SSI Timing Specifications

This section provides the AC timings for the SSI in master (clocks driven) and slave modes (clocks input). All timings are given for non-inverted serial clock polarity (SSI\_TCR[TSCPK] = 0, SSI\_RCR[RSCKP] = 0) and a non-inverted frame sync (SSI\_TCR[TFSI] = 0, SSI\_RCR[RFSI] = 0). If the polarity of the clock and/or the frame sync have been inverted, all the timings remain valid by inverting the clock signal (SSI\_BCLK) and/or the frame sync (SSI\_FS) shown in the figures below.

I9 <sup>1</sup>	Stop condition setup time	10	—	$t_{cyc}$

<sup>1</sup> Output numbers depend on the value programmed into the IFDR; an IFDR programmed with the maximum frequency (IFDR = 0x20) results in minimum output timings as shown in Table 22. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the SCL low period. The actual position is affected by the prescale and division values programmed into the IFDR; however, the numbers given in Table 22 are minimum values.

<sup>2</sup> Because I2C\_SCL and I2C\_SDA are open-collector-type outputs, which the processor can only actively drive low, the time I2C\_SCL or I2C\_SDA take to reach a high level depends on external signal capacitance and pull-up resistor values.

<sup>3</sup> Specified at a nominal 50-pF load.

Figure 22 shows timing for the values in Table 22 and Table 21.
