

## 12A Peak Low-Side MOSFET Drivers

### Features

- BiCMOS/DMOS Construction
- Latch-Up Proof: Fully Isolated Process is Inherently Immune to Any Latch-Up
- Input Will Withstand Negative Swing of up to 5V
- Matched Rise and Fall Times: 25 ns
- High Peak Output Current: 12A
- Wide Operating Range: 4.5V to 18V
- High Capacitive Load Drive: 62,000 pF
- Low Delay Time: 30 ns (typ.)
- Logic High Input for Any Voltage from 2.4V to  $V_S$
- Low Supply Current 450  $\mu$ A with Logic 1 Input
- Low Output Impedance: 1.0 $\Omega$
- Output Voltage Swing to within 25 mV of GND or  $V_S$
- Low Equivalent Input Capacitance: 7 pF (typ.)

### Applications

- Switch Mode Power Supplies
- Motor Controls
- Pulse Transformer Driver
- Class-D Switching Amplifier
- Line Drivers
- Driving MOSFET or IGBT Parallel Chip Modules
- Local Power ON/OFF Switch
- Pulse Generators

### General Description

The MIC4451 and MIC4452 CMOS MOSFET drivers are robust, efficient, and easy to use. The MIC4451 is an inverting driver, while the MIC4452 is a non-inverting driver.

Both versions are capable of 12A (peak) output and can drive the largest MOSFETs with an improved safe operating margin. The MIC4451/52 accept any logic input from 2.4V to  $V_S$  without external speed-up capacitors or resistor networks. Proprietary circuits allow the input to swing negative by as much as 5V without damaging the part. Additional circuits protect against damage from electrostatic discharge.

MIC4451/52 drivers can replace three or more discrete components, reducing PCB area requirements, simplifying product design, and reducing assembly cost.

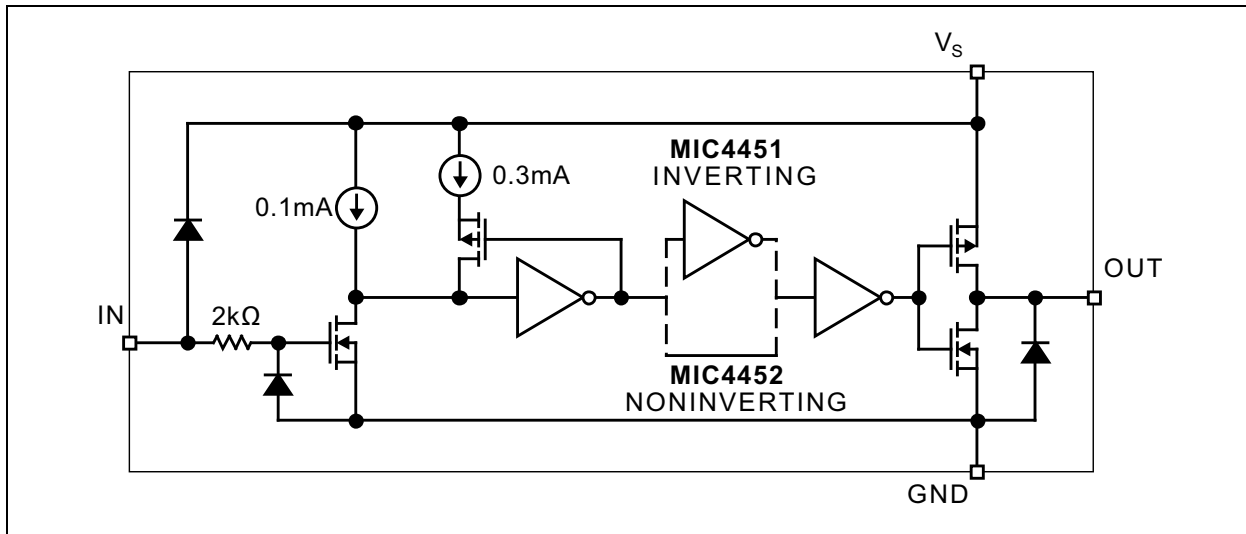

Modern Bipolar/CMOS/DMOS construction ensures freedom from latch-up. The rail-to-rail swing capability of CMOS/DMOS ensures adequate gate voltage to the MOSFET during power up/down sequencing. Because these devices are fabricated on a self-aligned process, they have very low crossover current, run cool, use little power, and are easy to drive.

## Functional Block Diagram

## 1.0 ELECTRICAL CHARACTERISTICS

### Absolute Maximum Ratings †

Supply Voltage .....	+20V
Input Voltage .....	$V_S + 0.3V$ to GND – 5V
Input Current ( $V_{IN} > V_S$ ) .....	5 mA
Power Dissipation ( $T_A \leq 25^\circ\text{C}$ )	
PDIP .....	960 mW
SOIC .....	1040 mW
TO-220 .....	2W
Power Dissipation ( $T_{CASE} \leq 25^\circ\text{C}$ )	
TO-220 .....	12.5W
Derating Factors (to Ambient)	
PDIP .....	7.7 mW/°C
SOIC .....	8.3 mW/°C
TO-220 .....	17 mW/°C

† **Notice:** Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational sections of this specification is not intended. Exposure to maximum rating conditions for extended periods may affect device reliability. Static-sensitive device. Store only in conductive containers. Handling personnel and equipment should be grounded to prevent damage from static discharge.

## ELECTRICAL CHARACTERISTICS

**Electrical Characteristics:**  $T_A = +25^\circ\text{C}$ , with  $4.5V \leq V_S \leq 18V$  unless otherwise specified.

Parameter	Symbol	Min.	Typ.	Max.	Units	Conditions

		—	—	0.4		$V_{IN} = 0\text{V}$
Operating Input Voltage	$V_S$	4.5	—	18	V	—

**Note 1:** Specification for packaged product only.

## TEMPERATURE SPECIFICATIONS (Note 1)

Parameters	Sym.	Min.	Typ.	Max.	Units	Conditions
<b>Temperature Ranges</b>						
Ambient Operating Temperature Range	$T_A$	0	—	+70	°C	Z Ordering Option
		-40	—	+85	°C	Y Ordering Option
		-40	—	+125	°C	V Ordering Option
Storage Temperature Range	$T_S$	-65	—	+150	°C	—
Chip Operating Temperature	—	—	—	+150	°C	—
Lead Temperature	—	—	—	+300	°C	Soldering, 10 sec.
<b>Package Thermal Resistance</b>						
Thermal Resistance, TO-220 5-Ld	$\theta_{JC}$	—	10	—	°C/W	—

**Note 1:** The maximum allowable power dissipation is a function of ambient temperature, the maximum allowable junction temperature and the thermal resistance from junction to air (i.e.,  $T_A$ ,  $T_J$ ,  $\theta_{JA}$ ). Exceeding the maximum allowable power dissipation will cause the device operating junction temperature to exceed the maximum +125°C rating. Sustained junction temperatures above +125°C can impact the device reliability.

## 4.0 APPLICATIONS INFORMATION

### 4.1 Supply Bypassing

Charging and discharging large capacitive loads quickly requires large currents. For example, changing a 10,000 pF load to 18V in 50 ns requires 3.6A.

The MIC4451 and MIC4452 have double bonding on the supply pins, the ground pins, and output pins. This reduces parasitic lead inductance. Low inductance enables large currents to be switched rapidly. It also reduces internal ringing that can cause voltage breakdown when the driver is operated at or near the maximum rated voltage.

Internal ringing can also cause output oscillation due to feedback. This feedback is added to the input signal because it is referenced to the same ground.

To ensure low supply impedance over a wide frequency range, a parallel capacitor combination is recommended for supply bypassing. Low inductance ceramic disc capacitors with short lead lengths (<0.5 inch) should be used. A 1  $\mu$ F low ESR film capacitor in parallel with two 0.1  $\mu$ F low ESR ceramic capacitors, (such as AVX RAM GUARD<sup>®</sup>), provides adequate bypassing. Connect one ceramic capacitor directly between pins 1 and 4. Connect the second ceramic capacitor directly between pins 8 and 5.

### 4.2 Grounding

The high current capability of the MIC4451/52 demands careful PC board layout for best performance. Because the MIC4451 is an inverting driver, any ground lead impedance will appear as negative feedback which can degrade switching speed. Feedback is especially noticeable with slow rise time inputs. The MIC4451 input structure includes 200 mV of hysteresis to ensure clean transitions and freedom from oscillation, but attention to layout is still recommended.

Figure 4-1 shows the feedback effect in detail. As the MIC4451 input begins to go positive, the output goes negative and several amperes of current flow in the ground lead. As little as 0.05 $\Omega$  of PC trace resistance can produce hundreds of millivolts at the MIC4451 ground pins. If the driving logic is referenced to power ground, the effective logic input level is reduced and oscillation may result.

To ensure optimum performance, separate ground traces should be provided for the logic and power connections. Connecting the logic ground directly to the MIC4451 GND pins will ensure full logic drive to the input and ensure fast output switching. Both of the MIC4451 GND pins should, however, still be connected to power ground.

### 4.3 Input Stage

The input voltage level of the MIC4451 changes the quiescent supply current. The N-channel MOSFET input stage transistor drives a 320  $\mu$ A current source load. With a logic “1” input, the maximum quiescent supply current is 400  $\mu$ A. Logic “0” input level signals reduce quiescent current to 80  $\mu$ A typical.

The MIC4451/52 input is designed to provide 200 mV of hysteresis. This provides clean transitions, reduces noise sensitivity, and minimizes output stage current spiking when changing states. Input voltage threshold level is approximately 1.5V, making the device TTL-compatible over the full temperature and operating supply voltage ranges. Input current is less than  $\pm 10$   $\mu$ A.

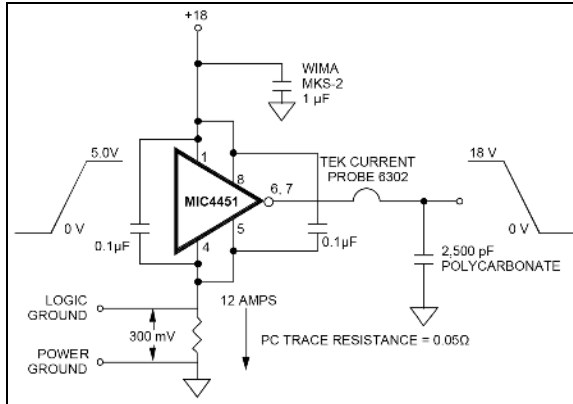

The MIC4451 can be directly driven by the TL494, SG1526/1527, SG1524, TSC170, MIC38C42, and similar switch mode power supply integrated circuits. By offloading the power-driving duties to the MIC4451/52, the power supply controller can operate at lower dissipation. This can improve performance and reliability.

The input can be greater than the  $V_S$  supply, however, current will flow into the input lead. The input currents can be as high as 30 mA peak-to-peak (6.4 mA<sub>RMS</sub>) with the input. No damage will occur to MIC4451/52, however, and it will not latch.

The input appears as a 7 pF capacitance and does not change even if the input is driven from an AC source. While the device will operate and no damage will occur up to 25V below the negative rail, input current will increase up to 1 mA/V due to the clamping action of the input, ESD diode, and 1 k $\Omega$  resistor.

### 4.4 Power Dissipation

CMOS circuits usually permit the user to ignore power dissipation. Logic families, such as 4000 and 74C, have outputs that can only supply a few milliamperes of current, and even shorting outputs to ground will not force enough current to destroy the device. The MIC4451/52 on the other hand, can source or sink several amperes and drive large capacitive loads at high frequency. The package power dissipation limit can easily be exceeded. Therefore, some attention should be given to power dissipation when driving low impedance loads and/or operating at high frequency.

**FIGURE 4-1:** Switching Time Degradation Due to Negative Feedback.

The supply current vs. frequency and supply current vs capacitive load characteristic curves aid in determining power dissipation calculations. Table 4-1 lists the maximum safe operating frequency for several power supply voltages when driving a 10,000 pF load. More accurate power dissipation figures can be obtained by summing the three dissipation sources.

Given the power dissipation in the device and the thermal resistance of the package, junction operating temperature for any ambient is easy to calculate. For example, the thermal resistance of the 8-lead plastic DIP package, from the data sheet, is 130°C/W. In a 25°C ambient, then, using a maximum junction temperature of 125°C, this package will dissipate 960 mW.

Accurate power dissipation numbers can be obtained by summing the three sources of power dissipation in the device:

- Load Power Dissipation ( $P_L$ )
- Quiescent power dissipation ( $P_Q$ )
- Transition power dissipation ( $P_T$ )

Calculation of load power dissipation differs depending on whether the load is capacitive, resistive or inductive.

## 4.5 Resistive Load Power Dissipation

Dissipation caused by a resistive load can be calculated as:

### EQUATION 4-1:

$$P_L = I^2 \times R_O \times D$$

Where:

I = The current drawn by the load.

$R_O$  = The output resistance of the driver when the output is high, at the power supply voltage used.

D = The fraction of time the load is conducting (duty cycle).

## 4.6 Capacitive Load Power Dissipation

Dissipation caused by a capacitive load is simply the energy placed in, or removed from, the load capacitance by the driver. The energy stored in a capacitor is described by the equation:

### EQUATION 4-2:

$$E = \frac{1}{2} \times C \times V^2$$

**TABLE 4-1: MIC4451 MAX. OPERATION FREQUENCY**

$V_S$	Max. Frequency
18V	220 kHz
15V	300 kHz
10V	640 kHz
5V	2 MHz

Because this energy is lost in the driver each time the load is charged or discharged, the "1/2" is removed for power dissipation calculations. This equation also shows that it is good practice not to place more voltage on the capacitor than is necessary, as dissipation increases as the square of the voltage applied to the capacitor. For a driver with a capacitive load:

### EQUATION 4-3:

$$P_L = f \times C \times (V_S)^2$$

Where:

f = Operating frequency.

C = Load capacitance.

$V_S$  = Driver supply voltage.

## 4.7 Inductive Load Power Dissipation

For inductive loads, the situation is more complicated. For the part of the cycle in which the driver is actively forcing current into the inductor, the situation is the same as it is in the resistive case:

### EQUATION 4-4:

$$P_{L1} = I^2 \times R_O \times D$$

# MIC4451/52

In this instance, however, the  $R_O$  required may be either the ON resistance of the driver when its output is in the high state, or its ON resistance when the driver is in the low state, depending on how the inductor is connected, and this is still only half the story. For the part of the cycle when the inductor is forcing current through the driver, dissipation is best described as:

## EQUATION 4-5:

$$P_{L2} = I \times V_D \times (1 - D)$$

Where:

$V_D$  = The forward drop of the clamp diode in the driver (generally around 0.7V).

The two parts of the load dissipation must be summed in to produce  $P_L$ :

## EQUATION 4-6:

$$P_L = P_{L1} + P_{L2}$$

## 4.8 Quiescent Power Dissipation

Quiescent power dissipation ( $P_Q$ , as described in the input section) depends on whether the input is high or low. A low input will result in a maximum current drain (per driver) of  $\leq 0.2$  mA; a logic high will result in a current drain of  $\leq 3.0$  mA. Quiescent power can therefore be derived from:

## EQUATION 4-7:

$$P_Q = V_S \times [D \times I_H + (1 - D) \times I_L]$$

Where:

$I_H$  = Quiescent current with input high.

$I_L$  = Quiescent current with input low.

$D$  = Fraction of time the input is high (duty cycle).

$V_S$  = Power supply voltage.

## 4.9 Transition Power Dissipation

Transition power is dissipated in the driver each time its output changes state because during the transition, for a very brief interval, both the N- and P-channel MOSFETs in the output totem-pole are ON simultaneously and a current is conducted through them from  $V_S$  to ground. The transition power dissipation is approximately:

## EQUATION 4-8:

$$P_T = 2 \times f \times V_S \times (A \times s)$$

Where:

( $A \times s$ ) = A time-current factor derived from [Figure 2-6](#)

Total power ( $P_D$ ) then, as previously described is:

## EQUATION 4-9:

$$P_D = P_L + P_Q + P_T$$

## 4.10 Definitions

$C_L$  = Load Capacitance in Farads.

$D$  = Duty Cycle expressed as the fraction of time the input to the driver is high.

$f$  = Operating Frequency of the driver in Hertz

$I_H$  = Power supply current drawn by a driver when both inputs are high and neither output is loaded.

$I_L$  = Power supply current drawn by a driver when both inputs are low and neither output is loaded.

$I_D$  = Output current from a driver in Amps.

$P_D$  = Total power dissipated in a driver in Watts.

$P_L$  = Power dissipated in the driver due to the driver's load in Watts.

$P_Q$  = Power dissipated in a quiescent driver in Watts.

$P_T$  = Power dissipated in a driver when the output changes states (shoot-through current) in watts.

$R_O$  = Output resistance of a driver in Ohms.

$V_S$  = Power supply voltage to the IC in volts.

## 5.0 PACKAGING INFORMATION

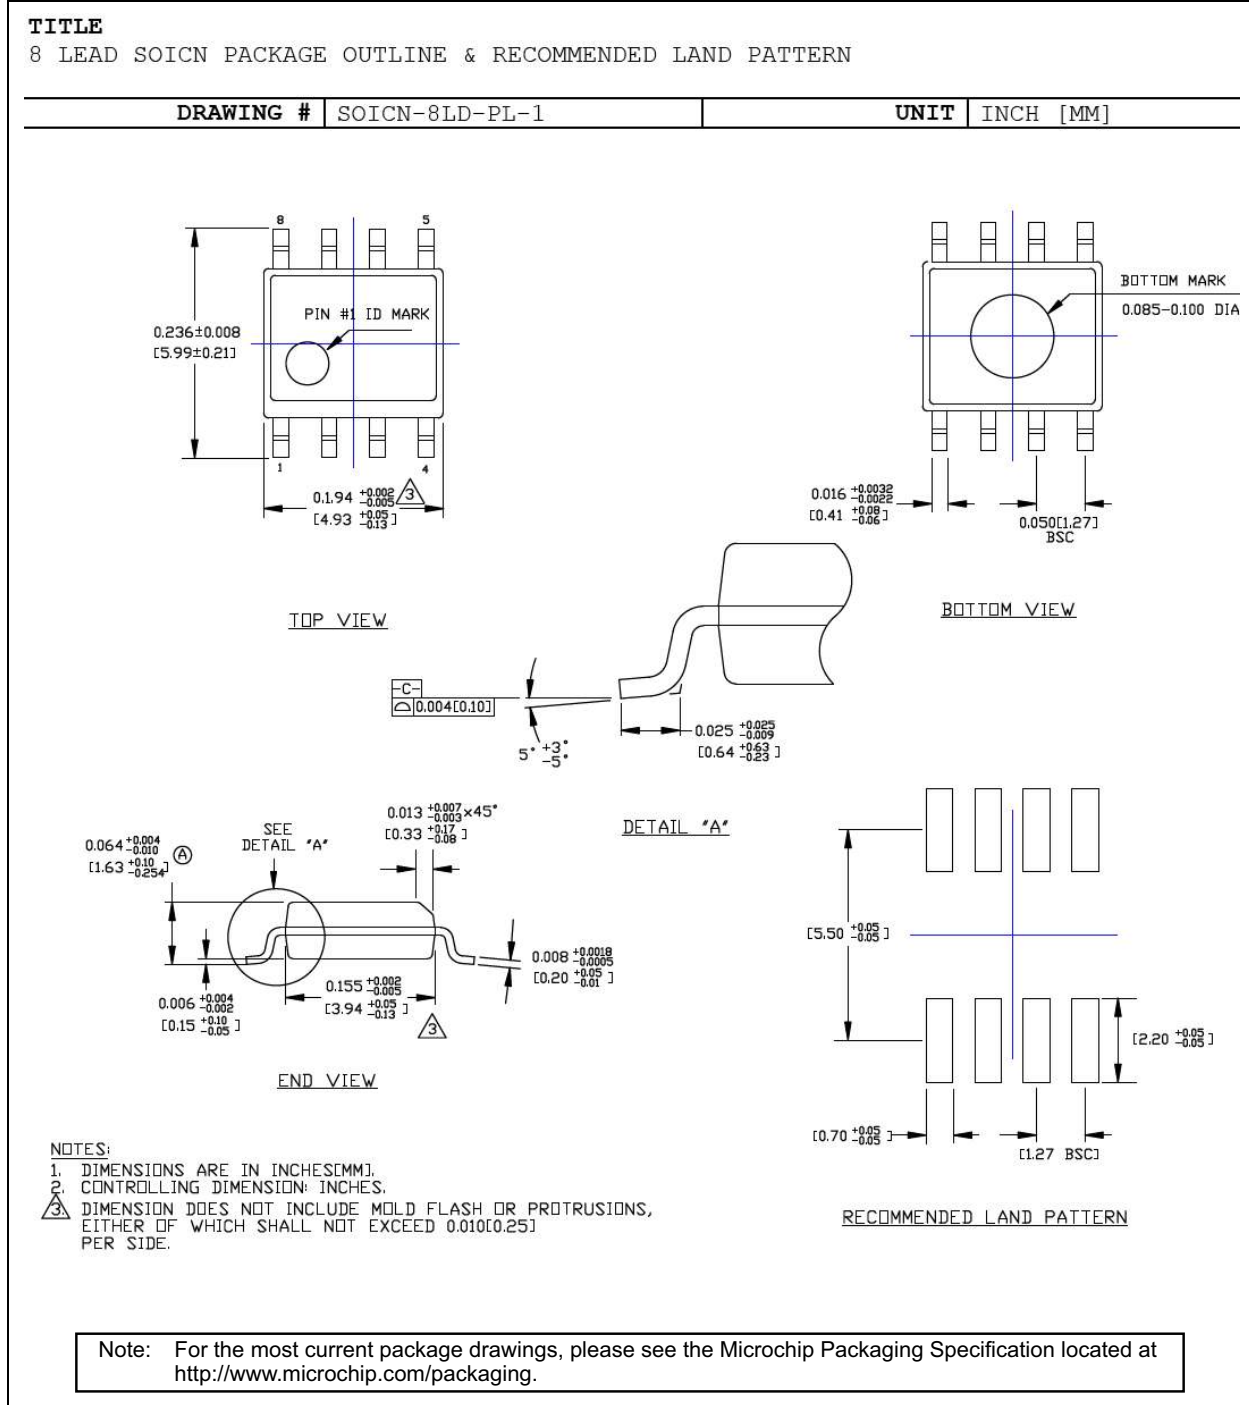

### 5.1 Package Marking Information

<b>Legend:</b>	XX...X	Product code or customer-specific information
	Y	Year code (last digit of calendar year)
	YY	Year code (last 2 digits of calendar year)
	WW	Week code (week of January 1 is week '01')
	NNN	Alphanumeric traceability code
	(e3)	Pb-free JEDEC® designator for Matte Tin (Sn)
	*	This package is Pb-free. The Pb-free JEDEC designator (e3) can be found on the outer packaging for this package.
	•, ▲, ▼	Pin one index is identified by a dot, delta up, or delta down (triangle mark).
<b>Note:</b>	In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information. Package may or may not include the corporate logo.	
	Underbar (¯) and/or Overbar (¯) symbol may not be to scale.

NOTES:

---

---

**Note the following details of the code protection feature on Microchip products:**

- Microchip products meet the specifications contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is secure when used in the intended manner, within operating specifications, and under normal conditions.
- Microchip values and aggressively protects its intellectual property rights. Attempts to breach the code protection features of Microchip product is strictly prohibited and may violate the Digital Millennium Copyright Act.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of its code. Code protection does not mean that we are guaranteeing the product is “unbreakable”. Code protection is constantly evolving. Microchip is committed to continuously improving the code protection features of our products.

This publication and the information herein may be used only with Microchip products, including to design, test, and integrate Microchip products with your application. Use of this information in any other manner violates these terms. Information regarding device applications is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. Contact your local Microchip sales office for additional support or, obtain additional support at <https://www.microchip.com/en-us/support/design-help/client-support-services>.

THIS INFORMATION IS PROVIDED BY MICROCHIP "AS IS". MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION INCLUDING BUT NOT LIMITED TO ANY IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY, AND FITNESS FOR A PARTICULAR PURPOSE, OR WARRANTIES RELATED TO ITS CONDITION, QUALITY, OR PERFORMANCE.

IN NO EVENT WILL MICROCHIP BE LIABLE FOR ANY INDIRECT, SPECIAL, PUNITIVE, INCIDENTAL, OR CONSEQUENTIAL LOSS, DAMAGE, COST, OR EXPENSE OF ANY KIND WHATSOEVER RELATED TO THE INFORMATION OR ITS USE, HOWEVER CAUSED, EVEN IF MICROCHIP HAS BEEN ADVISED OF THE POSSIBILITY OR THE DAMAGES ARE FORESEEABLE. TO THE FULLEST EXTENT ALLOWED BY LAW, MICROCHIP'S TOTAL LIABILITY ON ALL CLAIMS IN ANY WAY RELATED TO THE INFORMATION OR ITS USE WILL NOT EXCEED THE AMOUNT OF FEES, IF ANY, THAT YOU HAVE PAID DIRECTLY TO MICROCHIP FOR THE INFORMATION.

Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.
