## 5. Special Port / Resource Assignments

In general, the port / resource assignments and the necessary register settings (PFR, EPFR) are described in the CY91460 series hardware manual. The assignments of CY91460Q series are different on some ports. This chapter explains the differences and the settings needed to enable the resources.

### 5.1 Overview of Special Port / Resource Assignments

- CY91460Q series has a second A/D converter (ADC1), serving the channels AN34-39, AN42 and AN46. These analog channels are added to P17[7:2], P18[6] and P18[2].
- CY91460Q series has 16 more external interrupts (INT16-31), added to ports 27 and 26.
- The following external interrupts are re-located to other ports then described in the hardware manual: INT4, INT5, INT10, INT11, INT12, INT14.
- CY91460Q series has 2 more Input Capture Units (ICU8, ICU9) and one more Free Run Timer (FRT8).
- CY91460Q series has different initial function of the external bus IOs

### 5.2 The Second A/D Converter (ADC1)

The second ADC is of the same macro type then ADC0 (10 bit, 1 $\mu$ s), and it has the same register set.

For the addresses, please refer to the IO MAP at address 0x5E0 to 0x5EB.

The external trigger signal (ATGX) for ADC1 comes from port P16[7] and is the same as for ADC0.

The internal trigger signal for ADC1 comes from Reload Timer 7 and is the same as for ADC0.

The analog input channels are assigned to the following bits of Ports 17 and 18:

Port 17								Func.	Enabled by
P17[7]	P17[6]	P17[5]	P17[4]	P17[3]	P17[2]	P17[1]	P17[0]	GPIO	PFR17=0
PPG7	PPG6	PPG5	PPG4	PPG3	PPG2	PPG1	PPG0	PPG	PFR17=1
<b>AN39</b>	<b>AN38</b>	<b>AN37</b>	<b>AN36</b>	<b>AN35</b>	<b>AN34</b>	-	-	<b>ADC1</b>	<b>AD1ER[m-32]=1</b>

Port 18								Func.	Enabled by
-	P18[6]	P18[5]	P18[4]	-	P18[2]	P18[1]	P18[0]	GPIO	PFR18=0
-	SCK7	SOT7	SIN7	-	SCK6	SOT6	SIN6	LIN	PFR18=1, EPFR18=0
	ZIN3, CK7	BIN3	AIN3	-	ZIN2, CK6	BIN2	AIN2	UDC, FRT	PFR18=1, EPFR18=1
-	<b>AN46</b>	-	-	-	<b>AN42</b>	-	-	<b>ADC1</b>	<b>AD1ER[m-32]=1</b>

m = 32 to 46 (ADC channel)

The analog channel IO is enabled independently of PFR/EPFR. It only depends on the appropriate **AD1ER[n]** bit (ADC channel enable). If an analog channel is enabled, the digital input stages are disabled by hardware. **Analog overwrites digital input.**

### 5.3 The Additional External Interrupts (INT16-31)

The additional external interrupts are controlled by a second external interrupt controller having similar register set.

For the addresses, please refer to the IO MAP at address 0xC04 to 0xC0B.

The new interrupt functions are assigned to the ports 26 and 27:

Port 26								Func.	Enabled by
P26[7]	P26[6]	P26[5]	P26[4]	P26[3]	P26[2]	P26[1]	P26[0]	GPIO	PFR26=0
-	-	-	-	-	-	-	-	[SMC]	PFR26=1, EPFR26=0
AN31	AN30	AN29	AN28	AN27	AN26	AN25	AN24	ADC0	PFR26=1, EPFR26=1
<b>INT31</b>	<b>INT30</b>	<b>INT29</b>	<b>INT28</b>	<b>INT27</b>	<b>INT26</b>	<b>INT25</b>	<b>INT24</b>	<b>INT</b>	<b>PFR27=1, EPFR27=1, ENIR3[m-24]=1 and ADERH[an-16]=0</b>

Port 27								Func.	Enabled by
P27[7]	P27[6]	P27[5]	P27[4]	P27[3]	P27[2]	P27[1]	P27[0]	GPIO	PFR27=0
-	-	-	-	-	-	-	-	[SMC]	PFR27=1, EPFR27=0
AN23	AN22	AN21	AN20	AN19	AN18	AN17	AN16	ADC0	PFR27=1, EPFR27=1
<b>INT23</b>	<b>INT22</b>	<b>INT21</b>	<b>INT20</b>	<b>INT19</b>	<b>INT18</b>	<b>INT17</b>	<b>INT16</b>	<b>INT</b>	<b>PFR27=1, EPFR27=1, ENIR2[m-16]=1 and ADERH[an-16]=0</b>

m = 16 to 31 (INT channel)

an = 16 to 31 (ADC channel)

Note: CY91460Q series does not have Stepper Motor Controllers (SMC). On other devices of CY91460 series, the SMC lines are located on ports 25 to 27 and enabled by setting PFR=1, EPFR=0.

The new interrupts are assigned to ports having analog functions (SMC, ADC).

**If an analog function is enabled on a pin, then all digital input functionality of this pin is disabled by hardware, and it is not possible to use the interrupt function. Analog overwrites digital input!**

The ADC functions are enabled by setting PFR=1, EPFR=1 and ADREH=1 (ADERH is ADC channel enable register of ADC0. If the ADC functions are enabled, the digital input lines are disabled. CMOS-Schmitt, Automotive and CMOS-2 level input lines keep their value (bus holder behaviour) while the TTL input line is tied to low level. In this state, external interrupts cannot be used.

If the analog functions are disabled (ADREH=0), the interrupt can be used after setting the appropriate interrupt channel enable bit in ENIR2/EINR3 register as well as PFR and EPFR. Setting these registers enables the digital input stages for wakeup in STOP mode.

### 5.4 Re-located External Interrupts (INT4, INT5, INT10, INT11, INT12, INT14)

The re-located interrupts are assigned to ports different to other devices of CY91460 series:

Port 24	Port 35		Port 34			Func.	Enabled by
P24[4]	P35[4]	P35[0]	P34[5]	P34[4]	P34[0]	GPIO	PFR=0
SDA2	-	-	-	-	-	[LCD]	PFR=1, EPFR=0
-	SIN9	SIN8	SOT11	SIN11	SIN10	I2C/ LIN	PFR=1, EPFR=1
<b>INT14</b>	<b>INT12</b>	<b>INT11</b>	<b>INT5</b>	<b>INT4</b>	<b>INT10</b>	<b>ADC1</b>	<b>ENIR1/0[m]=1</b>

Note: CY91460Q series does not have the LCD Controller.

On other devices of CY91460 series, the LCD lines are located on ports 30 to 36 and enabled by setting PFR=1, EPFR=0. This setting would disable the digital input lines on other devices. To keep the software compatible to the new evaluation device, avoid setting PFR=1 & EPFR=0.

Note: Take care about INT5 because it is attached to SOT11 (LIN-USART output direction if PFR=EPFR=1!)

If the LCD function is disabled, the interrupt can be used after setting the appropriate interrupt channel enable bit in ENIR0/EINR1 register. Setting ENIR0/ENIR1 enables the digital input stages for wakeup in STOP mode. But setting ENIR does **not** switch the port direction to input mode. The user should take care that the port is operating in input direction before expecting external interrupts.

### 5.5 Input Capture Units (ICU8,9) and Free Run Timer (FRT8)

CY91460Q series has 2 more ICUs and one more FRT. The assignments are the following:

Port 22		Port 21	Func.	Enabled by	Comments
P22[7]	P22[6]	P21[2]	GPIO	PFR=0	
SCL1	SDA1	SCK0	I2C / LIN	PFR=1	Port 22 does not have EPFR.
-	INT15	-	INT	PFR=1	Port 22 does not have EPFR.
-	-	CK0/8	FRT	PFR=1, EPFR=1	PFR=1 & EPFR=1 just switches the port 21[2] to input direction. FRT8 uses the same input signal as FRT0.
<b>ICU9</b>	<b>ICU8</b>	-	<b>ICU</b>	<b>PFR=1 or PFR=0</b>	PFR switches the ICU input signal between LIN-US-ART.LSYNC and the pin.

PFR22[7:6] switch the input signals of the ICU modules 9 and 8:

PFR	Value	ICU input connection
<b>PFR22[7]</b>	0	ICU9 input is connected to port 22[7] input line (default)
	1	ICU9 input is connected to the LSYNC output of LIN-USART9
<b>PFR22[6]</b>	0	ICU8 input is connected to port 22[6] input line (default)
	1	ICU8 input is connected to the LSYNC output of LIN-USART8

Note: For ICU0-7, this multiplexing is controlled by EPFR14 register.

### 5.6 External Bus Function After Reset

Older devices of CY91460 series switch on the external bus after reset by setting the PFR registers of the ports 00 to 10. This behaviour appears in external vector fetch mode (MD[2:0]=001) as well as in internal vector fetch mode (MD[2:0]=000). New devices of CY91460 series (including CY91460Q) do **not** switch on the external bus in internal vector fetch mode (MD[2:0]=000).

## 6. Handling Devices

### 6.1 Preventing Latch-up

Latch-up may occur in a CMOS IC if a voltage higher than ( $V_{DD5}$ ,  $V_{DD35}$ ) or less than ( $V_{SS5}$ ) is applied to an input or output pin or if a voltage exceeding the rating is applied between the power supply pins and ground pins. If latch-up occurs, the power supply current increases rapidly, sometimes resulting in thermal breakdown of the device. Therefore, be very careful not to apply voltages in excess of the absolute maximum ratings.

### 6.2 Handling of Unused Input Pins

If unused input pins are left open, abnormal operation may result. Any unused input pins should be connected to pull-up or pull-down resistor (2K $\Omega$  to 10K $\Omega$ ) or enable internal pullup or pulldown resistors (PPER/PPCR) before the input enable (PORTEN) is activated by software. The mode pins MD\_x can be connected to  $V_{SS5}$  or  $V_{DD5}$  directly. Unused ALARM input pins can be connected to  $AV_{SS5}$  directly.

### 6.3 Power Supply Pins

In CY91460Q series, devices including multiple power supply pins and ground pins are designed as follows; pins necessary to be at the same potential are interconnected internally to prevent malfunctions such as latch-up. All of the power supply pins and ground pins must be externally connected to the power supply and ground respectively in order to reduce unnecessary radiation, to prevent strobe signal malfunctions due to the ground level rising and to follow the total output current ratings. Furthermore, the power supply pins and ground pins of the CY91460Q series must be connected to the current supply source via a low impedance.

It is also recommended to connect a ceramic capacitor of approximately 0.1  $\mu$ F as a bypass capacitor between power supply pin and ground pin near this device.

This series has a built-in step-down regulator. Connect a bypass capacitor of 4.7  $\mu$ F (use a X7R ceramic capacitor) to VCC18C pin for the regulator.

### 6.4 Crystal Oscillator Circuit

Noise in proximity to the X0 (X0A) and X1 (X1A) pins can cause the device to operate abnormally. Printed circuit boards should be designed so that the X0 (X0A) and X1 (X1A) pins, and crystal oscillator, as well as bypass capacitors connected to ground, are located near the device and ground.

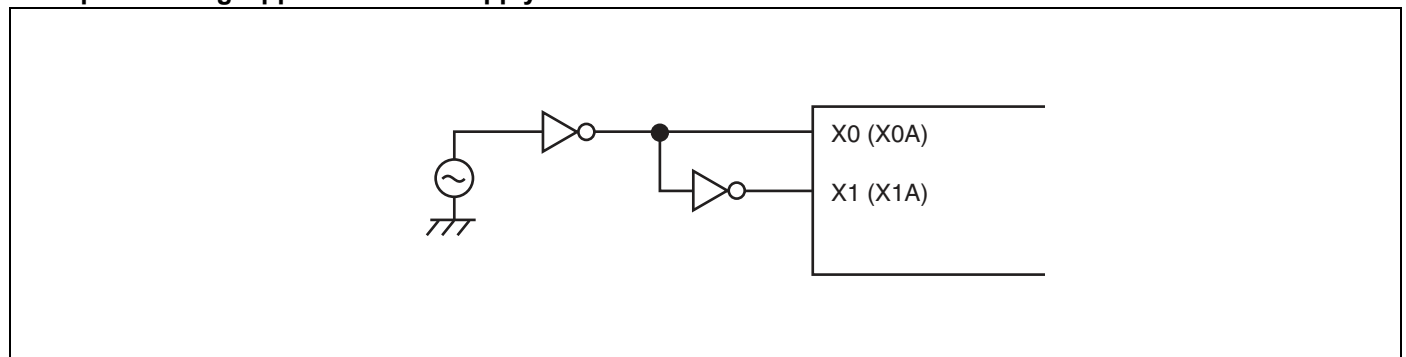

It is recommended that the printed circuit board layout be designed such that the X0 and X1 pins or X0A and X1A pins are surrounded by ground plane for the stable operation.

Please request the oscillator manufacturer to evaluate the oscillational characteristics of the crystal and this device.

### 6.5 Notes on Using External Clock

When using the external clock, it is necessary to simultaneously supply the X0 (X0A) and the X1 (X1A) pins. In the described combination, X1 (X1A) should be supplied with a clock signal which has the opposite phase to the X0 (X0A) pins. At X0 and X1, a frequency up to 16 MHz is possible.

#### Example of Using Opposite Phase Supply

## 6.6 Mode Pins (MD\_x)

These pins should be connected directly to the power supply or ground pins. To prevent the device from entering test mode accidentally due to noise, minimize the lengths of the patterns between each mode pin and power supply pin or ground pin on the printed circuit board as possible and connect them with low impedance.

## 6.7 Notes on Operating in PLL Clock Mode

If the oscillator is disconnected or the clock input stops when the PLL clock is selected, the microcontroller may continue to operate at the free-running frequency of the self-oscillating circuit of the PLL. However, this self-running operation cannot be guaranteed.

## 6.8 Pull-up Control

The AC standard is not guaranteed in case a pull-up resistor is connected to the pin serving as an external bus pin.

## 6.9 Notes on PS Register

As the PS register is processed in advance by some instructions, when the debugger is being used, the exception handling may result in execution breaking in an interrupt handling routine or the displayed values of the flags in the PS register being updated.

As the microcontroller is designed to carry out reprocessing correctly upon returning from such an EIT event, the operation before and after the EIT always proceeds according to specification.

### **The following behavior may occur if any of the following occurs in the instruction immediately after a DIV0U/DIV0S instruction:**

- (a) a user interrupt or NMI is accepted;
- (b) single-step execution is performed;
- (c) execution breaks due to a data event or from the emulator menu.
  - 1. D0 and D1 flags are updated in advance.
  - 2. An EIT handling routine (user interrupt/NMI or emulator) is executed.
  - 3. Upon returning from the EIT, the DIV0U/DIV0S instruction is executed and the D0 and D1 flags are updated to the same values as those in 1.

### **The following behavior occurs when an ORCCR, STILM, MOV Ri,PS instruction is executed to enable a user interrupt or NMI source while that interrupt is in the active state.**

- 1. The PS register is updated in advance.
- 2. An EIT handling routine (user interrupt/NMI or emulator) is executed.
- 3. Upon returning from the EIT, the above instructions are executed and the PS register is updated to the same value as in 1.

## 7. Notes on Debugger

### 7.1 Execution of the RETI Command

If single-step execution is used in an environment where an interrupt occurs frequently, the corresponding interrupt handling routine will be executed repeatedly to the exclusion of other processing. This will prevent the main routine and the handlers for low priority level interrupts from being executed (For example, if the time-base timer interrupt is enabled, stepping over the RETI instruction will always break on the first line of the time-base timer interrupt handler).

Disable the corresponding interrupts when the corresponding interrupt handling routine no longer needs debugging.

### 7.2 Break Function

If the range of addresses that cause a hardware break (including event breaks) is set to the address of the current system stack pointer or to an area that contains the stack pointer, execution will break after each instruction regardless of whether the user program actually contains data access instructions.

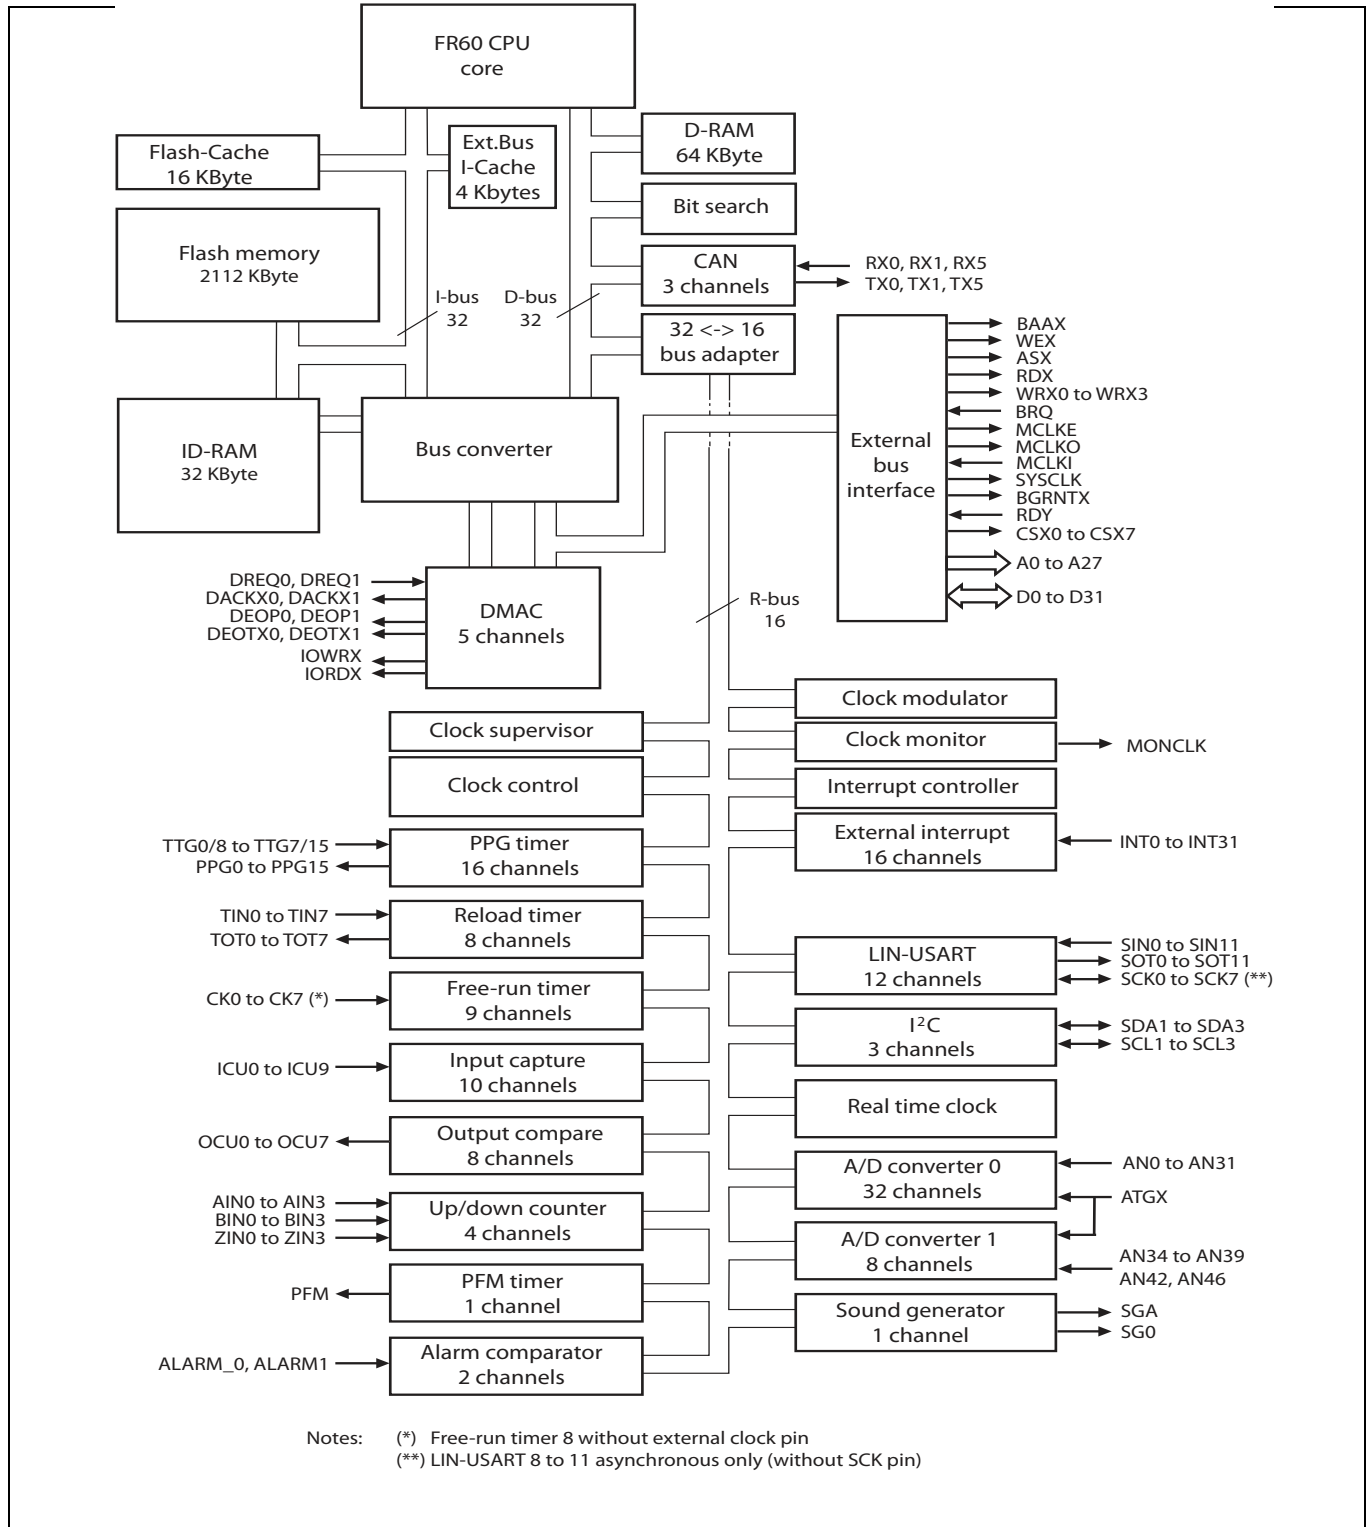

To prevent this, do not set (word) access to the area containing the address of the system stack pointer as the target of the hardware break (including an event breaks).

### 7.3 Operand Break

It may cause malfunctions if a stack pointer exists in the area which is set as the DSU operand break. Do not set the access to the areas containing the address of system stack pointer as a target of data event break.

*10.4.2 Pin Connections in Parallel Programming Mode*

Resetting after setting the MD[2:0] pins to [111] will halt CPU functioning. At this time, the Flash memory's interface circuit enables direct control of the Flash memory unit from external pins by directly linking some of the signals to General Purpose Ports. Please see table below for signal mapping.

In this mode, the Flash memory appears to the external pins as a stand-alone unit. This mode is generally set when writing/erasing using the parallel Flash programmer. In this mode, all operations of the 16.5 Mbits Flash memory's Auto Algorithms are available.

### 10.5 Poweron Sequence in Parallel Programming Mode

The flash memory can be accessed in programming mode after a certain wait time, which is needed for Security Vector fetch:

- Minimum wait time after VDD5/VDD5R power on : 2.76 ms
- Minimum wait time after INITX rising : 1.0 ms

### 10.6 Flash Security

#### 10.6.1 Vector Addresses

Two Flash Security Vectors (FSV1, FSV2) are located parallel to the Boot Security Vectors (BSV1, BSV2) controlling the protection functions of the Flash Security Module:

FSV1: 0x24:8000      BSV1: 0x24:8004  
 FSV2: 0x24:8008      BSV2: 0x24:800C

#### 10.6.2 Security Vector FSV1

The setting of the Flash Security Vector FSV1 is responsible for the read and write protection modes and the individual write protection of the 8 Kbytes sectors.

#### FSV1 (bit31 to bit16)

The setting of the Flash Security Vector FSV1 bits [31:16] is responsible for the read and write protection modes.

Explanation of the bits in the Flash Security Vector FSV1 [31:16]

FSV1 (bit15 to bit0)

The setting of the Flash Security Vector FSV1 bits [15:0] is responsible for the individual write protection of the 8 Kbytes sectors. It is only evaluated if write protection bit FSV1[17] is set.

Explanation of the bits in the Flash Security Vector FSV1 [15:0]

Note : It is mandatory to always set the sector where the Flash Security Vectors FSV1 and FSV2 are located to write protected (here sector SA4). Otherwise it is possible to overwrite the Security Vector to a setting where it is possible to either read out the Flash content or manipulate data by writing.

See section "Flash access in CPU mode" for an overview about the sector organization of the Flash Memory.

### 10.6.3 Security Vector FSV2

The setting of the Flash Security Vector FSV2 bits [31:0] is responsible for the individual write protection of the 64 Kbytes sectors. It is only evaluated if write protection bit FSV1 [17] is set.

### 10.7 Notes About Flash Memory CRC Calculation

The Flash Security macro contains a feature to calculate the 32-bit checksum over addresses located in the Flash Memory address space. This feature is described in the CY91460 Series Hardware Manual, chapter 55.4.1 "Flash Security Control Register".

Additional notes are given here:

The CRC calculation runs on the internal RC clock. It is recommended to switch the RC clock frequency to 2 MHz for shortening the calculation time. However, the CPU clock (CLKB) must be faster than RC clock, otherwise the CRC calculation may not start correctly.

## 11. Memory Space

The FR family has 4 Gbytes of logical address space ( $2^{32}$  addresses) available to the CPU by linear access.

### Direct Addressing Area

The following address space area is used for I/O.

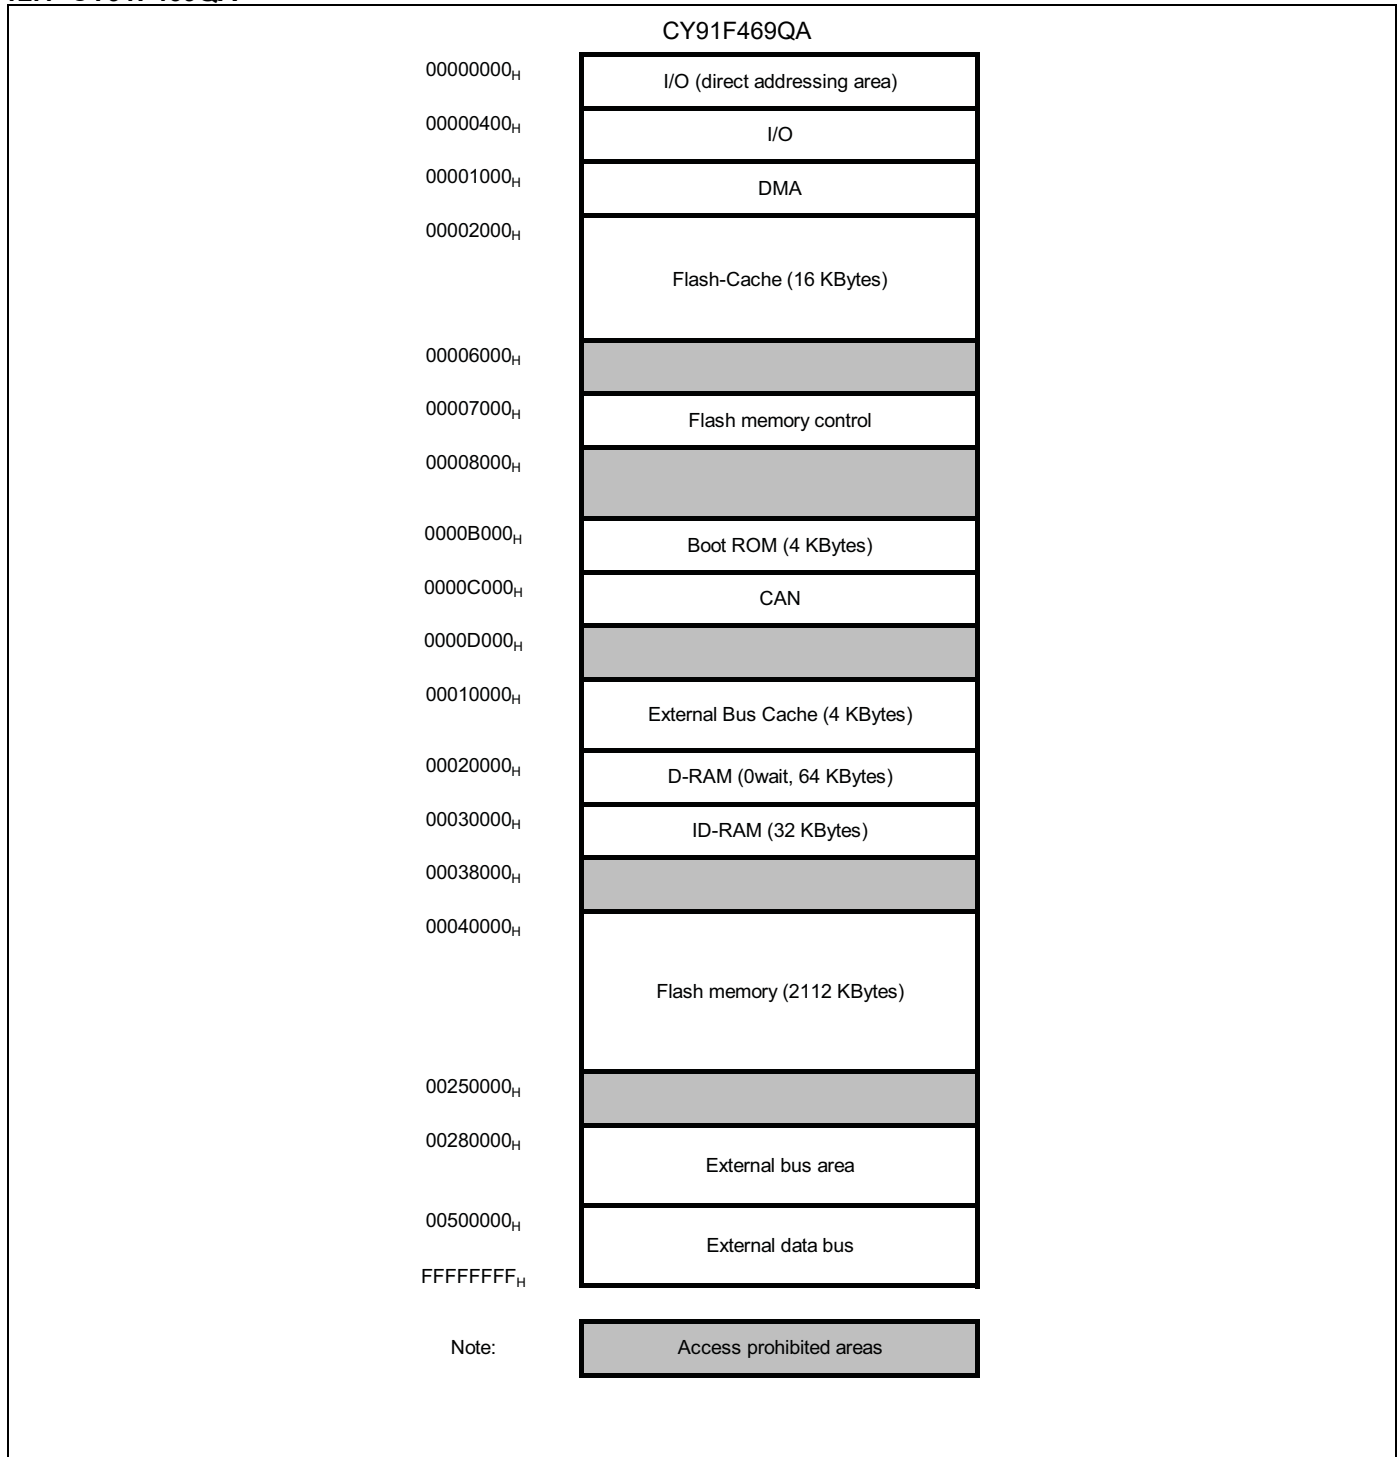

This area is called direct addressing area, and the address of an operand can be specified directly in an instruction.

The size of directly addressable area depends on the length of the data being accessed as shown below.

- Byte data access : 000<sub>H</sub> to 0FF<sub>H</sub>
- Half word access : 000<sub>H</sub> to 1FF<sub>H</sub>
- Word data access : 000<sub>H</sub> to 3FF<sub>H</sub>

\*1 : The Interrupt Control Registers (ICRs) are located in the interrupt controller and set the interrupt level for each interrupt request. An ICR is provided for each interrupt request.

\*2 : The vector address for each EIT (exception, interrupt or trap) is calculated by adding the listed offset to the table base register value (TBR) . The TBR specifies the top of the EIT vector table. The addresses listed in the table are for the default TBR value (000FFC00<sub>H</sub>) . The TBR is initialized to this value by a reset. The TBR is set to 000FFC00<sub>H</sub> after the internal boot ROM is executed.

\*3 : ICR23 and ICR47 can be exchanged by setting the REALOS compatibility bit (addr 0C03<sub>H</sub> : IOS[0])

\*4 : Used by REALOS

\*5 : Memory Protection Unit (MPU) support

## 15. Recommended Settings

### 15.1 PLL and Clockgear Settings

Please note that for CY91F469QA core base clock frequencies above 88MHz can only be achieved with 1.9V core supply voltage <sup>\*1</sup>.

Please see “Absolute Maximum Ratings” on page 96 to find the maximum allowed frequency of Core Base Clock (fCLKB) at high temperature.

## 15.2 Clock Modulator Settings

The following table shows all possible settings for the Clock Modulator in a base clock frequency range from 32MHz up to 88MHz. If Fmax exceeds 88MHz the core supply voltage needs to be set to 1.9V. Please refer to flash access time settings (section 2.3.2.2) to setup the correct voltage according to Fmax in the table below.

The Flash access time settings need to be adjusted according to Fmax while the PLL and clockgear settings should be set according to base clock frequency.

Please see “Absolute Maximum Ratings” on page 96 to find the maximum allowed frequency of Fmax (fCLKB) at high temperature.

\*1 : The parameter is based on  $V_{SS5} = AV_{SS5} = 0.0 \text{ V}$ .

\*2 :  $AV_{CC5}$  and  $AVRH5$  must not exceed  $V_{DD5} + 0.3 \text{ V}$ .

\*3 : • Use within recommended operating conditions.

- Use with DC voltage (current).
- +B signals are input signals that exceed the  $V_{DD5}$  voltage. +B signals should always be applied by connecting a limiting resistor between the +B signal and the microcontroller.
- The value of the limiting resistor should be set so that the current input to the microcontroller pin does not exceed the rated value at any time, either instantaneously or for an extended period, when the +B signal is input.
- Note that when the microcontroller drive current is low, such as in the low power consumption modes, the +B input potential can increase the potential at the power supply pin via a protective diode, possibly affecting other devices.
- Note that if the +B signal is input when the microcontroller is off (not fixed at 0 V), power is supplied through the +B input pin; therefore, the microcontroller may partially operate.
- Note that if the +B signal is input at power-on, since the power is supplied through the pin, the power-on reset may not function in the power supply voltage.

- Do not leave +B input pins open.
- Example of recommended circuit :

- \*4 : Maximum output current is defined as the value of the peak current flowing through any one of the corresponding pins.
- \*5 : Average output current is defined as the value of the average current flowing through any one of the corresponding pins for a 100 ms period.
- \*6 : Total average output current is defined as the value of the average current flowing through all of the corresponding pins for a 100 ms period.
- \*7 : The maximum permitted power dissipation depends on the ambient temperature, the air flow velocity and the thermal conductance of the package on the PCB.  
The actual power dissipation depends on the customer application and can be calculated as follows:  

$$P_D = P_{IO} + P_{INT}$$

$$P_{IO} = \sum (|V_{SS}-V_{OL}| * I_{OL} + |V_{DD}-V_{OH}| * I_{OH})$$
 (IO load power dissipation, sum is performed on all IO ports)  

$$P_{INT} = V_{DD}5R * I_{CC} + AV_{CC}5 * I_A + AVRH5 * I_R$$
 (internal power dissipation)
- \*8 : Worst case value for the BGA package mounted on a 4-layer PCB at specified  $T_A$  without air flow.
- \*9 : Please contact Fujitsu's representative for reliability limitations when using under these conditions.
- \*10: Applicable only for devices with  $T_{A(max)} \geq T_A$ .

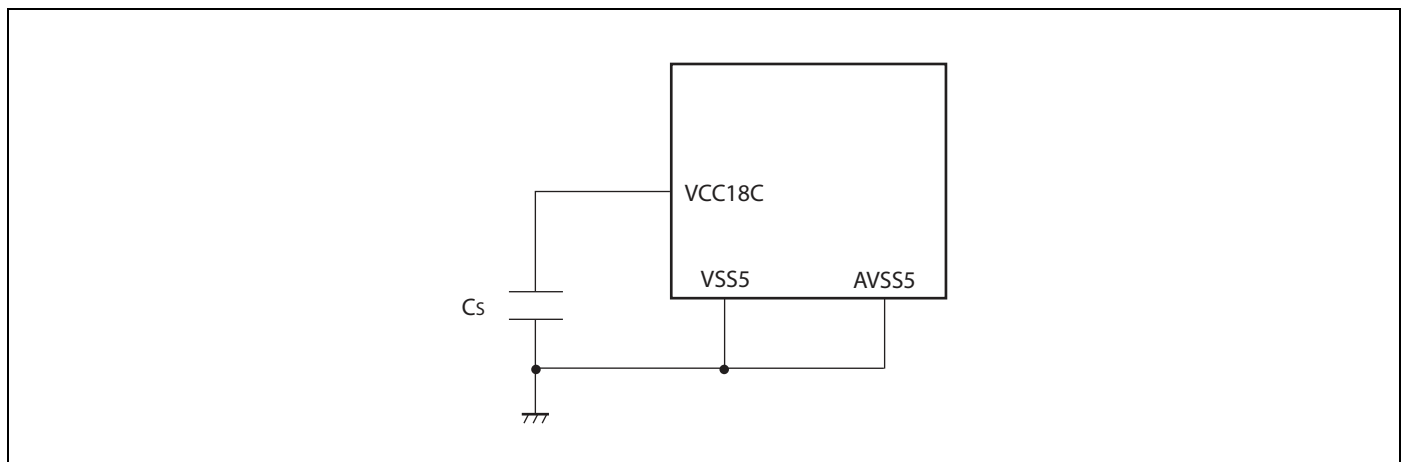

**WARNING:** Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their representatives beforehand.

#### Definition of A/D Converter Terms

- Resolution  
Analog variation that is recognizable by the A/D converter.
- Nonlinearity error  
Deviation between actual conversion characteristics and a straight line connecting the zero transition point ( $00\ 0000\ 0000_B \leftrightarrow 00\ 0000\ 0001_B$ ) and the full scale transition point ( $11\ 1111\ 1110_B \leftrightarrow 11\ 1111\ 1111_B$ ).
- Differential nonlinearity error  
Deviation of the input voltage from the ideal value that is required to change the output code by 1 LSB.
- Total error  
This error indicates the difference between actual and theoretical values, including the zero transition error, full scale transition error, and nonlinearity error.

$$1\text{LSB}' (\text{ideal value}) = \frac{\text{AVRH} - \text{AV}_{\text{SS}5}}{1024} \text{ [V]}$$

$$\text{Nonlinearity error of digital output } N = \frac{V_{NT} - \{1\text{LSB} \times (N - 1) + V_{OT}\}}{1\text{LSB}} \text{ [LSB]}$$

$$\text{Differential nonlinearity error of digital output } N = \frac{V_{(N+1)T} - V_{NT}}{1\text{LSB}} - 1 \text{ [LSB]}$$

$$1\text{LSB} = \frac{V_{FST} - V_{OT}}{1022} \text{ [V]}$$

N : A/D converter digital output value

V<sub>OT</sub> : Voltage at which the digital output changes from 000<sub>H</sub> to 001<sub>H</sub>.
