

General Description

The MIC2289 is a PWM (pulse width modulated), boost-switching regulator that is optimized for constant-current white LED driver applications. The MIC2289 features an internal Schottky diode and three levels of output overvoltage protection providing a small size and efficient DC/DC solution that requires only four external components.

To optimize efficiency, the feedback voltage is set to only 95mV. This reduces power dissipation in the current set resistor and allows the lowest total output voltage, hence minimal current draw from the battery.

The MIC2289 implements a constant frequency 1.2MHz PWM control scheme. The high frequency, PWM operation saves board space by reducing external component sizes. The added benefit of the constant frequency PWM scheme in comparison to variable frequency is much lower noise and input ripple injected to the input power source.

The MIC2289 clamps the output voltage in case of open LED conditions, protecting itself and the output capacitor. The MIC2289 is available with three output OVP options of 15V, 24V, and 34V. The different OVP options allows the use of the smallest possible output capacitor with the appropriate voltage rating for a given application.

The MIC2289 is available in low profile 6-pin Thin SOT-23 and 8-pin 2mm × 2mm MLF[®] package options. The MIC2289 has a junction temperature range of -40°C to +125°C.

Data sheets and support documentation can be found on Micrel's web site at: www.micrel.com.

Features

- 2.5V to 10V input voltage
- Output voltage up to 34V
- Internal Schottky diode
- 15V, 24V, 34V output OVP options
- 1.2 MHz PWM operation
- Over 500mA switch current
- 95mV feedback voltage
- <1% line and load regulation
- <1µA shutdown current
- Overtemperature protection
- UVLO
- 2mm × 2mm 8-pin MLF[®] package
- -40°C to +125°C junction temperature range

Applications

- White LED driver for backlighting:
 - Cell phones
 - PDAs
 - GPS systems
 - Digital cameras
 - MP3 players
 - IP phones
- LED flashlights
- Constant current power supplies

Typical Application

3-Series White LED Driver

Pin Description

| Pin Number TSOT-23-6 | Pin Number MLF [®] -8 | Pin Name | Pin Name |
|-------------------------|-----------------------------------|----------|---|
| 1 | 7 | SW | Switch node (Input): Internal power BIPOLAR collector. |
| 2 | — | GND | Ground (Return): Ground. |
| 3 | 6 | FB | Feedback (Input): Output voltage sense node. Connect the cathode of the LED to this pin. A resistor from this pin to ground sets the LED current. |
| 4 | 3 | EN | Enable (Input): Logic high enables regulator. Logic low shuts down regulator. |
| 5 | 2 | VIN | Supply (Input): 2.7V to 8V for internal circuitry. |
| 6 | 1 | VOUT | Output Pin and Overshoot Protection (Output): Connect to the output capacitor and LEDs. |
| — | 4 | AGND | Analog ground. |
| — | 8 | PGND | Power ground. |
| — | 5 | NC | No connect (no internal connection to die). |
| — | EP | GND | Ground (Return): Exposed backside pad. |

Notes:

- Absolute maximum ratings indicate limits beyond which damage to the component may occur. Electrical specifications do not apply when operating the device outside of its operating ratings. The maximum allowable power dissipation is a function of the maximum junction temperature, $T_{J(max)}$, the junction-to-ambient thermal resistance, θ_{JA} , and the ambient temperature, T_A . The maximum allowable power dissipation will result in excessive die temperature, and the regulator will go into thermal shutdown.
- The device is not guaranteed to function outside its operating rating.
- Devices are ESD sensitive. Handling precautions recommended. Human body model.
- Specification for packaged product only.
- $I_{SD} = I_{VIN}$.
- Guaranteed by design

Typical Characteristics

Functional Diagram

MIC2289 Block Diagram

Functional Description

The MIC2289 is a constant frequency, PWM current mode boost regulator. The block diagram is shown above. The MIC2289 is composed of an oscillator, slope compensation ramp generator, current amplifier, g_m error amplifier, PWM generator, 500mA bipolar output transistor, and Schottky rectifier diode. The oscillator generates a 1.2MHz clock. The clock's two functions are to trigger the PWM generator that turns on the output transistor and to reset the slope compensation ramp generator. The current amplifier is used to measure the switch current by amplifying the voltage signal from the internal sense resistor. The output of the current amplifier is summed with the output of the slope compensation ramp generator. This summed current-loop signal is fed to one of the inputs of the PWM generator.

The g_m error amplifier measures the LED current through the external sense resistor and amplifies the error between the detected signal and the 95mV reference voltage. The output of the g_m error amplifier provides the voltage-loop signal that is fed to the other input of the PWM generator. When the current-loop signal exceeds the voltage-loop signal, the PWM generator turns off the bipolar output transistor. The next clock period initiates the next switching cycle, maintaining the constant frequency current-mode PWM control. The LED is set by the feedback resistor:

$$I_{LED} = \frac{95mV}{R_{FB}}$$

The Enable pin shuts down the output switching and disables control circuitry to reduce input current-to-leakage levels. Enable pin input current is zero at zero volts.

External Component Selection

inductor and output capacitor values for various series-LED applications.

The MIC2289 can be used across a wide range of applications. The table below shows recommended

| Series LEDs | L | Manufacturer | Min C _{OUT} | Manufacturer | |

Dimming Control

There are two techniques for dimming control. One is PWM dimming, and the other is continuous dimming.

1. PWM dimming control is implemented by applying a PWM signal on EN pin as shown in Figure 1. The MIC2289 is turned on and off by the PWM signal. With this method, the LEDs operate with either zero or full current. The average LED current is increased proportionally to the duty-cycle of the PWM signal. This technique has high-efficiency because the IC and the LEDs consume no current during the off cycle of the PWM signal. Typical frequency should be between 100Hz and 10kHz.
2. Continuous dimming control is implemented by applying a DC control voltage to the FB pin of the MIC2289 through a series resistor as shown in Figure 2. The LED current is decreased proportionally with the amplitude of the control voltage. The LED intensity (current) can be dynamically varied applying a DC voltage to the FB pin. The DC voltage can come from a DAC signal, or a filtered PWM signal. The advantage of this approach is that a high frequency PWM signal (>10kHz) can be used to control LED intensity.

Figure 1. PWM Dimming Method

Figure 2. Continuous Dimming

Open-Circuit Protection

If the LEDs are disconnected from the circuit, or in case an LED fails open, the sense resistor will pull the FB pin to ground. This will cause the MIC2289 to switch with a high duty-cycle, resulting in output overvoltage. This may cause the SW pin voltage to exceed its maximum voltage rating, possibly damaging the IC and the external components. To ensure the highest level of protection, the MIC2289 has 3 product options in the 2mm × 2mm MLF[®]-8 with overvoltage protection, OVP. The extra pins of the 2mm × 2mm MLF[®]-8 package allow a dedicated OVP monitor with options for 15V, 24V, or 34V (see Figure 3). The reason for the three OVP levels is to let users choose the suitable level of OVP for their application. For example, a 3-LED application would typically see an output voltage of no more than 12V, so a 15V OVP option would offer a suitable level of protection. This allows the user to select the output diode and capacitor with the lowest voltage ratings, therefore smallest size and lowest cost. The OVP will clamp the output voltage to within the specified limits.

Figure 3. OVP Circuit

Start-Up and Inrush Current

During start-up, inrush current of approximately double the nominal current flows to set up the inductor current and the voltage on the output capacitor. If the inrush current needs to be limited, a soft-start circuit similar to Figure 4 could be implemented. The soft-start capacitor, CSS, provides over-drive to the FB pin at start-up, resulting in gradual increase of switch duty cycle and limited inrush current.
