

Smart LED Lamp Driver IC with PFC Function

FL7701

SOIC8
CASE 751EB

Description

The FL7701 LED lamp driver is a simple IC with PFC function. The special “adopted digital” technique of the IC can automatically detect input voltage condition and send an internal reference signal for achieving high power factor. When AC input is applied to the IC, PFC function is automatically enabled. Otherwise, when DC input is applied to the IC, PFC function is automatically disabled. The FL7701 does not need a bulk capacitor (electrolytic capacitor) for supply rail stability, which can significantly affect to LED lamp system.

Features

- Digitally Implemented Active PFC Function (No Additional Circuit Necessary for High PF)
- Built-in HV Supplying Circuit: Self Biasing
- Application Input Range: 80 V_{AC}~308 V_{AC}
- AOCF Function with Auto-Restart Mode
- Built-in Over-Temperature Protection Function
- Cycle-by-Cycle Current Limit
- Current-Sense Pin Open Protection
- Low Operating Current: 0.85 mA (Typical)
- Under-Voltage Lockout with 5 V Hysteresis
- Programmable Oscillation Frequency
- Programmable LED Current
- Analog Dimming Function
- Soft-Start Function
- Precise Internal Reference: ±3%

Applications

- LED Lamp for Decorative Lighting
- LED Lamp for Low-Power Lighting

PIN CONFIGURATION

Figure 3. Pin Configuration

PIN DEFINITIONS

Pin No.	Name	Description
1	CS	<i>Current Sense.</i> Limits output current depending on the sensing resistor voltage. The CS pin is also used to set the LED current regulation
2	OUT	<i>OUT.</i> Connects to the MOSFET gate.
3	VCC	<i>VCC.</i> Supply pin for stable IC operation ZCD signal detection used for accurate PFC function.
4	RT	<i>RT.</i> Programmable operating frequency using external resistor and the IC has pre-fixed frequency when this pin is open or floating.
5	ADIM	<i>Analog Dimming.</i> Connect to the internal current source and can change the output current using an external resistor. If ADIM is not used, it is recommended to connect a 0.1 μ F bypass capacitor between the ADIM and GND.
6	GND	<i>GROUND.</i> Ground for the IC.
7	NC	No Connection
8	HV	<i>High Voltage.</i> Connect to the high voltage line and supply current to the IC

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Min	Max	Unit	
V _{CC}	IC Supply Voltage	-	20	V	
HV	High Voltage Sensing	-	500	V	
I _{O+} /I _{O-}	Peak Drive Output Current (Sourcing / Sinking)	-	250	mA	
V _{ADIM}	Analog Dimming	-	5	V	
V _{RT}	RT Pin Voltage	-	5	V	
V _{CS}	Allowable Current Sensing Detection Voltage	-	5	V	
T _A	Operating Ambient Temperature Range	-40	+125	°C	
T _J	Operating Junction Temperature	-40	+150	°C	
T _{STG}	Storage Temperature Range	-65	+150	°C	
θ_{JA}	Thermal Resistance Junction-Air (Notes 1, 2)	-	135	°C/W	
P _D	Power Dissipation	-	660	mW	
ESD	Electrostatic Discharge Capability	Human Body Model, JESD22-A114	-	2000	V
		Charged Device Model, JESD22-C101	-	1000	

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. Thermal resistance test board. Size: 76.2 mm x 114.3 mm x 1.6 mm (1S0P); JEDEC standard: JESD51-2, JESD51-3.
2. Assume no ambient airflow.

Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

3. These parameters, although guaranteed, are not 100% tested in production.

FUNCTIONAL DESCRIPTION

The FL7701 is a basic PWM controller for buck converter topology in Continuous Conduction Mode (CCM) with intelligent PFC function using a digital control algorithm. The FL7701 has an internal self-biasing circuit that uses the high-voltage switching device. The IC does not need an auxiliary powering path to the VCC pin typical in flyback control ICs or PSR product family.

When the input voltage applied to the HV pin is over 25 V to 500 V, the FL7701 maintains a 15.5 V DC voltage at the VCC pin for stable operation. The FL7701 has UVLO block functions such that when the VCC voltage rises higher than V_{CCST+} , the internal UVLO block releases and starts operation. Otherwise the VCC goes down to the V_{CCST-} and IC operation stops. Normally, the hysteresis function provides stable operation even if the input voltage is operating under the very noisy or unstable circumstances.

The FL7701 has a smart internal digital block for determining input condition: AC or DC. When an AC source with 50 Hz or 60 Hz is applied to the IC, the IC automatically changes its internal reference signal, which is similar to input signal, for creating high power factor. Otherwise, once the DC source connects to the IC, the internal reference immediately changes to DC.

Soft-Start Function

The FL7701 has an internal soft-start function to reduce inrush current at startup. When the IC starts operation following an internal sequence, the internal reference slowly increases for a pre-determined fixed time. After this transient period, the internal reference goes to a steady-state level. In this time, the IC continually tries to find phase information from the VCC pin. If the IC succeeds in getting phase information, it automatically follows a similar shape reference made during the transient times, 7 periods. If not, the IC has a DC reference level.

Figure 4. Soft Starting Function in AC Input Mode

Internal PFC Function: How to Achieve High Power Factor

The FL7701 has a simple, but smart, internal PFC function that does not require additional detection pins for detecting input phase information or an electrolytic capacitor for supply voltage stabilization. For achieving high PF, the FL7701 does not use the rectification capacitor after the bridge diode. This is important because the IC

instead uses fluctuation in the signal on the VCC pin. Basically, the VCC pin, which supplies power for the IC, has voltage ripple as well as the rectification voltage after bridge, changing voltage level according to the VCC capacitor value. Using this kind of voltage fluctuation on the VCC pin, the IC can detect the time reference and create the internal ZCD signal.

For precise and reliable internal reference for input voltage signal, the FL7701 uses a digital technique (sigma/delta modulation) and creates a new internal signal (DAC_OUT) that has the same phase as the input voltage, as shown in Figure 5. This signal enters the final comparator and is compared with current information from the sensing resistor.

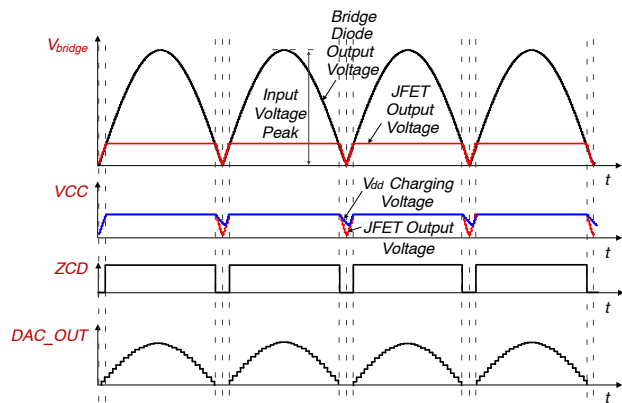

Figure 5. Internal PFC Function

Self-Biasing Function

The self-biasing function, using an HV device, can supply enough operating current to the IC and guarantee similar startup time across the whole input voltage range (80 V~308 V_{AC}). However, self-biasing has a weakness in high-voltage condition. Normally, the HV device acts as constant current source, so the internal HV device has power loss when high input voltage connects to the HV pin. This power loss is proportional to input voltage. To reduce this power loss, one of the possible solutions is an additional resistor between the input voltage source and the HV pin, as shown in Figure 6.

Figure 6. High-Voltage Application

Dimming Function

The FL7701 uses the ADIM pin for analog or 0 V to 10 V dimming by using a resistive divider. The peak voltage of internal reference, which is DAC_OUT signal in Figure 5, is changed by the V_{ADIM} level, as shown in Figure 7, and has different peak level according to the operating mode.

Figure 7. V_{ADIM} vs. V_{DAC_OUT(peak)}

Inductor Design

The FL7701 prefixed internal duty ratio range is below 50%, or around 400 ns, from timing point of view. The range is dependent on the input voltage and LED numbers in its string.

Minimum duty is calculated as:

$$D_{min} = \frac{n \cdot V_f}{\eta \cdot V_{in(max)}} \quad (eq. 1)$$

where:

η is efficiency of system;

$V_{IN(max)}$ is maximum input voltage;

V_f is forward drop voltage of LED; and

n is LED number in series connection.

Figure 8. DCM and CCM Operation

In DCM Mode, inductance is:

$$L_m = \frac{n \cdot V_f \cdot (1 - D_{min})}{f_s \cdot \Delta i_{rip}} \quad [H] \quad (eq. 2)$$

If the peak current is fixed at 350 mApk, the formula for the peak current is:

$$I_{LED(ave,peak)} = \Delta i_{con} + \frac{\Delta i_{rip}}{2} \quad [A] \quad (eq. 3)$$

In FL7701, the LED RMS current determines the inductance parameter. To drive for CCM Mode, define LED RMS current first, as:

$$I_{LED(rms)} = \frac{I_{LED(ave,peak)}}{\sqrt{2}} \quad [A] \quad (eq. 4)$$

Substituting Equation (2) for Equation (4), the inductance of inductor is obtained.
