

# TPS54040-Q1 0.5-A 42-V Step-Down DC-DC Converter With Eco-Mode™

## 1 Features

- Qualified for Automotive Applications
- 3.5-V to 42-V Input Voltage Range
- 200-mΩ High-Side MOSFET
- High Efficiency at Light Loads with a Pulse Skipping Eco-Mode™ Control Scheme
- 116-μA Operating Quiescent Current
- 1.3-μA Shutdown Current
- 100-kHz to 2.5-MHz Switching Frequency
- Synchronizes to External Clock
- Adjustable Slow Start and Sequencing
- Undervoltage and Overvoltage Power-good Output
- Adjustable Undervoltage Lockout Voltage and Hysteresis
- 0.8-V Internal Voltage Reference
- Supported by SwitcherPro™ Software Tool (<http://focus.ti.com/docs/toolsw/folders/print/switcherpro.html>)

## 2 Applications

- 12-V and 24-V Industrial and Commercial Low Power Systems
- Automotive Infotainment, Head Unit, Display Navigation, Audio and Clusters
- Automotive Body applications, HVAC, Wireless Charging
- Advanced Driver Assistance System (ADAS), Rear View Camera Module, Blind Spot Radar

## 3 Description

The TPS54040-Q1 device is a 42-V 0.5-A step-down regulator with an integrated high-side MOSFET. Current mode control provides simple external compensation and flexible component selection. A low-ripple pulse-skip mode reduces the no load, input supply current to 116 μA. Using the enable pin, shutdown supply current is reduced to 1.3 μA, when the enable pin is low.

Undervoltage lockout is internally set at 2.5 V, but can be increased using the enable pin. The output voltage startup ramp is controlled by the slow start pin that can also be configured for sequencing or tracking. An open drain power-good signal indicates the output is within 92% to 109% of its nominal voltage.

A wide switching frequency range allows efficiency and external component size to be optimized. Frequency fold back and thermal shutdown protects the part during an overload condition.

The TPS54040-Q1 is available in a 10-pin thermally enhanced MSOP PowerPAD™ package (DGQ) and a 10-pin SON package (DRC).

### Device Information<sup>(1)</sup>

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TPS54040-Q1	MSOP PowerPAD (10)	3.00 mm × 3.00 mm
	VSON (10)	3.00 mm × 3.00 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

## 4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

<b>Changes from Revision D (June 2012) to Revision E</b>	<b>Page</b>
• Added <i>ESD Ratings</i> table, <i>Feature Description</i> section, <i>Device Functional Modes</i> , <i>Application and Implementation</i> section, <i>Power Supply Recommendations</i> section, <i>Layout</i> section, <i>Device and Documentation Support</i> section, and <i>Mechanical, Packaging, and Orderable Information</i> section .....	1
• Moved "Operating junction temperature row" from <i>Absolute Maximum Ratings</i> to <i>Recommended Operating Conditions</i> .....	4
• Changed title "How to Interface to RT/CLK Pin" to External Clock Synchronization Using RT/CLK Pin .....	23
• Deleted Capacitor Types table .....	34

<b>Changes from Revision C (January 2012) to Revision D</b>	<b>Page</b>
• Changed "regulated output supply current" to "input supply current".....	1
• Changed 107% to 109% in description .....	1
• Added (fault) and (good) to VSENSE rising and falling.....	6
• Changed "UVLO adjust registers" to "UVLO adjust resistors" .....	14
• Removed "and the power pad", changed power pad to PowerPAD where applicable .....	39

## 5 Pin Configuration and Functions

### Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
BOOT	1	O	A bootstrap capacitor is required between BOOT and PH. If the voltage on this capacitor is below the minimum required by the output device, the output is forced to switch off until the capacitor is refreshed.
COMP	8	O	Error amplifier output, and input to the output switch current comparator. Connect frequency compensation components to this pin.
EN	3	I	Enable pin, internal pull-up current source. Pull below 1.2 V to disable. Float to enable. Adjust the input undervoltage lockout with two resistors.
GND	9	–	Ground
PH	10	I	The source of the internal high-side power MOSFET.
PWRGD	6	O	An open drain output, asserts low if output voltage is low due to thermal shutdown, dropout, over-voltage or EN shut down.
RT/CLK	5	I	Resistor Timing and External Clock. An internal amplifier holds this pin at a fixed voltage when using an external resistor to ground to set the switching frequency. If the pin is pulled above the PLL upper threshold, a mode change occurs and the pin becomes a synchronization input. The internal amplifier is disabled and the pin is a high impedance clock input to the internal PLL. If clocking edges stop, the internal amplifier is re-enabled and the mode returns to a resistor set function.
SS/TR	4	I	Slow-start and Tracking. An external capacitor connected to this pin sets the output rise time. Since the voltage on this pin overrides the internal reference, it can be used for tracking and sequencing.
VIN	2	I	Input supply voltage, 3.5 V to 42 V.
VSENSE	7	I	Inverting node of the transconductance ( gm ) error amplifier.
Thermal Pad	11	–	GND pin must be electrically connected to the exposed pad on the printed circuit board for proper operation.

## 6 Specifications

### 6.1 Absolute Maximum Ratings

 over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

		MIN	MAX	UNIT	
Input voltage	VIN	-0.3	47	V	
	EN <sup>(2)</sup>	-0.3	5		
	BOOT		55		
	VSENSE	-0.3	3		
	COMP	-0.3	3		
	PWRGD	-0.3	6		
	SS/TR	-0.3	3		
	RT/CLK	-0.3	3.6		
Output voltage	BOOT-PH		8	V	
	PH	DC Voltage	-0.6		47
		200 ns Transient Pulse	-1		47
		30 ns Transient Pulse	-2		47
	DC voltage, T <sub>J</sub> = -40°C	-0.85			
Voltage difference	PAD to GND		±200	mV	
Source current	EN		100	µA	
	BOOT		100	mA	
	VSENSE		10	µA	
	PH		Current Limit		
	RT/CLK		100	µA	
Sink current	VIN		Current Limit		
	COMP		100	µA	
	PWRGD		10	mA	
	SS/TR		200	µA	
Storage temperature		-65	150	°C	

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) See [Enable and Adjusting Undervoltage Lockout](#) for details.

### 6.2 ESD Ratings

		VALUE	UNIT
V <sub>(ESD)</sub>	Electrostatic discharge	Human body model (HBM), per AEC Q100-002 <sup>(1)</sup>	±500
		Charged-device model (CDM), per AEC Q100-011	±1000

- (1) AEC Q100-002 indicates that HBM stressing shall be in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

### 6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	NOM	MAX	UNIT
VIN supply voltage	3.5		42	V
Output current capability			0.5	A
Output voltage range for adjustable voltage	0.8		VIN	V
Effective input capacitance	3			µF
Operating junction temperature, T <sub>J</sub>	-40		150	°C

## 6.4 Thermal Information

THERMAL METRIC <sup>(1)(2)</sup>		TPS54040-Q1		UNIT
		DGQ (HVSSOP)	DRC (VSON)	
		10 PINS	10 PINS	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance (standard board)	62.5	56.5	°C/W
R <sub>θJA</sub>	Junction-to-case (top) thermal resistance	83	52.1	°C/W
R <sub>θJC(top)</sub>	Junction-to-ambient thermal resistance (custom board) <sup>(3)</sup>	57	61.5	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	28	20.6	°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	1.7	0.9	°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	20.1	20.8	°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	21	5.2	°C/W

- (1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, [SPRA953](#).
- (2) Power rating at a specific ambient temperature T<sub>A</sub> should be determined with a junction temperature of 150°C. This is the point where distortion starts to substantially increase. See power dissipation estimate in application section of this data sheet for more information.
- (3) Test boards conditions:
  - (a) 3 inches x 3 inches, 2 layers, thickness: 0.062 inch
  - (b) 2 oz. copper traces located on the top of the PCB
  - (c) 2 oz. copper ground plane, bottom layer
  - (d) 6 thermal vias (13 mil) located under the device package

## 6.5 Electrical Characteristics

T<sub>J</sub> = –40°C to 150°C, V<sub>IN</sub> = 3.5 to 42 V (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>SUPPLY VOLTAGE (VIN PIN)</b>					
Operating input voltage		3.5		42	V
Internal undervoltage lockout threshold	No voltage hysteresis, rising and falling		2.5		V
Shutdown supply current	EN = 0 V, 25°C, 3.5 V ≤ V <sub>IN</sub> ≤ 42 V		1.3	4	μA
	EN = 0 V, 125°C, 3.5 V ≤ V <sub>IN</sub> ≤ 42 V		1.9	6.5	
Operating : nonswitching supply current	V <sub>SENSE</sub> = 0.83 V, V <sub>IN</sub> = 12 V, 25°C		116	136

## 7 Detailed Description

### 7.1 Overview

The TPS54040-Q1 device is a 42-V, 0.5-A, step-down (buck) regulator with an integrated high-side N-channel MOSFET. To improve performance during line and load transients the device implements a constant frequency, current mode control which reduces output capacitance and simplifies external frequency compensation design. The wide switching frequency of 100 kHz to 2500 kHz allows for efficiency and size optimization when selecting the output filter components. The switching frequency is adjusted using a resistor to ground on the RT/CLK pin. The device has an internal phase lock loop (PLL) on the RT/CLK pin that is used to synchronize the power switch turn on to a falling edge of an external system clock.

The EN pin of TPS54040-Q1 has an internal pull-up current source to  $V_{in}$  and with EN pin floating, device will turn on when input voltage reaches approximately 2.5 V. But this undervoltage lockout (UVLO) threshold can be adjusted with external voltage divider resistors connected to input voltage. The operating current is 116  $\mu$ A when not switching and under no load. When the device is disabled, the supply current is 1.3  $\mu$ A.

The integrated 200-m $\Omega$  high-side MOSFET allows for high efficiency power supply designs capable of delivering 0.5 amperes of continuous current to a load. The TPS54040-Q1 reduces the external component count by integrating the boot recharge diode. The bias voltage for the integrated high-side MOSFET is supplied by a capacitor on the BOOT to PH pin. The boot capacitor voltage is monitored by an UVLO circuit and will turn the high-side MOSFET off when the boot voltage falls below a preset threshold. The TPS54040-Q1 can operate at high duty cycles because of the boot UVLO. The output voltage can be stepped down to as low as the 0.8-V reference.

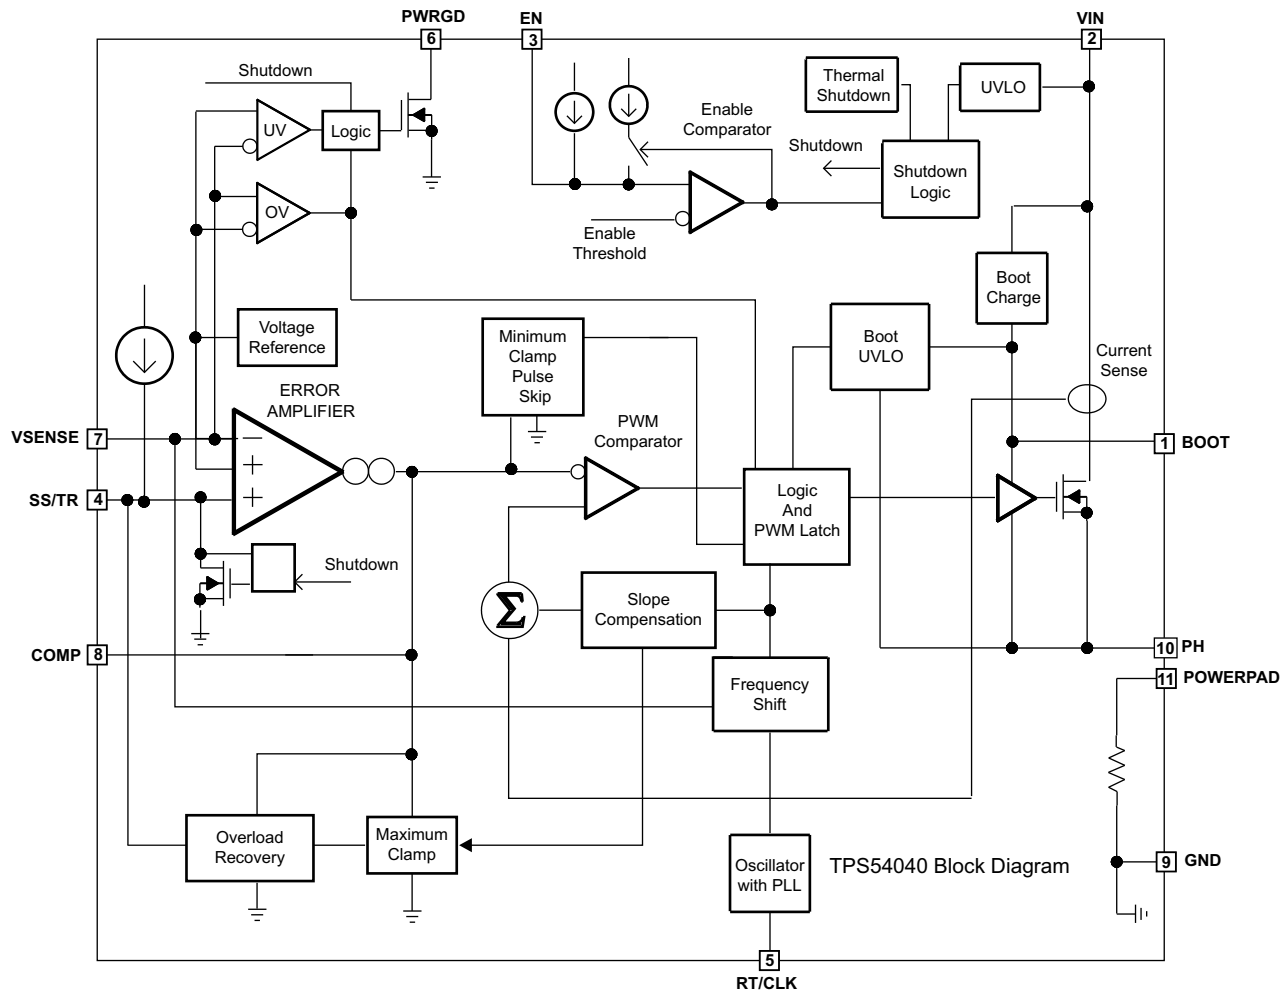

The TPS54040-Q1 has a power-good comparator (PWRGD) which asserts when the regulated output voltage is less than 92% or greater than 109% of the nominal output voltage. The PWRGD pin is an open drain output which deasserts when the VSENSE pin voltage is between 94% and 107% of the nominal output voltage allowing the pin to transition high when a pull-up resistor is used.

The TPS54040-Q1 minimizes excessive output overvoltage (OV) transients by taking advantage of the OV power-good comparator. When the OV comparator is activated, the high-side MOSFET is turned off and masked from turning on until the output voltage is lower than 107%.

The SS/TR (slow start/tracking) pin is used to minimize inrush currents or provide power supply sequencing during power up. A small value capacitor should be coupled to the pin to adjust the slow start time. A resistor divider can be coupled to the pin for critical power supply sequencing requirements. The SS/TR pin is discharged before the output powers up. This discharging ensures a repeatable restart after an overtemperature fault, UVLO fault or a disabled condition.

The TPS54040-Q1 discharges the slow start capacitor during overload conditions with an overload recovery circuit. The overload recovery circuit will slow start the output from the fault voltage to the nominal regulation voltage once a fault condition is removed. A frequency foldback circuit reduces the switching frequency during startup and overcurrent fault conditions to help control the inductor current.

## 7.2 Functional Block Diagram

## 7.3 Feature Description

### 7.3.1 Fixed Frequency PWM Control

The TPS54040-Q1 uses an adjustable fixed frequency, peak current mode control. The output voltage is compared through external resistors on the VSENSE pin to an internal voltage reference by an error amplifier which drives the COMP pin. An internal oscillator initiates the turn on of the high-side power switch. The error amplifier output is compared to the high-side power switch current. When the power switch current reaches the level set by the COMP voltage, the power switch is turned off. The COMP pin voltage will increase and decrease as the output current increases and decreases. The device implements a current limit by clamping the COMP pin voltage to a maximum level. The Eco-Mode is implemented with a minimum clamp on the COMP pin.

### 7.3.2 Slope Compensation Output Current

The TPS54040-Q1 adds a compensating ramp to the switch current signal. This slope compensation prevents sub-harmonic oscillations. The available peak inductor current remains constant over the full duty cycle range.

### 7.3.3 Low Dropout Operation and Bootstrap Voltage (BOOT)

The TPS54040-Q1 has an integrated boot regulator, and requires a small ceramic capacitor between the BOOT and PH pins to provide the gate drive voltage for the high-side MOSFET. The BOOT capacitor is refreshed when the high-side MOSFET is off and the low-side diode conducts. The value of this ceramic capacitor should be 0.1  $\mu\text{F}$ . A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating of 10 V or higher is recommended because of the stable characteristics over temperature and voltage.

## Feature Description (continued)

To improve drop out, the TPS54040-Q1 is designed to operate at 100% duty cycle as long as the BOOT to PH pin voltage is greater than 2.1 V. When the voltage from BOOT to PH drops below 2.1 V, the high-side MOSFET is turned off using an UVLO circuit which allows the low-side diode to conduct and refresh the charge on the BOOT capacitor. Since the supply current sourced from the BOOT capacitor is low, the high-side MOSFET can remain on for more switching cycles than are required to refresh the capacitor, thus the effective duty cycle of the switching regulator is high.

The effective duty cycle during dropout of the regulator is mainly influenced by the voltage drops across the power MOSFET, inductor resistance, low-side diode and printed-circuit-board resistance. During operating conditions in which the input voltage drops and the regulator is operating in continuous conduction mode, the high-side MOSFET can remain on for 100% of the duty cycle to maintain output regulation, until the BOOT to PH voltage falls below 2.1 V.

Attention must be taken in maximum duty cycle applications which experience extended time periods with light loads or no load. When the voltage across the BOOT capacitor falls below the 2.1-V UVLO threshold, the high-side MOSFET is turned off, but there may not be enough inductor current to pull the PH pin down to recharge the BOOT capacitor. The high-side MOSFET of the regulator stops switching because the voltage across the BOOT capacitor is less than 2.1 V. The output capacitor then decays until the difference in the input voltage and output voltage is greater than 2.1 V, at which point the BOOT UVLO threshold is exceeded, and the device starts switching again until the desired output voltage is reached. This operating condition persists until the input voltage and/or the load current increases. It is recommended to adjust the VIN stop voltage greater than the BOOT UVLO trigger condition at the minimum load of the application using the adjustable VIN UVLO feature with resistors on the EN pin.

The start and stop voltages for typical 3.3-V and 5-V output applications are shown in [Figure 25](#) and [Figure 26](#). The voltages are plotted versus load current. The start voltage is defined as the input voltage needed to regulate the output within 1%. The stop voltage is defined as the input voltage at which the output drops by 5% or stops switching.

During high duty cycle conditions, the inductor current ripple increases while the BOOT capacitor is being recharged resulting in an increase in ripple voltage on the output. This is due to the recharge time of the boot capacitor being longer than the typical high-side OFF-time when switching occurs every cycle.

## Feature Description (continued)

### 7.3.4 Error Amplifier

The TPS54040-Q1 has a transconductance amplifier for the error amplifier. The error amplifier compares the VSENSE voltage to the lower of the SS/TR pin voltage or the internal 0.8-V voltage reference. The transconductance (gm) of the error amplifier is 97  $\mu\text{A}/\text{V}$  during normal operation. During the slow start operation, the transconductance is a fraction of the normal operating gm. When the voltage of the VSENSE pin is below 0.8 V and the device is regulating using the SS/TR voltage, the gm is 25  $\mu\text{A}/\text{V}$ .

The frequency compensation components (capacitor, series resistor and capacitor) are added to the COMP pin to ground.

### 7.3.5 Voltage Reference

The voltage reference system produces a precise  $\pm 2\%$  voltage reference over temperature by scaling the output of a temperature stable bandgap circuit.

### 7.3.6 Adjusting the Output Voltage

The output voltage is set with a resistor divider from the output node to the VSENSE pin. It is recommended to use 1% tolerance or better divider resistors. Start with a 10 k $\Omega$  for the R2 resistor and use the Equation 1 to calculate R1. To improve efficiency at light loads consider using larger value resistors. If the values are too high the regulator will be more susceptible to noise and voltage errors from the VSENSE input current will be noticeable

$$R1 = R2 \times \left( \frac{V_{\text{out}} - 0.8\text{V}}{0.8\text{V}} \right) \quad (1)$$

### 7.3.7 Enable and Adjusting Undervoltage Lockout

The TPS54040-Q1 is disabled when the VIN pin voltage falls below 2.5 V. If an application requires a higher undervoltage lockout (UVLO), use the EN pin as shown in Figure 27 to adjust the input voltage UVLO by using the two external resistors. Though it is not necessary to use the UVLO adjust resistors, for operation it is highly recommended to provide consistent power up behavior. The EN pin has an internal pull-up current source, I1, of 0.9  $\mu\text{A}$  that provides the default condition of the TPS54040-Q1 operating when the EN pin floats. Once the EN pin voltage exceeds 1.25 V, an additional 2.9  $\mu\text{A}$  of hysteresis, I<sub>HYS</sub>, is added. This additional current facilitates input voltage hysteresis. Use Equation 2 to set the external hysteresis for the input voltage. Use Equation 3 to set the input start voltage.

**Figure 27. Adjustable Undervoltage Lockout (UVLO)**

$$R1 = \frac{V_{\text{START}} - V_{\text{STOP}}}{I_{\text{HYS}}} \quad (2)$$

## Feature Description (continued)

$$R2 = \frac{V_{ENA}}{\frac{V_{START} - V_{ENA}}{R1} + I_1} \quad (3)$$

Another technique to add input voltage hysteresis is shown in [Figure 28](#). This method may be used, if the resistance values are high from the previous method and a wider voltage hysteresis is needed. The resistor R3 sources additional hysteresis current into the EN pin.

**Figure 28. Adding Additional Hysteresis**

$$R1 = \frac{V_{START} - V_{STOP}}{I_{HYS} + \frac{V_{OUT}}{R3}} \quad (4)$$

$$R2 = \frac{V_{ENA}}{\frac{V_{START} - V_{ENA}}{R1} + I_1 - \frac{V_{ENA}}{R3}} \quad (5)$$

### 7.3.8 Slow Start/Tracking Pin (SS/TR)

The TPS54040-Q1 effectively uses the lower voltage of the internal voltage reference or the SS/TR pin voltage as the reference voltage of the power-supply and regulates the output accordingly. A capacitor on the SS/TR pin to ground implements a slow start time. The TPS54040-Q1 has an internal pull-up current source of 2 μA that charges the external slow start capacitor. The calculations for the slow start time (10% to 90%) are shown in [Equation 6](#). The voltage reference ( $V_{REF}$ ) is 0.8 V and the slow start current ( $I_{SS}$ ) is 2 μA. The slow start capacitor should remain lower than 0.47 μF and greater than 0.47 nF.

$$C_{SS}(nF) = \frac{T_{SS}(ms) \times I_{SS}(\mu A)}{V_{ref}(V) \times 0.8} \quad (6)$$

At power up, the TPS54040-Q1 will not start switching until the slow start pin is discharged to less than 40 mV to ensure a proper power up, see [Figure 29](#).

Also, during normal operation, the TPS54040-Q1 will stop switching and the SS/TR must be discharged to 40 mV, when the  $V_{IN}$  UVLO is exceeded, EN pin pulled below 1.25 V, or a thermal shutdown event occurs.

The VSENSE voltage will follow the SS/TR pin voltage with a 45-mV offset up to 85% of the internal voltage reference. When the SS/TR voltage is greater than 85% on the internal reference voltage the offset increases as the effective system reference transitions from the SS/TR voltage to the internal voltage reference (see [Figure 23](#)). The SS/TR voltage will ramp linearly until clamped at 1.7 V.

## Feature Description (continued)

**Figure 29. Operation of SS/TR Pin When Starting**

### 7.3.9 Overload Recovery Circuit

The TPS54040-Q1 has an overload recovery (OLR) circuit. The OLR circuit will slow start the output from the overload voltage to the nominal regulation voltage once the fault condition is removed. The OLR circuit will discharge the SS/TR pin to a voltage slightly greater than the VSENSE pin voltage using an internal pull down of 100  $\mu$ A when the error amplifier is changed to a high voltage from a fault condition. When the fault condition is removed, the output will slow start from the fault voltage to nominal output voltage.

### 7.3.10 Constant Switching Frequency and Timing Resistor (RT/CLK Pin)

The switching frequency of the TPS54040-Q1 is adjustable over a wide range from approximately 100 kHz to 2500 kHz by placing a resistor on the RT/CLK pin. The RT/CLK pin voltage is typically 0.5 V and must have a resistor to ground to set the switching frequency. To determine the timing resistance for a given switching frequency, use [Equation 7](#) or the curves in [Figure 30](#) or [Figure 31](#). To reduce the solution size one would typically set the switching frequency as high as possible, but tradeoffs of the supply efficiency, maximum input voltage and minimum controllable on time should be considered.

The minimum controllable on time is typically 130 ns and limits the maximum operating input voltage.

The maximum switching frequency is also limited by the frequency shift circuit. More discussion on the details of the maximum switching frequency is located below.

$$RT \text{ (k}\Omega\text{)} = \frac{206033}{f_{sw} \text{ (kHz)}^{1.0888}} \quad (7)$$

## Feature Description (continued)

### 7.3.11 Overcurrent Protection and Frequency Shift

The TPS54040-Q1 implements current mode control which uses the COMP pin voltage to turn off the high-side MOSFET on a cycle by cycle basis. Each cycle the switch current and COMP pin voltage are compared, when the peak switch current intersects the COMP voltage, the high-side switch is turned off. During overcurrent conditions that pull the output voltage low, the error amplifier will respond by driving the COMP pin high, increasing the switch current. The error amplifier output is clamped internally, which functions as a switch current limit.

To increase the maximum operating switching frequency at high input voltages the TPS54040-Q1 implements a frequency shift. The switching frequency is divided by 8, 4, 2, and 1 as the voltage ramps from 0 to 0.8 V on VSENSE pin.

The device implements a digital frequency shift to enable synchronizing to an external clock during normal startup and fault conditions. Since the device can only divide the switching frequency by 8, there is a maximum input voltage limit in which the device operates and still have frequency shift protection.

During short-circuit events (particularly with high input voltage applications), the control loop has a finite minimum controllable on time and the output has a low voltage. During the switch on time, the inductor current ramps to the peak current limit because of the high input voltage and minimum on time. During the switch off time, the inductor would normally not have enough off time and output voltage for the inductor to ramp down by the ramp up amount. The frequency shift effectively increases the off time allowing the current to ramp down.

### 7.3.12 Selecting the Switching Frequency

The switching frequency that is selected should be the lower value of the two equations, [Equation 8](#) and [Equation 9](#). [Equation 8](#) is the maximum switching frequency limitation set by the minimum controllable on time. Setting the switching frequency above this value will cause the regulator to skip switching pulses.

[Equation 9](#) is the maximum switching frequency limit set by the frequency shift protection. To have adequate output short circuit protection at high input voltages, the switching frequency should be set to be less than the  $f_{SW(maxshift)}$  frequency. In [Equation 9](#), to calculate the maximum switching frequency one must take into account that the output voltage decreases from the nominal voltage to 0 V, the  $f_{DIV}$  integer increases from 1 to 8 corresponding to the frequency shift.

## Feature Description (continued)

In [Figure 32](#), the solid line illustrates a typical safe operating area regarding frequency shift and assumes the output voltage is zero volts, and the resistance of the inductor is 0.130 Ω, FET on resistance of 0.2 Ω and the diode voltage drop is 0.5 V. The dashed line is the maximum switching frequency to avoid pulse skipping. Enter these equations in a spreadsheet or other software or use the SwitcherPro design software to determine the switching frequency.

$$f_{SW(max\ skip)} = \left( \frac{1}{t_{ON}} \right) \times \left( \frac{(I_L \times R_{dc} + V_{OUT} + V_d)}{(V_{IN} - I_L \times R_{hs} + V_d)} \right) \quad (8)$$

$$f_{SW(hift)} = \frac{f_{div}}{t_{ON}} \times \left( \frac{(I_L \times R_{dc} + V_{OUTSC} + V_d)}{(V_{IN} - I_L \times R_{hs} + V_d)} \right) \quad (9)$$

$I_L$	inductor current
$R_{dc}$	inductor resistance
$V_{IN}$	maximum input voltage
$V_{OUT}$	output voltage
$V_{OUTSC}$	output voltage during short
$V_d$	diode voltage drop
$R_{DS(ON)}$	switch on resistance
$t_{ON}$	controllable on time
$f_{DIV}$	frequency divide equals (1, 2, 4, or 8)

**Figure 32. Maximum Switching Frequency vs. Input Voltage**

### 7.3.13 Power-good (PWRGD Pin)

The PWRGD pin is an open drain output. Once the VSENSE pin is between 94% and 107% of the internal voltage reference the PWRGD pin is deasserted and the pin floats. It is recommended to use a pullup resistor between the values of 1 kΩ and 100 kΩ to a voltage source that is 5.5 V or less. The PWRGD is in a defined state once the  $V_{IN}$  input voltage is greater than 1.5 V but with reduced current sinking capability. The PWRGD will achieve full current sinking capability as  $V_{IN}$  input voltage approaches 3 V.

The PWRGD pin is pulled low when the VSENSE is lower than 92% or greater than 109% of the nominal internal reference voltage. Also, the PWRGD is pulled low, if the UVLO or thermal shutdown are asserted or the EN pin pulled low.

## Feature Description (continued)

### 7.3.14 Overvoltage Transient Protection

The TPS54040-Q1 incorporates an overvoltage transient protection (OVTP) circuit to minimize voltage overshoot when recovering from output fault conditions or strong unload transients on power supply designs with low value output capacitance. For example, when the power supply output is overloaded the error amplifier compares the actual output voltage to the internal reference voltage. If the VSENSE pin voltage is lower than the internal reference voltage for a considerable time, the output of the error amplifier will respond by clamping the error amplifier output to a high voltage. Thus, requesting the maximum output current. Once the condition is removed, the regulator output rises and the error amplifier output transitions to the steady state duty cycle. In some applications, the power supply output voltage can respond faster than the error amplifier output can respond, this actuality leads to the possibility of an output overshoot. The OVTP feature minimizes the output overshoot, when using a low value output capacitor, by implementing a circuit to compare the VSENSE pin voltage to OVTP threshold which is 109% of the internal voltage reference. If the VSENSE pin voltage is greater than the OVTP threshold, the high-side MOSFET is disabled preventing current from flowing to the output and minimizing output overshoot. When the VSENSE voltage drops lower than the OVTP threshold, the high-side MOSFET is allowed to turn on at the next clock cycle.

### 7.3.15 Thermal Shutdown

The device implements an internal thermal shutdown to protect itself if the junction temperature exceeds 182°C. The thermal shutdown forces the device to stop switching when the junction temperature exceeds the thermal trip threshold. Once the die temperature decreases below 182°C, the device reinitiates the power up sequence by discharging the SS/TR pin.

### 7.3.16 Small Signal Model for Loop Response

Figure 33 shows an equivalent model for the TPS54040-Q1 control loop which can be modeled in a circuit simulation program to check frequency response and dynamic load response. The error amplifier is a transconductance amplifier with a  $g_{m_{EA}}$  of 97  $\mu\text{A/V}$ . The error amplifier can be modeled using an ideal voltage controlled current source. The resistor  $R_o$  and capacitor  $C_o$  model the open loop gain and frequency response of the amplifier. The 1-mV ac voltage source between the nodes a and b effectively breaks the control loop for the frequency response measurements. Plotting c/a shows the small signal response of the frequency compensation. Plotting a/b shows the small signal response of the overall loop. The dynamic loop response can be checked by replacing  $R_L$  with a current source with the appropriate load step amplitude and step rate in a time domain analysis. This equivalent model is only valid for continuous conduction mode designs.

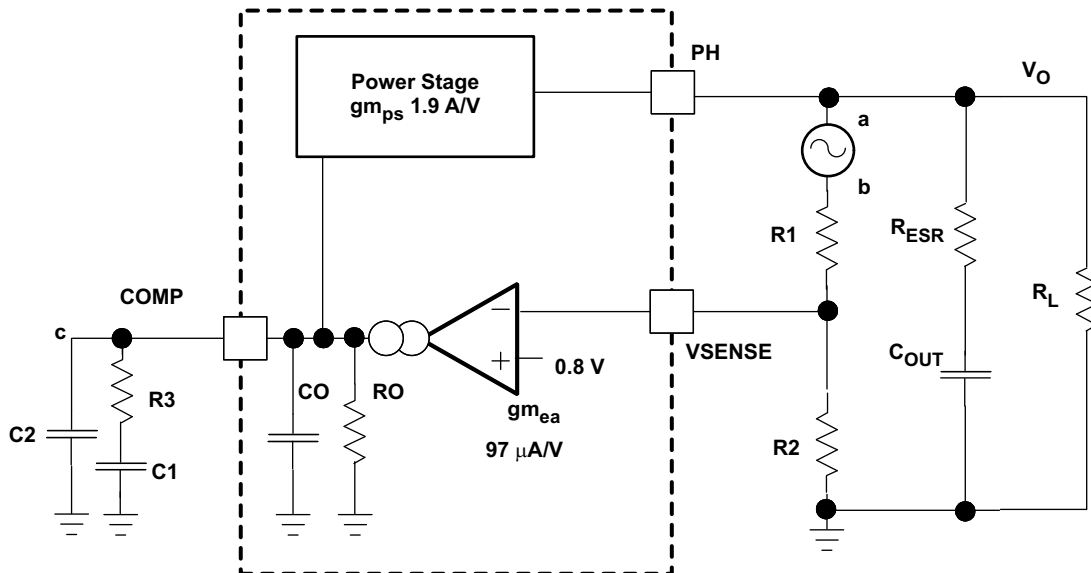

Figure 33. Small Signal Model for Loop Response

## Feature Description (continued)

### 7.3.17 Simple Small Signal Model for Peak Current Mode Control

Figure 34 describes a simple small signal model that can be used to understand how to design the frequency compensation. The TPS54040-Q1 power stage can be approximated to a voltage-controlled current source (duty cycle modulator) supplying current to the output capacitor and load resistor. The control to output transfer function is shown in Equation 10 and consists of a dc gain, one dominant pole, and one ESR zero. The quotient of the change in switch current and the change in COMP pin voltage (node c in Figure 33) is the power stage transconductance. The  $g_{m_{ps}}$  for the TPS54040-Q1 is 1.9 A/V. The low-frequency gain of the power stage frequency response is the product of the transconductance and the load resistance as shown in Equation 11.

As the load current increases and decreases, the low-frequency gain decreases and increases, respectively. This variation with the load may seem problematic at first glance, but fortunately the dominant pole moves with the load current (see Equation 12). The combined effect is highlighted by the dashed line in the right half of Figure 34. As the load current decreases, the gain increases and the pole frequency lowers, keeping the 0-dB crossover frequency the same for the varying load conditions which makes it easier to design the frequency compensation. The type of output capacitor chosen determines whether the ESR zero has a profound effect on the frequency compensation design. Using high ESR aluminum electrolytic capacitors may reduce the number frequency compensation components needed to stabilize the overall loop because the phase margin increases from the ESR zero at the lower frequencies (see Equation 13).

**Figure 34. Simple Small Signal Model and Frequency Response for Peak Current Mode Control**

$$\frac{V_{OUT}}{V_C} = A_{dc} \times \frac{\left(1 + \frac{s}{2\pi \times f_Z}\right)}{\left(1 + \frac{s}{2\pi \times f_P}\right)} \quad (10)$$

$$A_{dc} = g_{m_{ps}} \times R_L \quad (11)$$

$$f_P = \frac{1}{C_{OUT} \times R_L \times 2\pi} \quad (12)$$

$$f_Z = \frac{1}{C_{OUT} \times R_{ESR} \times 2\pi} \quad (13)$$

## Feature Description (continued)

### 7.3.18 Small Signal Model for Frequency Compensation

The TPS54040-Q1 uses a transconductance amplifier for the error amplifier and readily supports three of the commonly-used frequency compensation circuits. Compensation circuits Type 2A, Type 2B, and Type 1 are shown in Figure 35. Type 2 circuits most likely implemented in high bandwidth power-supply designs using low ESR output capacitors. The Type 1 circuit is used with power-supply designs with high-ESR aluminum electrolytic or tantalum capacitors. Equation 14 and Equation 15 show how to relate the frequency response of the amplifier to the small signal model in Figure 35. The open-loop gain and bandwidth are modeled using the  $R_O$  and  $C_O$  shown in Figure 35. See the application section for a design example using a Type 2A network with a low ESR output capacitor.

Equation 14 through Equation 23 are provided as a reference for those who prefer to compensate using the preferred methods. Those who prefer to use prescribed method use the method outlined in the application section or use switched information.

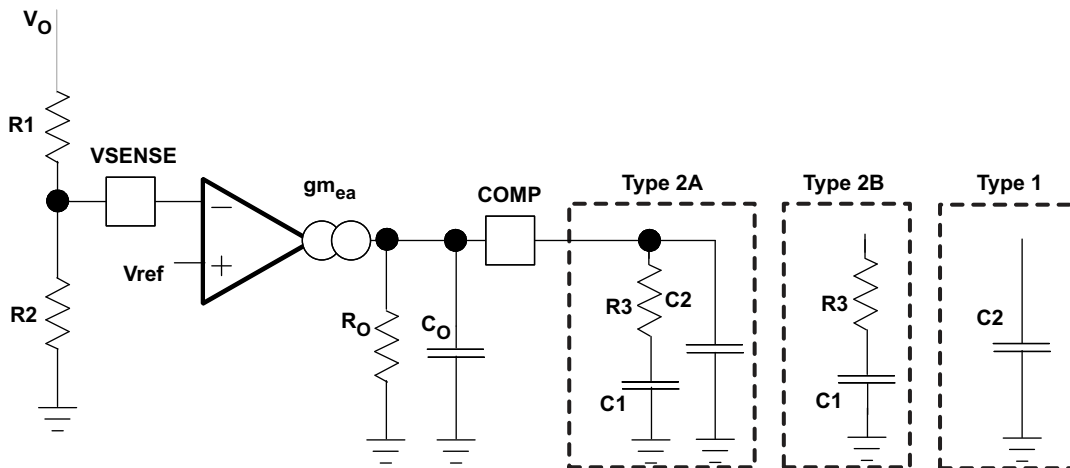

Figure 35. Types of Frequency Compensation

Figure 36. Frequency Response of the Type 2A and Type 2B Frequency Compensation

$$R_O = \frac{A_{ol}(V/V)}{g_{m_{ea}}} \quad (14)$$

$$C_O = \frac{g_{m_{ea}}}{2\pi \times BW \text{ (Hz)}} \quad (15)$$

## Feature Description (continued)

$$EA = A0 \times \frac{\left(1 + \frac{s}{2\pi \times f_{Z1}}\right)}{\left(1 + \frac{s}{2\pi \times f_{P1}}\right) \times \left(1 + \frac{s}{2\pi \times f_{P2}}\right)} \quad (16)$$

$$A0 = g_{m_{ea}} \times R_o \times \frac{R2}{R1 + R2} \quad (17)$$

$$A1 = g_{m_{ea}} \times R_o || R3 \times \frac{R2}{R1 + R2} \quad (18)$$

$$P1 = \frac{1}{2\pi \times R_o \times C1} \quad (19)$$

$$Z1 = \frac{1}{2\pi \times R3 \times C1} \quad (20)$$

$$P2 = \frac{1}{2\pi \times R3 || R_o \times (C2 + C_o)} \text{ type 2a} \quad (21)$$

$$P2 = \frac{1}{2\pi \times R3 || R_o \times C_o} \text{ type 2b} \quad (22)$$

$$P2 = \frac{1}{2\pi \times R_o \times (C2 + C_o)} \text{ type 1} \quad (23)$$

## 7.4 Device Functional Modes

### 7.4.1 Pulse-Skip Eco-Mode

The TPS54040-Q1 operates in a pulse-skip Eco-Mode at light load currents to improve efficiency by reducing switching and gate drive losses. The TPS54040-Q1 is designed so that if the output voltage is within regulation and the peak switch current at the end of any switching cycle is below the pulse skipping current threshold, the device enters Eco-Mode. This current threshold is the current level corresponding to a nominal COMP voltage or 500 mV.

When in Eco-Mode, the COMP pin voltage is clamped at 500 mV and the high-side MOSFET is inhibited. Further decreases in load current or in output voltage can not drive the COMP pin below this clamp voltage level.

Since the device is not switching, the output voltage begins to decay. As the voltage control loop compensates for the falling output voltage, the COMP pin voltage begins to rise. At this time, the high-side MOSFET is enabled and a switching pulse initiates on the next switching cycle. The peak current is set by the COMP pin voltage. The output voltage re-charges the regulated value (see [Figure 37](#)), then the peak switch current starts to decrease, and eventually falls below the Eco-Mode threshold at which time the device again enters Eco-Mode.

## Device Functional Modes (continued)

For Eco-Mode operation, the TPS54040-Q1 senses peak current, not average or load current, so the load current where the device enters Eco-Mode is dependent on the output inductor value. For example, the circuit in [Figure 50](#) enters Eco-Mode at about 20 mA of output current. When the load current is low and the output voltage is within regulation, the device enters a sleep mode and draws only 116- $\mu$ A input quiescent current. The internal PLL remains operating when in sleep mode. When operating at light load currents in the pulse skip mode, the switching transitions occur synchronously with the external clock signal.

Figure 37. Pulse Skip Mode Operation

### 7.4.2 External Clock Synchronization Using RT/CLK Pin

The RT/CLK pin can be used to synchronize the regulator to an external system clock. To implement the synchronization feature connect a square wave to the RT/CLK pin through the circuit network shown in [Figure 38](#). The square wave amplitude must transition lower than 0.5 V and higher than 2.2 V on the RT/CLK pin and have an on time greater than 40 ns and an off time greater than 40 ns. The synchronization frequency range is 300 kHz to 2200 kHz. The rising edge of the PH will be synchronized to the falling edge of RT/CLK pin signal. The external synchronization circuit should be designed in such a way that the device will have the default frequency set resistor connected from the RT/CLK pin to ground should the synchronization signal turn off. It is recommended to use a frequency set resistor connected as shown in [Figure 38](#) through a 50- $\Omega$  resistor to ground. The resistor should set the switching frequency close to the external CLK frequency. It is recommended to ac couple the synchronization signal through a 10-pF ceramic capacitor to RT/CLK pin and a 4-k $\Omega$  series resistor. The series resistor reduces PH jitter in heavy load applications when synchronizing to an external clock and in applications which transition from synchronizing to RT mode. The first time the CLK is pulled above the CLK threshold the device switches from the RT resistor frequency to PLL mode. The internal 0.5-V voltage source is removed and the CLK pin becomes high impedance as the PLL starts to lock onto the external signal. Since there is a PLL on the regulator the switching frequency can be higher or lower than the frequency set with the external resistor. The device transitions from the resistor mode to the PLL mode and then will increase or decrease the switching frequency until the PLL locks onto the CLK frequency within 100 microseconds.

## Device Functional Modes (continued)

When the device transitions from the PLL to resistor mode the switching frequency will slow down from the CLK frequency to 150 kHz, then reapply the 0.5-V voltage and the resistor will then set the switching frequency. The switching frequency is divided by 8, 4, 2, and 1 as the voltage ramps from 0 to 0.8 volts on VSENSE pin. The device implements a digital frequency shift to enable synchronizing to an external clock during normal startup and fault conditions. Figure 39, Figure 40 and Figure 41 show the device synchronized to an external system clock in continuous conduction mode (CCM) discontinuous conduction (DCM) and pulse skip mode (PSM).

**Figure 38. Synchronizing to a System Clock**

Device Functional Modes (continued)

Figure 41. Plot of Synchronizing in PSM

## 8 Application and Implementation

### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 8.1 Application Information

The TPS54040-Q1 device is a wide input voltage (3.5 V to 42 V), step-down, DC-DC converter with an adjustable output voltage and an output current of up to 0.5 A. Switching frequency is adjustable between 100-kHz to 2.5-MHz and hence efficiency and external component size can be optimized for each application.

#### 8.1.1 Sequencing

Many of the common power supply sequencing methods can be implemented using the SS/TR, EN and PWRGD pins. The sequential method can be implemented using an open drain output of a power-on reset pin of another device. The sequential method is illustrated in Figure 42 using two TPS54040-Q1 devices. The power-good is coupled to the EN pin on the TPS54040-Q1 which will enable the second power supply once the primary supply reaches regulation. If needed, a 1-nF ceramic capacitor on the EN pin of the second power supply will provide a 1-ms start-up delay. Figure 43 shows the results of Figure 42.

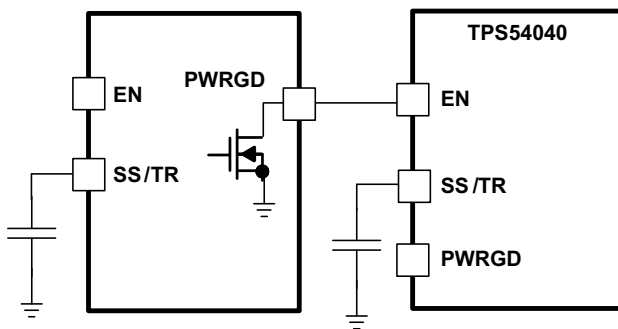

Figure 42. Schematic for Sequential Start-Up Sequence

Figure 43. Sequential Start-Up Using EN and PWRGD

Application Information (continued)

Figure 44. Schematic for Ratiometric Start-up Using Coupled SS/TR Pins

Figure 45. Ratiometric Start-up Using Coupled SS/TR Pins

Figure 44 shows a method for ratiometric start-up sequence by connecting the SS/TR pins together. The regulator outputs will ramp up and reach regulation at the same time. When calculating the slow start time the pullup current source must be doubled in Equation 6. Figure 45 shows the results of Figure 44.

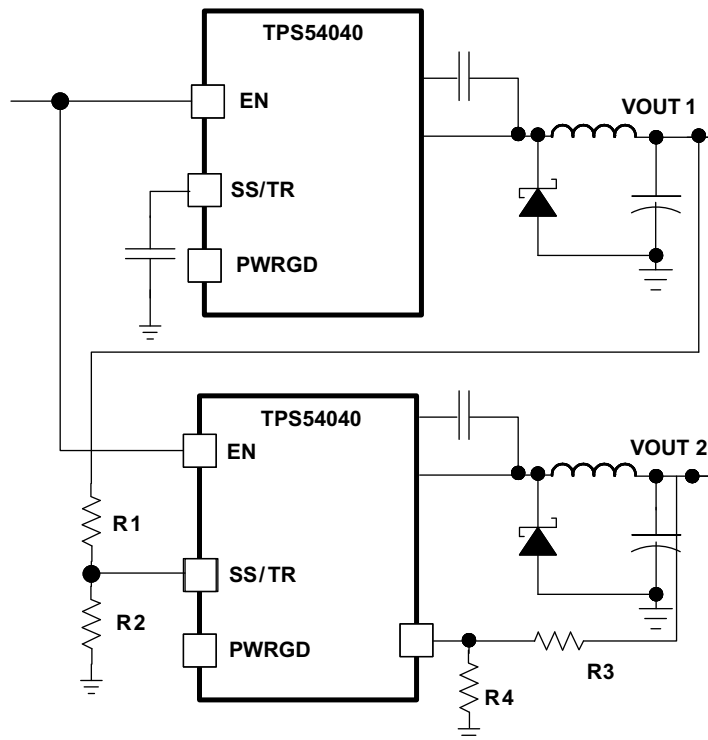

Figure 46. Schematic for Ratiometric and Simultaneous Start-up Sequence

## Application Information (continued)

Ratiometric and simultaneous power-supply sequencing can be implemented by connecting the resistor network of R1 and R2 shown in [Figure 46](#) to the output of the power supply that needs to be tracked or another voltage reference source. Using [Equation 24](#) and [Equation 25](#), the tracking resistors can be calculated to initiate the  $V_{OUT2}$  slightly before, after or at the same time as  $V_{OUT1}$ . [Equation 26](#) is the voltage difference between  $V_{OUT1}$  and  $V_{OUT2}$  at the 95% of nominal output regulation.

The  $\Delta V$  variable is zero volts for simultaneous sequencing. To minimize the effect of the inherent SS/TR to VSENSE offset ( $V_{SSOFFSET}$ ) in the slow start circuit and the offset created by the pullup current source ( $I_{SS}$ ) and tracking resistors, the  $V_{SSOFFSET}$  and  $I_{SS}$  are included as variables in the equations.

To design a ratiometric start-up in which the  $V_{OUT2}$  voltage is slightly greater than the  $V_{OUT1}$  voltage when  $V_{OUT2}$  reaches regulation, use a negative number in [Equation 24](#) through [Equation 26](#) for  $\Delta V$ . [Equation 26](#) will result in a positive number for applications which the  $V_{OUT2}$  is slightly lower than  $V_{OUT1}$  when  $V_{OUT2}$  regulation is achieved.

Since the SS/TR pin must be pulled below 40 mV before starting after an EN, UVLO or thermal shutdown fault, careful selection of the tracking resistors is needed to ensure the device will restart after a fault. Make sure the calculated R1 value from [Equation 24](#) is greater than the value calculated in [Equation 27](#) to ensure the device can recover from a fault.

As the SS/TR voltage becomes more than 85% of the nominal reference voltage the  $V_{SSOFFSET}$  becomes larger as the slow start circuits gradually handoff the regulation reference to the internal voltage reference. The SS/TR pin voltage needs to be greater than 1.3 V for a complete handoff to the internal voltage reference as shown in [Figure 23](#).

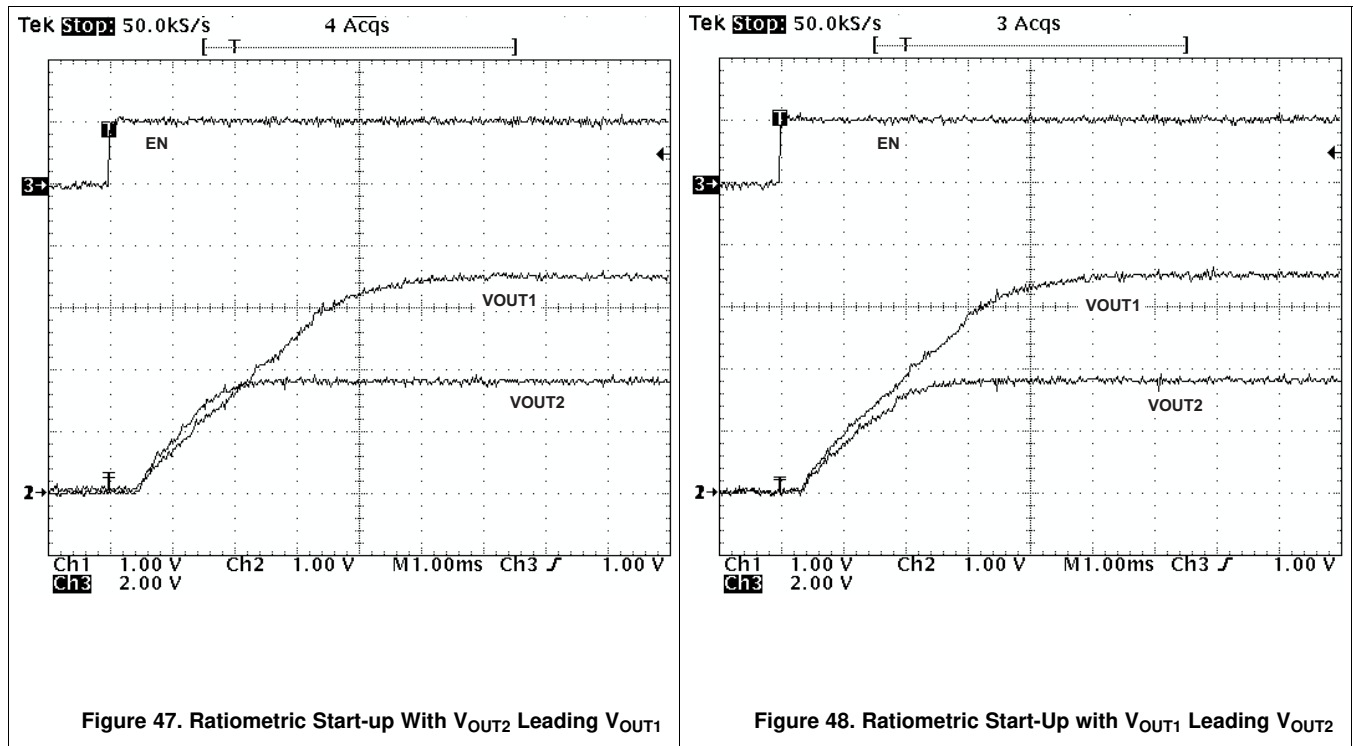

$$R1 = \frac{V_{out2} + \Delta V}{V_{REF}} \times \frac{V_{ssoffset}}{I_{ss}} \quad (24)$$

$$R2 = \frac{V_{REF} \times R1}{V_{out2} + \Delta V - V_{REF}} \quad (25)$$

$$\Delta V = V_{out1} - V_{out2} \quad (26)$$

$$R1 > 2800 \times V_{out1} - 180 \times \Delta V \quad (27)$$

**Application Information (continued)**

## 8.2 Typical Application

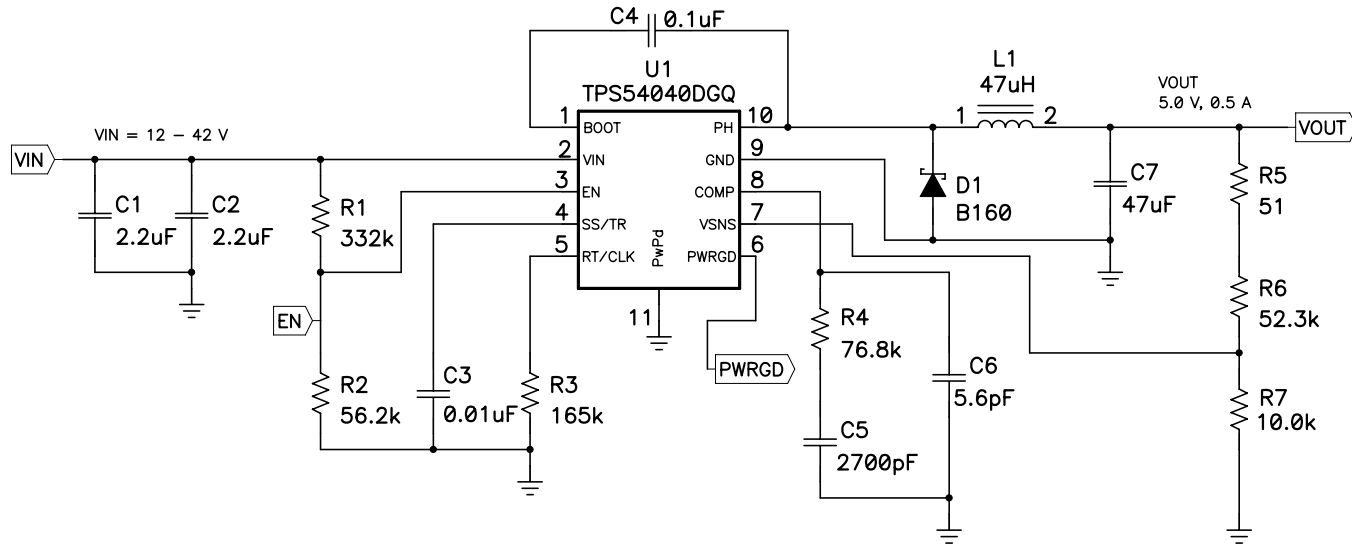

Figure 50. High Frequency, 3.3-V Output Power Supply Design With Adjusted UVLO

### 8.2.1 Design Requirements

The input voltage for this device must be from 3.5 V to 42 V. The output voltage must be set using an external voltage divider. Schottky diode must be used at PH pin to GND as there is no integrated recirculation path in the device. Switching frequency has to be set as per the requirement by calculating pull down resistor value at RT/CLK pin. Compensation network component have to be calculated as explained in [Detailed Design Procedure](#). Low-ESR ceramic capacitors should be used at the input and output for better filtering and ripple performance and effective input capacitance has to be at least 3 uF.

The [Detailed Design Procedure](#) section provides the necessary equations and guidelines for selecting external components for this regulator.

### 8.2.2 Detailed Design Procedure

This example details the design of a high frequency switching regulator using ceramic output capacitors. A few parameters must be known in order to start the design process. These parameters are typically determined at the system level. [Table 1](#) shows the known parameters for this example.

Table 1. Known Parameters for This Regulator Design Example

PARAMETER	VALUE
Output Voltage	5 V
Transient Response 0 to 1.5A load step	$\Delta V_{OUT} = 4\%$
Maximum Output Current	0.5 A
Input Voltage	34 V nom. 12 V to 42 V
Output Voltage Ripple	1% of $V_{OUT}$
Start Input Voltage (rising $V_{IN}$ )	8.9 V
Stop Input Voltage (falling $V_{IN}$ )	7.9 V

### 8.2.2.1 Selecting the Switching Frequency

The first step is to decide on a switching frequency for the regulator. Typically, the user will want to choose the highest switching frequency possible since this will produce the smallest solution size. The high switching frequency allows for lower valued inductors and smaller output capacitors compared to a power supply that switches at a lower frequency. The switching frequency that can be selected is limited by the minimum on-time of the internal power switch, the input voltage and the output voltage and the frequency shift limitation.

[Equation 8](#) and [Equation 9](#) must be used to find the maximum switching frequency for the regulator, choose the lower value of the two equations. Switching frequencies higher than these values will result in pulse skipping or the lack of overcurrent protection during a short circuit.

The typical minimum on time,  $t_{onmin}$ , is 130 ns for the TPS54040-Q1. For this example, the output voltage is 5 V and the maximum input voltage is 42 V, which allows for a maximum switch frequency up to 1012 kHz when including the inductor resistance, on resistance and diode voltage in [Equation 8](#). To ensure overcurrent runaway is not a concern during short circuits in your design use [Equation 9](#) or the solid curve in [Figure 32](#) to determine the maximum switching frequency. With a maximum input voltage of 42 V, assuming a diode voltage of 0.5 V, inductor resistance of 130 mΩ, switch resistance of 400 mΩ, a current limit value of 0.94 A and a short circuit output voltage of 0.1 V. The maximum switching frequency is approximately 1055 kHz.

Choosing the lower of the two values and adding some margin a switching frequency of 700 kHz is used. To determine the timing resistance for a given switching frequency, use [Equation 7](#) or the curve in [Figure 30](#).

The switching frequency is set by resistor R3 shown in [Figure 50](#).

### 8.2.2.2 Output Inductor Selection ( $L_O$ )

To calculate the minimum value of the output inductor, use [Equation 28](#).

$K_{IND}$  is a coefficient that represents the amount of inductor ripple current relative to the maximum output current.

The inductor ripple current will be filtered by the output capacitor. Therefore, choosing high inductor ripple currents will impact the selection of the output capacitor since the output capacitor must have a ripple current rating equal to or greater than the inductor ripple current. In general, the inductor ripple value is at the discretion of the designer; however, the following guidelines may be used.

For designs using low ESR output capacitors such as ceramics, a value as high as  $K_{IND} = 0.3$  may be used. When using higher ESR output capacitors,  $K_{IND} = 0.2$  yields better results. Since the inductor ripple current is part of the PWM control system, the inductor ripple current should always be greater than 30 mA for dependable operation. In a wide input voltage regulator, it is best to choose an inductor ripple current on the larger side. This allows the inductor to still have a measurable ripple current with the input voltage at its minimum.

For this design example, use  $K_{IND} = 0.3$  and the minimum inductor value is calculated to be 42 μH. For this design, a nearest standard value was chosen: 47 μH. For the output filter inductor, it is important that the RMS current and saturation current ratings not be exceeded. The RMS and peak inductor current can be found from [Equation 30](#) and [Equation 31](#).

For this design, the RMS inductor current is 0.501 A and the peak inductor current is 0.567 A. The chosen inductor is a MSS1048-473ML. It has a saturation current rating of 1.44 A and an RMS current rating of 1.83 A.

As the equation set demonstrates, lower ripple currents will reduce the output voltage ripple of the regulator but will require a larger value of inductance. Selecting higher ripple currents will increase the output voltage ripple of the regulator but allow for a lower inductance value.

The current flowing through the inductor is the inductor ripple current plus the output current. During power up, faults or transient load conditions, the inductor current can increase above the calculated peak inductor current level calculated above. In transient conditions, the inductor current can increase up to the switch current limit of the device. For this reason, the most conservative approach is to specify an inductor with a saturation current rating equal to or greater than the switch current limit rather than the peak inductor current.

$$L_{O \min} = \frac{V_{inmax} - V_{out}}{I_o \times K_{IND}} \times \frac{V_{out}}{V_{inmax} \times f_{sw}} \quad (28)$$

$$I_{\text{RIPPLE}} = \frac{V_{\text{OUT}} \times (V_{\text{inmax}} - V_{\text{OUT}})}{V_{\text{inmax}} \times L_{\text{O}} \times f_{\text{SW}}} \quad (29)$$

$$L_{(\text{rms})} = \sqrt{(I_{\text{O}})^2 + \frac{1}{12} \times \left( \frac{V_{\text{OUT}} \times (V_{\text{inmax}} - V_{\text{OUT}})}{V_{\text{inmax}} \times L_{\text{O}} \times f_{\text{SW}}} \right)^2} \quad (30)$$

$$I_{\text{Lpeak}} = I_{\text{out}} + \frac{I_{\text{ripple}}}{2} \quad (31)$$

### 8.2.2.3 Output Capacitor

There are three primary considerations for selecting the value of the output capacitor. The output capacitor will determine the modulator pole, the output voltage ripple, and how the regulators responds to a large change in load current. The output capacitance needs to be selected based on the more stringent of these three criteria.

The desired response to a large change in the load current is the first criteria. The output capacitor needs to supply the load with current when the regulator can not. This situation would occur if there are desired hold-up times for the regulator where the output capacitor must hold the output voltage above a certain level for a specified amount of time after the input power is removed. The regulator also will temporarily not be able to supply sufficient output current if there is a large, fast increase in the current needs of the load such as transitioning from no load to a full load. The regulator usually needs two or more clock cycles for the control loop to see the change in load current and output voltage and adjust the duty cycle to react to the change. The output capacitor must be sized to supply the extra current to the load until the control loop responds to the load change. The output capacitance must be large enough to supply the difference in current for 2 clock cycles while only allowing a tolerable amount of droop in the output voltage. Equation 32 shows the minimum output capacitance necessary to accomplish this.

Where  $\Delta I_{\text{OUT}}$  is the change in output current,  $f_{\text{sw}}$  is the regulators switching frequency and  $\Delta V_{\text{OUT}}$  is the allowable change in the output voltage. For this example, the transient load response is specified as a 4% change in  $V_{\text{OUT}}$  for a load step from 0 A (no load) to 0.5 A (full load). For this example,  $\Delta I_{\text{OUT}} = 0.5 - 0 = 0.5$  A and  $\Delta V_{\text{OUT}} = 0.04 \times 5 = 0.2$  V. Using these numbers gives a minimum capacitance of 7.14  $\mu\text{F}$ . This value does not take the ESR of the output capacitor into account in the output voltage change. For ceramic capacitors, the ESR is usually small enough to ignore in this calculation. Aluminum electrolytic and tantalum capacitors have higher ESR that should be taken into account.

The catch diode of the regulator can not sink current so any stored energy in the inductor will produce an output voltage overshoot when the load current rapidly decreases, see Figure 51. The output capacitor must also be sized to absorb energy stored in the inductor when transitioning from a high load current to a lower load current. The excess energy that gets stored in the output capacitor will increase the voltage on the capacitor. The capacitor must be sized to maintain the desired output voltage during these transient periods. Equation 33 is used to calculate the minimum capacitance to keep the output voltage overshoot to a desired value. Where  $L$  is the value of the inductor,  $I_{\text{OH}}$  is the output current under heavy load,  $I_{\text{OL}}$  is the output under light load,  $V_f$  is the final peak output voltage, and  $V_i$  is the initial capacitor voltage. For this example, the worst case load step will be from 0.5 A to 0 A. The output voltage will increase during this load transition and the stated maximum in our specification is 4% of the output voltage. This will make  $V_f = 1.04 \times 5 = 5.2$  V.  $V_i$  is the initial capacitor voltage which is the nominal output voltage of 5 V. Using these numbers in Equation 33 yields a minimum capacitance of 5.7  $\mu\text{F}$ .

Equation 34 calculates the minimum output capacitance needed to meet the output voltage ripple specification. Where  $f_{\text{sw}}$  is the switching frequency,  $V_{\text{ripple}}$  is the maximum allowable output voltage ripple, and  $I_{\text{ripple}}$  is the inductor ripple current. Equation 34 yields 0.49  $\mu\text{F}$ .

Equation 35 calculates the maximum ESR an output capacitor can have to meet the output voltage ripple specification. Equation 35 indicates the ESR should be less than 248 m $\Omega$ .

The most stringent criteria for the output capacitor is 7.14  $\mu\text{F}$  of capacitance to keep the output voltage in regulation during an load transient.

Additional capacitance de-ratings for aging, temperature and dc bias should be factored in which will increase this minimum value. For this example, a 47- $\mu$ F 10-V X5R ceramic capacitor with 5 m $\Omega$  of ESR will be used.

Capacitors generally have limits to the amount of ripple current they can handle without failing or producing excess heat. An output capacitor that can support the inductor ripple current must be specified. Some capacitor data sheets specify the root mean square (RMS) value of the maximum ripple current. Equation 36 can be used to calculate the RMS ripple current the output capacitor needs to support. For this application, Equation 36 yields 39 mA.

$$C_{out} > \frac{2 \times \Delta I_{out}}{f_{sw} \times \Delta V_{out}} \quad (32)$$

$$C_{OUT} > L_O \times \frac{\left( (I_{OH})^2 - (I_{OL})^2 \right)}{\left( (V_f)^2 - (V_i)^2 \right)} \quad (33)$$

$$C_{out} > \frac{1}{8 \times f_{sw}} \times \frac{1}{\left( \frac{V_{ORIPPLE}}{I_{RIPPLE}} \right)} \quad (34)$$

$$R_{ESR} < \frac{V_{ORIPPLE}}{I_{RIPPLE}} \quad (35)$$

$$I_{corms} = \frac{V_{out} \times (V_{in\ max} - V_{out})}{\sqrt{12} \times V_{in\ max} \times L_O \times f_{sw}} \quad (36)$$

#### 8.2.2.4 Catch Diode

The TPS54040-Q1 requires an external catch diode between the PH pin and GND. The selected diode must have a reverse voltage rating equal to or greater than  $V_{IN(max)}$ . The peak current rating of the diode must be greater than the maximum inductor current. The diode should also have a low forward voltage. Schottky diodes are typically a good choice for the catch diode due to their low forward voltage. The lower the forward voltage of the diode, the higher the efficiency of the regulator.

Typically, the higher the voltage and current ratings the diode has, the higher the forward voltage will be. Since the design example has an input voltage up to 42 V, a diode with a minimum of 42-V reverse voltage will be selected.

For the example design, the B160A Schottky diode is selected for its lower forward voltage and it comes in a larger package size which has good thermal characteristics over small devices. The typical forward voltage of the B160A is 0.50 volts.

The diode must also be selected with an appropriate power rating. The diode conducts the output current during the off-time of the internal power switch. The off-time of the internal switch is a function of the maximum input voltage, the output voltage, and the switching frequency. The output current during the off-time is multiplied by the forward voltage of the diode which equals the conduction losses of the diode. At higher switch frequencies, the ac losses of the diode need to be taken into account. The ac losses of the diode are due to the charging and discharging of the junction capacitance and reverse recovery. Equation 37 is used to calculate the total power dissipation, conduction losses plus ac losses, of the diode.

The B160A has a junction capacitance of 110 pF. Using Equation 37, the selected diode will dissipate 0.290 Watts. This power dissipation, depending on mounting techniques, should produce a 5.9°C temperature rise in the diode when the input voltage is 42 V and the load current is 0.5 A.

If the power supply spends a significant amount of time at light load currents or in sleep mode consider using a diode which has a low leakage current and slightly higher forward voltage drop.

$$P_d = \frac{(V_{in\ max} - V_{out}) \times I_{out} \times V_{fd} + C_j \times f_{sw} \times (V_{in} + V_{fd})^2}{V_{in\ max} \times 2} \quad (37)$$

### 8.2.2.5 Input Capacitor

The TPS54040-Q1 requires a high quality ceramic, type X5R or X7R, input decoupling capacitor of at least 3  $\mu\text{F}$  of effective capacitance and in some applications a bulk capacitance. The effective capacitance includes any dc bias effects. The voltage rating of the input capacitor must be greater than the maximum input voltage. The capacitor must also have a ripple current rating greater than the maximum input current ripple of the TPS54040-Q1. The input ripple current can be calculated using [Equation 38](#).

The value of a ceramic capacitor varies significantly over temperature and the amount of dc bias applied to the capacitor. The capacitance variations due to temperature can be minimized by selecting a dielectric material that is stable over temperature. X5R and X7R ceramic dielectrics are usually selected for power regulator capacitors because they have a high capacitance to volume ratio and are fairly stable over temperature. The output capacitor must also be selected with the dc bias taken into account. The capacitance value of a capacitor decreases as the dc bias across a capacitor increases.

For this example design, a ceramic capacitor with at least a 60-V voltage rating is required to support the maximum input voltage. Common standard ceramic capacitor voltage ratings include 4 V, 6.3 V, 10 V, 16 V, 25 V, 50 V or 100 V so a 100-V capacitor should be selected. For this example, two 2.2- $\mu\text{F}$ , 100-V capacitors in parallel have been selected. The input capacitance value determines the input ripple voltage of the regulator. The input voltage ripple can be calculated using [Equation 39](#). Using the design example values,  $I_{OUT(max)} = 0.5\ \text{A}$ ,  $C_{IN} = 4.4\ \mu\text{F}$ ,  $f_{sw} = 500\ \text{kHz}$ , yields an input voltage ripple of 40.6 mV and an RMS input ripple current of 0.247 A.

$$I_{cirms} = I_{out} \times \sqrt{\frac{V_{out}}{V_{in\ min}} \times \frac{(V_{in\ min} - V_{out})}{V_{in\ min}}} \quad (38)$$

$$\Delta V_{in} = \frac{I_{out\ max} \times 0.25}{C_{in} \times f_{sw}} \quad (39)$$

### 8.2.2.6 Slow Start Capacitor

The slow start capacitor determines the minimum amount of time it will take for the output voltage to reach its nominal programmed value during power up. This is useful if a load requires a controlled voltage slew rate. This is also used if the output capacitance is large and would require large amounts of current to quickly charge the capacitor to the output voltage level. The large currents necessary to charge the capacitor may make the TPS54040-Q1 reach the current limit or excessive current draw from the input power supply may cause the input voltage rail to sag. Limiting the output voltage slew rate solves both of these problems.

The slow start time must be long enough to allow the regulator to charge the output capacitor up to the output voltage without drawing excessive current. [Equation 40](#) can be used to find the minimum slow start time,  $T_{SS}$ , necessary to charge the output capacitor,  $C_{OUT}$ , from 10% to 90% of the output voltage,  $V_{OUT}$ , with an average slow start current of  $I_{SSAVG}$ . In the example, to charge the 47- $\mu\text{F}$  output capacitor up to 5 V while only allowing the average input current to be 0.125 A would require a 1.5-ms slow start time.

Once the slow start time is known, the slow start capacitor value can be calculated using [Equation 6](#). For the example circuit, the slow start time is not too critical since the output capacitor value is 47  $\mu\text{F}$  which does not require much current to charge to 5 V. The example circuit has the slow start time set to an arbitrary value of 3.2 ms which requires a 0.01- $\mu\text{F}$  capacitor.

$$T_{ss} > \frac{C_{out} \times V_{out} \times 0.8}{I_{ssavg}} \quad (40)$$

### 8.2.2.7 Bootstrap Capacitor Selection

A 0.1- $\mu\text{F}$  ceramic capacitor must be connected between the BOOT and PH pins for proper operation. It is recommended to use a ceramic capacitor with X5R or better grade dielectric. The capacitor should have a 10-V or higher voltage rating.

### 8.2.2.8 Undervoltage Lockout Set Point

The undervoltage lock out (UVLO) can be adjusted using an external voltage divider on the EN pin of the TPS54040-Q1. The UVLO has two thresholds, one for power up when the input voltage is rising and one for power down or brown outs when the input voltage is falling. For the example design, the supply should turn on and start switching once the input voltage increases above 8.9 V (enabled). After the regulator starts switching, it should continue to do so until the input voltage falls below 7.9 V (UVLO stop).

The programmable UVLO and enable voltages are set using a resistor divider between  $V_{IN}$  and ground to the EN pin. Equation 2 through Equation 3 can be used to calculate the resistance values necessary. For the example application, a 332 k $\Omega$  between  $V_{IN}$  and EN and a 56.2 k $\Omega$  between EN and ground are required to produce the 8.9- and 7.9-V start and stop voltages.

### 8.2.2.9 Output Voltage and Feedback Resistors Selection

For the example design, 10 k $\Omega$  was selected for R2. Using Equation 1, R1 is calculated as 52.5 k $\Omega$ . The nearest standard 1% resistor is 52.3 k $\Omega$ . Due to current leakage of the VSENSE pin, the current flowing through the feedback network should be greater than 1  $\mu$ A in order to maintain the output voltage accuracy. This requirement makes the maximum value of R2 equal to 800 k $\Omega$ . Choosing higher resistor values will decrease quiescent current and improve efficiency at low output currents but may introduce noise immunity problems.

### 8.2.2.10 Compensation

There are several methods used to compensate DC/DC regulators. The method presented here is easy to calculate and ignores the effects of the slope compensation that is internal to the device. Since the slope compensation is ignored, the actual cross over frequency will usually be lower than the cross over frequency used in the calculations. This method assume the crossover frequency is between the modulator pole and the ESR zero and the ESR zero is at least 10 times greater the modulator pole. Use SwitcherPro software for a more accurate design.

To get started, the modulator pole,  $f_{pmod}$ , and the ESR zero,  $f_{z1}$  must be calculated using Equation 41 and Equation 42. For  $C_{OUT}$ , use a derated value of 21.2  $\mu$ F. Use equations Equation 43 and Equation 44, to estimate a starting point for the crossover frequency,  $f_{co}$ , to design the compensation. For the example design,  $f_{pmod}$  is 753 Hz and  $f_{zmod}$  is 1505 kHz. Equation 43 is the geometric mean of the modulator pole and the ESR zero and Equation 44 is the mean of modulator pole and the switching frequency. Equation 43 yields 33.7 kHz and Equation 44 gives 16.2 kHz. Use the lower value of Equation 43 or Equation 44 for an initial crossover frequency. For this example,  $f_{co}$  is 16.2 kHz. Next, the compensation components are calculated. A resistor in series with a capacitor is used to create a compensating zero. A capacitor in parallel to these two components forms the compensating pole.

$$f_{p\ mod} = \frac{I_{outmax}}{2 \times \pi \times V_{out} \times C_{out}} \quad (41)$$

$$f_{z\ mod} = \frac{1}{2 \times \pi \times R_{esr} \times C_{out}} \quad (42)$$

$$f_{co} = \sqrt{f_{p\ mod} \times f_{z\ mod}} \quad (43)$$

$$f_{co} = \sqrt{f_{p\ mod} \times \frac{f_{sw}}{2}} \quad (44)$$

To determine the compensation resistor, R4, use Equation 45. Assume the power stage transconductance,  $g_{mps}$ , is 1.9A/V. The output voltage,  $V_{OUT}$ , reference voltage,  $V_{REF}$ , and amplifier transconductance,  $g_{mEA}$ , are 3.3 V, 0.8 V and 97  $\mu$ A/V, respectively. R4 is calculated to be 77.1 k $\Omega$ , use the nearest standard value of 76.8 k $\Omega$ . Use Equation 46 to set the compensation zero to the modulator pole frequency. Equation 46 yields 2754 pF for compensating capacitor C5, a 2700 pF is used on the board.

$$R4 = \left( \frac{2 \times \pi \times f_{co} \times C_{out}}{gmps} \right) \times \left( \frac{V_{out}}{V_{ref} \times gmea} \right) \quad (45)$$

$$C5 = \frac{1}{2 \times \pi \times R4 \times f_p \text{ mod}} \quad (46)$$

Use the larger value of [Equation 47](#) and [Equation 48](#) to calculate the C6, to set the compensation pole. [Equation 48](#) yields 5.9 pF so the nearest standard of 5.6 pF is used.

$$C6 = \frac{C_o \times R_{esr}}{R4} \quad (47)$$

$$C6 = \frac{1}{R4 \times f_{sw} \times \pi} \quad (48)$$

### 8.2.2.11 Discontinuous Mode and Eco-Mode Boundary

With an input voltage of 34 V, the power supply enters discontinuous mode when the output current is less than 50 mA. The power supply enters Eco-Mode when the output current is lower than 30 mA.

The input current draw at no load is 235  $\mu$ A.

## 9 Power Supply Recommendations

The TPS54040-Q1 device is designed to operate from an input voltage up to 42 V. The TPS54040-Q1 requires a high quality ceramic, type X5R or X7R, input decoupling capacitor of at least 3  $\mu\text{F}$  of effective capacitance and in some applications a bulk capacitance. Capacitance derating for aging, temperature, and DC bias must be taken into account while determining the capacitor value.

## 10 Layout

### 10.1 Layout Guidelines

Layout is a critical portion of good power supply design. There are several signals paths that conduct fast changing currents or voltages that can interact with stray inductance or parasitic capacitance to generate noise or degrade the power supplies performance. To help eliminate these problems, the VIN pin should be bypassed to ground with a low ESR ceramic bypass capacitor with X5R or X7R dielectric. Care should be taken to minimize the loop area formed by the bypass capacitor connections, the VIN pin, and the anode of the catch diode. See Figure 63 for a PCB layout example. The GND pin should be tied directly to the PowerPAD under the IC.

The PowerPAD should be connected to any internal PCB ground planes using multiple vias directly under the IC. The PH pin should be routed to the cathode of the catch diode and to the output inductor. Since the PH connection is the switching node, the catch diode and output inductor should be located close to the PH pins, and the area of the PCB conductor minimized to prevent excessive capacitive coupling. PH and Vin traces should be wide to minimize the trace inductance. For operation at full rated load, the top side ground area must provide adequate heat dissipating area. The RT/CLK pin is sensitive to noise so the RT resistor should be located as close as possible to the IC and routed with minimal lengths of trace. The additional external components can be placed approximately as shown. It may be possible to obtain acceptable performance with alternate PCB layouts, however this layout has been shown to produce good results and is meant as a guideline.

### 10.2 Layout Example

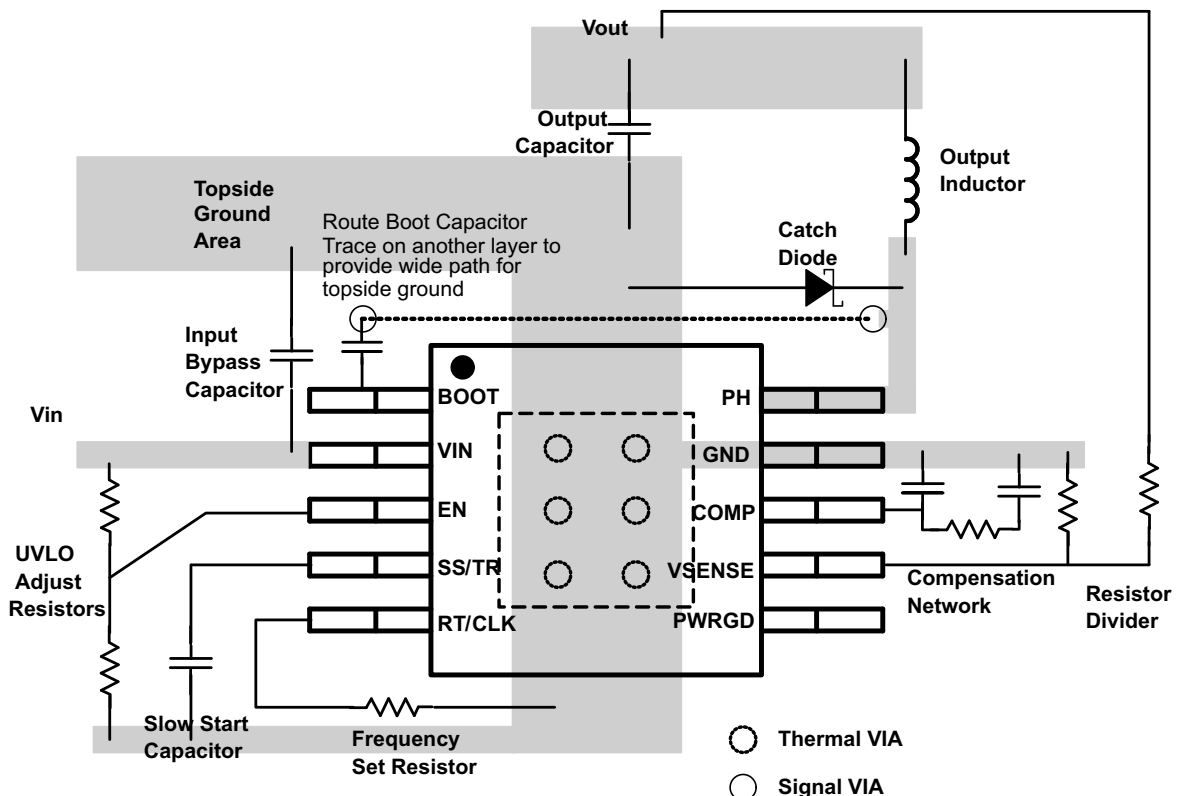

Figure 63. PCB Layout Example

### 10.3 Power Dissipation Estimate

The following formulas show how to estimate the IC power dissipation under continuous conduction mode (CCM) operation. These equations should not be used if the device is working in discontinuous conduction mode (DCM).

The power dissipation of the IC includes conduction loss ( $P_{con}$ ), switching loss ( $P_{sw}$ ), gate drive loss ( $P_{gd}$ ) and supply current ( $P_q$ ).

$$P_{con} = I_o^2 \times R_{DS(on)} \times \frac{V_{out}}{V_{in}} \quad (49)$$

$$P_{sw} = V_{in}^2 \times f_{sw} \times I_o \times 0.25 \times 10^{-9} \quad (50)$$

$$P_{gd} = V_{in} \times 3 \times 10^{-9} \times f_{sw} \quad (51)$$

$$P_q = 116 \times 10^{-6} \times V_{in} \quad (52)$$

Where:

$I_{OUT}$  is the output current (A).

$R_{DS(ON)}$  is the on-resistance of the high-side MOSFET ( $\Omega$ ).

$V_{OUT}$  is the output voltage (V).

$V_{IN}$  is the input voltage (V).

$f_{sw}$  is the switching frequency (Hz).

So

$$P_{tot} = P_{con} + P_{sw} + P_{gd} + P_q \quad (53)$$

For given  $T_A$ ,

$$T_J = T_A + R_{th} \times P_{tot} \quad (54)$$

For given  $T_{JMAX} = 150^\circ\text{C}$

$$T_{Amax} = T_{Jmax} - R_{th} \times P_{tot} \quad (55)$$

Where:

$P_{tot}$  is the total device power dissipation (W).

$T_A$  is the ambient temperature ( $^\circ\text{C}$ ).

$T_J$  is the junction temperature ( $^\circ\text{C}$ ).

$R_{th}$  is the thermal resistance of the package ( $^\circ\text{C}/\text{W}$ ).

$T_{JMAX}$  is maximum junction temperature ( $^\circ\text{C}$ ).

$T_{AMAX}$  is maximum ambient temperature ( $^\circ\text{C}$ ).

There will be additional power losses in the regulator circuit due to the inductor ac and dc losses, the catch diode and trace resistance that will impact the overall efficiency of the regulator.

### 10.4 Estimated Circuit Area

The estimated printed circuit board area for the components used in the design of [Figure 50](#) is 0.55 in<sup>2</sup>. This area does not include test points or connectors.

Estimated Circuit Area (continued)

## 12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

**PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TPS54040QDGRQ1	OBSOLETE	MSOP- PowerPAD	DGQ	10		TBD	Call TI	Call TI	-40 to 125	5404Q	

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. ## IMPORTANT NOTICE

Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (<http://www.ti.com/sc/docs/stdterms.htm>) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, "Designers") understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers' applications and compliance of their applications (and of all TI products used in or for Designers' applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers' own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
