

# **EFM32WG Reference Manual**

The EFM32 Wonder Gecko MCUs are the world's most energy-friendly microcontrollers.

The EFM32WG offers unmatched performance and ultra low power consumption in both active and sleep modes. EFM32WG devices consume as little as 0.65  $\mu A$  in Stop mode and 225  $\mu A$ /MHz in Run mode. It also features autonomous peripherals, high overall chip and analog integration, and the performance of the industry standard 32-bit ARM Cortex-M4 processor, making it perfect for battery-powered systems and systems with high-performance, low-energy requirements.

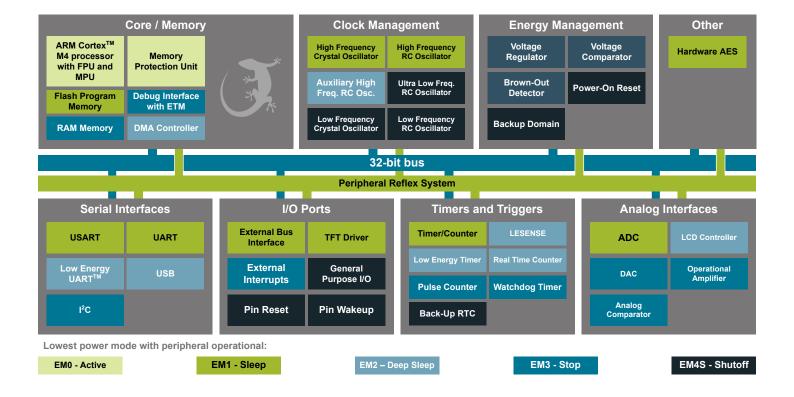

EFM32WG applications include the following:

- · Smart metering
- · Water metering
- · Gas metering

- · Industrial and home automation
- · Alarm and security systems
- · Health and fitness applications

#### **KEY FEATURES**

- · ARM Cortex-M4 at 48 MHz
- Ultra low power operation
- 0.65 μA current in Stop (EM3), with CRYOTIMER and RAM retention
- 63 µA/MHz in EM1
- 225 µA/MHz in Run mode (EM0)
- · Fast wake-up time of 2 us
- Hardware cryptography (AES)
- · Up to 256 kB of Flash and 32 kB of RAM

	10.1 Introduction	.152
	10.2 Features	.152
	10.3 Functional Description	153
	10.3.1 Energy Modes	
	10.3.2 Entering a Low Energy Mode	
	10.3.3 Leaving a Low Energy Mode	.158
	10.3.4 Backup Power Domain	.159
	10.4 Register Map	163
	10.5 Register Description	.164
	10.5.1 EMU_CTRL - Control Register	.164
	10.5.2 EMU_LOCK - Configuration Lock Register	.165
	10.5.3 EMU_AUXCTRL - Auxiliary Control Register	165
	10.5.4 EMU_EM4CONF - Energy Mode 4 Configuration Register	. 166
	10.5.5 EMU_BUCTRL - Backup Power configuration register	.167
	10.5.6 EMU_PWRCONF - Power Connection Configuration Register	
	10.5.7 EMU_BUINACT - Backup Mode Inactive Configuration Register	
	10.5.8 EMU_BUACT - Backup mode active configuration register	
	10.5.9 EMU_STATUS - Status register	
	10.5.10 EMU_ROUTE - I/O Routing Register	
	10.5.11 EMU_IF - Interrupt Flag Register	
	10.5.12 EMU_IFS - Interrupt Flag Set Register	
	10.5.13 EMU_IFC - Interrupt Flag Clear Register	
	10.5.14 EMU_IEN - Interrupt Enable Register	
	10.5.16 EMU_BUBODUNREGCAL - Unregulated power Backup BOD calibration	
11.	CMU - Clock Management Unit	
	11.1 Introduction	
	11.2 Features	
	11.3 Functional Description	
	11.3.1 System Clocks	
	11.3.2 Oscillator Selection	
	11.3.3 Oscillator Configuration	
	11.3.4 Configuration For Operating Frequencies	
	11.3.5 Output Clock on a Pin	
	11.3.6 Protection	
	11.4 Register Map	
	11.5 Register Description	
	11.5.1 CMU_CTRL - CMU Control Register	
	11.5.2 CMU_HFCORECLKDIV - High Frequency Core Clock Division Register	
	11.3.3 GIVIO TIFFEROLINDIV - HIGH FIEGUENCY FENDILEIAI GIUCK DIVISIUN KEUISIEL	. เฮโ

	11.5.4 CMU_HFRCOCTRL - HFRCO Control Register	
	11.5.5 CMU_LFRCOCTRL - LFRCO Control Register	
	11.5.6 CMU_AUXHFRCOCTRL - AUXHFRCO Control Register	
	11.5.7 CMU_CALCTRL - Calibration Control Register	
	11.5.8 CMU_CALCNT - Calibration Counter Register	
	11.5.9 CMU_OSCENCMD - Oscillator Enable/Disable Command Register	
	11.5.10 CMU_CMD - Command Register	
	11.5.11 CMU_LFCLKSEL - Low Frequency Clock Select Register	
	11.5.12 CMU_STATUS - Status Register	
	11.5.13 CMO_IF - Interrupt Flag Register	
	11.5.15 CMU_IFC - Interrupt Flag Clear Register	
	11.5.16 CMU_IEN - Interrupt Enable Register	
	11.5.17 CMU_HFCORECLKEN0 - High Frequency Core Clock Enable Register 0	
	11.5.18 CMU_HFPERCLKEN0 - High Frequency Peripheral Clock Enable Register 0	
	11.5.19 CMU_SYNCBUSY - Synchronization Busy Register	
	11.5.20 CMU_FREEZE - Freeze Register	. 211
	11.5.21 CMU_LFACLKEN0 - Low Frequency A Clock Enable Register 0 (Async Reg)	. 212
	11.5.22 CMU_LFBCLKEN0 - Low Frequency B Clock Enable Register 0 (Async Reg)	
	11.5.23 CMU_LFAPRESC0 - Low Frequency A Prescaler Register 0 (Async Reg)	
	11.5.24 CMU_LFBPRESC0 - Low Frequency B Prescaler Register 0 (Async Reg)	
	11.5.25 CMU_PCNTCTRL - PCNT Control Register	
	11.5.26 CMU_LCDCTRL - LCD Control Register	
	11.5.27 CMU_ROUTE - I/O Routing Register	
	11.5.26 CMO_LOCK - Configuration Lock Register	. 219
12.	WDOG - Watchdog Timer	. 220
	12.1 Introduction	.220
	12.2 Features	.220
	12.3 Functional Description	. 220
	12.3.1 Clock Source	. 221
	12.3.2 Debug Functionality	. 221
	12.3.3 Energy Mode Handling	. 221
	12.3.4 Register Access	. 221
	12.4 Register Map	. 221

	13.5.3 PRS_ROUTE - I/O Routing Register	
	13.5.4 PRS_CHx_CTRL - Channel Control Register	
14.	EBI - External Bus Interface	240
	14.1 Introduction	.240
	14.2 Features	.240
	14.3 Functional Description	241
	14.3.1 Non-Multiplexed 8-Bit Data, 8-Bit Address Mode	
	14.3.2 Multiplexed 16-bit Data, 16-bit Address Mode	
	14.3.3 Multiplexed 8-Bit Data, 24-Bit Address Mode	. 245
	14.3.4 Non-Multiplexed 16-Bit Data, N-Bit Address Mode	.246
	14.3.5 Page Mode Read Operation	247
	14.3.6 Extended Addressing	. 250
	14.3.7 Prefetch Unit and Write Buffer	
	14.3.8 Strobe Length	
	14.3.9 Bus Turn-Around and Idle Cycles	
	14.3.10 Timing	
	14.3.11 Data Access Width	
	14.3.12 Bank Access	
	14.3.13 WAIT/ARDY	
	14.3.15 Error Correction Code	
	14.3.16 TFT Direct Drive	
	14.3.17 Alpha Blending and Masking	
	14.3.18 Direct Drive Timing	
	14.3.19 Control Signal Polarity	
	14.3.20 Pin Configuration	
	14.3.21 Interrupts	
	14.3.22 DMA Request	. 277
	14.4 Register Map	. 278
	14.5 Register Description	.280
	14.5.1 EBI_CTRL - Control Register	. 280
	14.5.2 EBI_ADDRTIMING - Address Timing Register	. 283
	14.5.3 EBI_RDTIMING - Read Timing Register	. 284
	14.5.4 EBI_WRTIMING - Write Timing Register	
	14.5.5 EBI_POLARITY - Polarity Register	
	14.5.6 EBI_ROUTE - I/O Routing Register	
	14.5.7 EBI_ADDRTIMING1 - Address Timing Register 1	
	14.5.8 EBI_RDTIMING1 - Read Timing Register 1	
	14.5.9 EBI_WRTIMING1 - Write Timing Register 1	
	14.5.10 EBI POLARITY1 - Polarity Register 1	293

14.5.1	11 EBI_ADDRTIMING2 - Address Timing Register 2	. 294
14.5.1	2 EBI_RDTIMING2 - Read Timing Register 2	. 295
14.5.1	13 EBI_WRTIMING2 - Write Timing Register 2	. 296
14.5.1	14 EBI_POLARITY2 - Polarity Register 2	. 297
	15 EBI_ADDRTIMING3 - Address Timing Register 3	
14.5.1	16 EBI_RDTIMING3 - Read Timing Register 3	. 299
14.5.1	17 EBI_WRTIMING3 - Write Timing Register 3	. 300
14.5.1	18 EBI_POLARITY3 - Polarity Register 3	. 301
	l9 EBI_PAGECTRL - Page Control Register	
	20 EBI_NANDCTRL - NAND Control Register	
	21 EBI_CMD - Command Register	
	22 EBI_STATUS - Status Register	
	23 EBI_ECCPARITY - ECC Parity register	
	24 EBI_TFTCTRL - TFT Control Register	
	25 EBI_TFTSTATUS - TFT Status Register	
	26 EBI_TFTFRAMEBASE - TFT Frame Base Register	
	27 EBI_TFTSTRIDE - TFT Stride Register	
	28 EBI_TFTSIZE - TFT Size Register	
	29 EBI_TFTHPORCH - TFT Horizontal Porch Register	
	80 EBI_TFTVPORCH - TFT Vertical Porch Register	
	31 EBI_TFTTIMING - TFT Timing Register	
	32 EBI_TFTPOLARITY - TFT Polarity Register	
	33 EBI_TFTDD - TFT Direct Drive Data Register	
	34 EBI_TFTALPHA - TFT Alpha Blending Register	
	85 EBI_TFTPIXEL0 - TFT Pixel 0 Register	
	36 EBI_TFTPIXEL1 - TFT Pixel 1 Register	
	37 EBI_TFTPIXEL - TFT Alpha Blending Result Pixel Register	
	88 EBI_TFTMASK - TFT Masking Register

16.3.1	<sup>2</sup> C-Bus Overview		538

16.3.2 Enable and Reset	542
16.3.3 Safely Disabling and Changing Slave Configuration	. 542
16.3.4 Clock Generation	543
16.3.5 Arbitration	544
16.3.6 Buffers	545
16.3.7 Master Operation	
16.3.8 Bus States	
16.3.9 Slave Operation	
16.3.10 Transfer Automation	
16.3.11 Using 10-Bit Addresses	
16.3.12 Error Handling	
16.3.13 DMA Support	
16.3.14 Interrupts	
16.3.15 Wake-Up	
16.4 Register Map	. 560
16.5 Register Description	561
16.5.1 I2Cn_CTRL - Control Register	
16.5.2 I2Cn_CMD - Command Register	
16.5.3 I2Cn_STATE - State Register	
16.5.4 I2Cn_STATUS - Status Register	
16.5.5 I2Cn_CLKDIV - Clock Division Register	
16.5.6 I2Cn_SADDR - Slave Address Register	
16.5.7 I2Cn_SADDRMASK - Slave Address Mask Register	
16.5.8 I2Cn_RXDATAR Receive Buffer Data Register (Actionable Reads)	
16.5.9 I2Cn_RXDATAP - Receive Buffer Data Peek Register	
16.5.11 I2Cn_IF - Interrupt Flag Register	
16.5.12 I2Cn_IFS - Interrupt Flag Set Register	
16.5.13 I2Cn IFC - Interrupt Flag Clear Register	
16.5.14 I2Cn_IEN - Interrupt Enable Register	
16.5.15 I2Cn_ROUTE - I/O Routing Register	
17. USART - Universal Synchronous Asynchronous Receiver/Transmitter	
17.1 Introduction	578
17.2 Features	579
17.3 Functional Description	. 580
17.3.1 Modes of Operation	. 581
17.3.2 Asynchronous Operation	582
17.3.3 Synchronous Operation	597
17.3.4 PRS-Triggered Transmissions	603
17.3.5 PRS RX Input	. 604
17.3.6 DMA Support	. 604
17.3.7 Transmission Delay	
17.3.8 Interrupts	
17.3.9 IrDA Modulator/Demodulator	. 606
17.4 Register Map	. 607
17.5 Register Description	608

	17.5.1 USARTn_CTRL - Control Register	. 000
	17.5.2 USARTn_FRAME - USART Frame Format Register	. 613
	17.5.3 USARTn_TRIGCTRL - USART Trigger Control register	
	17.5.4 USARTn_CMD - Command Register	
	17.5.5 USARTn_STATUS - USART Status Register	
	17.5.6 USARTn_CLKDIV - Clock Control Register	
	17.5.7 USARTn_RXDATAX - RX Buffer Data Extended Register (Actionable Reads)	
	17.5.8 USARTn_RXDATA - RX Buffer Data Register (Actionable Reads)	
	17.5.9 USARTn_RXDOUBLEX - RX Buffer Double Data Extended Register (Actionable Reads)	
	17.5.10 USARTn_RXDOUBLE - RX FIFO Double Data Register (Actionable Reads)	
	17.5.11 USARTn_RXDATAXP - RX Buffer Data Extended Peek Register	
	17.5.12 USARTn_RXDOUBLEXP - RX Buffer Double Data Extended Peek Register	
	17.5.13 USARTII_TADATAA - TA Bullet Data Extended Register	
	17.5.14 USARTn_TXDATA - TX Buffer Double Data Extended Register	
	17.5.16 USARTn_TXDOUBLE - TX Buffer Double Data Register	
	17.5.17 USARTn IF - Interrupt Flag Register	
	17.5.18 USARTn IFS - Interrupt Flag Set Register	
	17.5.19 USARTn IFC - Interrupt Flag Clear Register	
	17.5.20 USARTn_IEN - Interrupt Enable Register	
	17.5.21 USARTn_IRCTRL - IrDA Control Register	
	17.5.22 USARTn ROUTE - I/O Routing Register	
	17.5.23 USARTn_INPUT - USART Input Register	.634
	17.5.24 USARTn_I2SCTRL - I2S Control Register	
18.	. UART - Universal Asynchronous Receiver/ Transmitter	. 637

	19.3.12 Register Access	650
	19.4 Register Map	. 651
	19.5 Register Description	652
	19.5.1 LEUARTn_CTRL - Control Register (Async Reg)	
	19.5.2 LEUARTn_CMD - Command Register (Async Reg)	
	19.5.3 LEUARTn_STATUS - Status Register	
	19.5.4 LEUARTn_CLKDIV - Clock Control Register (Async Reg)	
	19.5.5 LEUARTn_STARTFRAME - Start Frame Register (Async Reg)	
	19.5.6 LEUARTn_SIGFRAME - Signal Frame Register (Async Reg)	658
	19.5.7 LEUARTn_RXDATAX - Receive Buffer Data Extended Register (Actionable Reads)	658
	19.5.8 LEUARTn_RXDATA - Receive Buffer Data Register (Actionable Reads)	659
	19.5.9 LEUARTn_RXDATAXP - Receive Buffer Data Extended Peek Register	. 659
	19.5.10 LEUARTn_TXDATAX - Transmit Buffer Data Extended Register (Async Reg)	660
	19.5.11 LEUARTn_TXDATA - Transmit Buffer Data Register (Async Reg)	661
	19.5.12 LEUARTn_IF - Interrupt Flag Register	
	19.5.13 LEUARTn_IFS - Interrupt Flag Set Register	. 663
	19.5.14 LEUARTn_IFC - Interrupt Flag Clear Register	
	19.5.15 LEUARTn_IEN - Interrupt Enable Register	
	19.5.16 LEUARTn_PULSECTRL - Pulse Control Register (Async Reg)	
	19.5.17 LEUARTn_FREEZE - Freeze Register	
	19.5.18 LEUARTn_SYNCBUSY - Synchronization Busy Register	
	19.5.19 LEUARTn_ROUTE - I/O Routing Register	
	19.5.20 LEUARTn_INPUT - LEUART Input Register	670
20	. TIMER - Timer/Counter	671
	20.1 Introduction	671
	20.2 Features	672
	20.3 Functional Description	673
	20.3.1 Counter Modes	
	20.3.2 Compare/Capture Channels	
	20.3.3 Dead-Time Insertion Unit (TIMER0 only)	
	20.3.4 Debug Mode	
	20.3.5 Interrupts, DMA and PRS Output	
	20.3.6 GPIO Input/Output	
	20.4 Register Map	. 692
	20.5 Register Description	693
	20.5.1 TIMERn CTRL - Control Register	
	20.5.2 TIMERn CMD - Command Register	
	20.5.3 TIMERn_STATUS - Status Register	
	20.5.4 TIMERn_IEN - Interrupt Enable Register	
	20.5.5 TIMERn IF - Interrupt Flag Register	
	20.5.6 TIMERn_IFS - Interrupt Flag Set Register	. 701
	20.5.7 TIMERn_IFC - Interrupt Flag Clear Register	
	20.5.8 TIMERn_TOP - Counter Top Value Register	
	20.5.9 TIMERn_TOPB - Counter Top Value Buffer Register	
	20.5.10 TIMERn_CNT - Counter Value Register	
	20.5.11 TIMERn_ROUTE - I/O Routing Register	

	20.5.12 TIMERn_CCx_CTRL - CC Channel Control Register	706
	20.5.13 TIMERn_CCx_CCV - CC Channel Value Register	.709
	20.5.14 TIMERn_CCx_CCVP - CC Channel Value Peek Register	. 709
	20.5.15 TIMERn_CCx_CCVB - CC Channel Buffer Register	
	20.5.16 TIMERn_DTCTRL - DTI Control Register	.711
	20.5.17 TIMERn_DTTIME - DTI Time Control Register	713
	20.5.18 TIMERn_DTFC - DTI Fault Configuration Register	.715
	20.5.19 TIMERn_DTOGEN - DTI Output Generation Enable Register	
	20.5.20 TIMERn_DTFAULT - DTI Fault Register	7.18
	20.5.21 TIMERn_DTFAULTC - DTI Fault Clear Register	. 719
	20.5.22 TIMERn_DTLOCK - DTI Configuration Lock Register	
04	DTO Deal Time Counter	704
21.	RTC - Real Time Counter	721
	21.1 Introduction	
	21.2 Features	.721
	21.3 Functional Description	7.22
	21.3.1 Counter	722
	21.3.2 Compare Channels	723
	21.3.3 Interrupts	. 724
	21.3.4 DEBUGRUN	. 724
	21.3.5 Using the RTC in EM3	724
	21.3.6 Register Access	724
	21.4 Register Map	724
	21.5 Register Description	.725
	21.5.1 RTC_CTRL - Control Register (Async Reg)	
	21.5.2 RTC_CNT - Counter Value Register	
	21.5.3 RTC_COMP0 - Compare Value Register 0 (Async Reg)	
	21.5.4 RTC COMP1 - Compare Value Register 1 (Async Reg)	
	21.5.5 RTC IF - Interrupt Flag Register	
	21.5.6 RTC_IFS - Interrupt Flag Set Register	
	21.5.7 RTC_IFC - Interrupt Flag Clear Register	
	21.5.8 RTC IEN - Interrupt Enable Register	
	21.5.9 RTC_FREEZE - Freeze Register	
	21.5.10 RTC SYNCBUSY - Synchronization Busy Register	
22	BURTC - Backup Real Time Counter	
<b></b> _	22.1 Introduction	
	22.2 Features	
	22.3 Functional Description	
	·	
	22.3.2 Clock Source	
	22.3.3 Compare Channel	
	22.3.5 Debug Run	
	22.3.6 Low Power Mode	
	22.3.7 Retention Registers	. 733
	ZZ S O DRUKUD UDERBUON	. / 33

	22.3.9 Backup Mode Timestamp	. 734
	22.3.10 LFXO Failure Detection	. 734
	22.3.11 Register Access	734
	22.4 Register Map	. 735
	22.5 Register Description	736
	22.5.1 BURTC CTRL - Control Register	
	22.5.2 BURTC_LPMODE - Low power mode configuration (Async Reg)	
	22.5.3 BURTC CNT - Counter Value Register	
	22.5.4 BURTC_COMP0 - Counter Compare Value (Async Reg)	
	22.5.5 BURTC_TIMESTAMP - Backup mode timestamp	
	22.5.6 BURTC_LFXOFDET - LFXO	
	22.5.7 BURTC_STATUS - Status Register	
	22.5.8 BURTC_CMD - Command Register	
	22.5.9 BURTC_POWERDOWN - Retention RAM power-down Register	
	22.5.10 BURTC_LOCK - Configuration Lock Register	
	22.5.11 BURTC_IF - Interrupt Flag Register	
	22.5.12 BURTC_IFS - Interrupt Flag Set Register	
	22.5.13 BURTC IFC - Interrupt Flag Clear Register	
	22.5.14 BURTC_IEN - Interrupt Enable Register	
	22.5.15 BURTC_FREEZE - Freeze Register	
	22.5.16 BURTC_SYNCBUSY - Synchronization Busy Register	
	22.5.17 RETx_REG - Retention Register	
23	. LETIMER - Low Energy Timer	
	23.1 Introduction	747
	23.2 Features	747
	23.3 Functional Description	. 7.48
	23.3.1 Timer	
	23.3.2 Compare Registers	
	23.3.3 Top Value	
	23.3.4 Underflow Output Action	
	23.3.5 PRS Output	
	23.3.6 Examples	
	23.3.7 Using the LETIMER in EM3	
	23.3.8 Register Access	
	23.4 Register Map	
	23.5 Register Description	
	23.5.1 LETIMERn CTRL - Control Register (Async Reg)	
	23.5.2 LETIMERI_CMD - Command Register	
	23.5.3 LETIMERI_CIMD - Command Register	
	23.5.4 LETIMERn_CNT - Counter Value Register	
	23.5.5 LETIMERI_COMP0 - Compare Value Register 0 (Async Reg)	
	23.5.6 LETIMERI_COMP0 - Compare Value Register 1 (Async Reg)	
	<del>-</del>	
	23.5.7 LETIMERn_REP0 - Repeat Counter Register 0 (Async Reg)	
	23.5.9 LETIMERn_IF - Interrupt Flag Register	
	za a iv. Te umenu iea - inienum eidu aei reusiei	700

	23.5.11 LETIMERn_IFC - Interrupt Flag Clear Register	767
	23.5.12 LETIMERn_IEN - Interrupt Enable Register	
	23.5.13 LETIMERn_FREEZE - Freeze Register	. 769
	23.5.14 LETIMERn_SYNCBUSY - Synchronization Busy Register	
	23.5.15 LETIMERn_ROUTE - I/O Routing Register	. 771
24.	PCNT - Pulse Counter	7.72
	24.1 Introduction	
	24.2 Features	
	24.3 Functional Description	
	24.3.1 Pulse Counter Modes	
	24.3.2 Hysteresis	
	24.3.3 Auxiliary Counter	
	24.3.4 Register Access	
	24.3.5 Clock Sources	
	24.3.6 Input Filter	
	24.3.7 Edge Polarity	
	24.3.8 PRS S0IN and S1IN Input	
	24.3.9 Interrupts	
	24.4 Register Map	
	24.5 Register Description	
	24.5.1 PCNTn_CTRL - Control Register (Async Reg)	
	24.5.2 PCNTn_CMD - Command Register (Async Reg)	
	24.5.3 PCNTn_STATUS - Status Register	
	24.5.4 PCNTn_CNT - Counter Value Register	
	24.5.5 PCNTn_TOP - Top Value Register	
	24.5.6 PCNTn_TOPB - Top Value Buffer Register (Async Reg)	
	24.5.7 PCNTn_IF - Interrupt Flag Register	
	24.5.8 PCNTn_IFS - Interrupt Flag Set Register	
	24.5.9 PCNTn_IFC - Interrupt Flag Clear Register	
	24.5.10 PCNTn_IEN - Interrupt Enable Register	
	24.5.11 PCNTn_ROUTE - I/O Routing Register	
	24.5.12 PCNTn_FREEZE - Freeze Register	
	24.5.13 PCNTn_SYNCBUSY - Synchronization Busy Register	
	24.5.14 PCNTn_AUXCNT - Auxiliary Counter Value Register	
	24.5.15 PCNTn_INPUT - PCNT Input Register	.790
25.	LESENSE - Low Energy Sensor Interface	792
	25.1 Introduction	.792
	25.2 Features	.792
	25.3 Functional Description	7.93
	25.3.1 Channel Configuration	794
	25.3.2 Scan Sequence	
	25.3.3 Sensor Timing	.796
	25.3.4 Sensor Interaction	
	25.3.5 Sensor Evaluation	. 799
	25.3.6 Decoder	.800

25.3.7 Measurement Results	803
25.3.8 DAC Interface	. 804
25.3.9 ACMP Interface	804
25.3.10 ACMP and DAC Duty Cycling	
25.3.11 DMA Requests	
25.3.12 PRS Output	
25.3.13 RAM	
25.3.14 Application Examples	. 805
25.4 Register Map	810
25.5 Register Description	
25.5.1 LESENSE_CTRL - Control Register (Async Reg)	
25.5.2 LESENSE_TIMCTRL - Timing Control Register (Async Reg)	
25.5.3 LESENSE_PERCTRL - Peripheral Control Register (Async Reg)	
25.5.4 LESENSE_DECCTRL - Decoder control Register (Async Reg)	
25.5.5 LESENSE_BIASCTRL - Bias Control Register (Async Reg)	
25.5.6 LESENSE_CMD - Command Register	
25.5.7 LESENSE_CHEN - Channel enable Register (Async Reg)	
25.5.8 LESENSE_SCANRES - Scan result register (Async Reg)	
25.5.9 LESENSE_STATUS - Status Register (Async Reg)	
25.5.10 LESENSE_PTR - Result buffer pointers (Async Reg)	
25.5.11 LESENSE_BUFDATA - Result buffer data register (Async Reg) (Actionable Reads)	
25.5.12 LESENSE_CURCH - Current channel index (Async Reg)	
25.5.13 LESENSE_DECSTATE - Current decoder state (Async Reg)	
25.5.14 LESENSE_SENSORSTATE - Decoder input register (Async Reg)	
25.5.15 LESENSE_IDLECONF - GPIO Idle phase configuration (Async Reg)	
25.5.17 LESENSE IF - Interrupt Flag Register	
25.5.18 LESENSE IFC - Interrupt Flag Clear Register	
25.5.19 LESENSE IFS - Interrupt Flag Set Register	
25.5.20 LESENSE IEN - Interrupt Enable Register	
25.5.21 LESENSE_SYNCBUSY - Synchronization Busy Register	
25.5.22 LESENSE_ROUTE - I/O Routing Register (Async Reg)	
25.5.23 LESENSE_POWERDOWN - LESENSE RAM power-down register (Async Reg) .	
25.5.24 LESENSE_STx_TCONFA - State transition configuration A (Async Reg)	849
25.5.25 LESENSE_STx_TCONFB - State transition configuration B (Async Reg)	851
25.5.26 LESENSE_BUFx_DATA - Scan results (Async Reg)	852
25.5.27 LESENSE_CHx_TIMING - Scan configuration (Async Reg)	853
25.5.28 LESENSE_CHx_INTERACT - Scan configuration (Async Reg)	854
25.5.29 LESENSE_CHx_EVAL - Scan configuration (Async Reg)	856
26. ACMP - Analog Comparator	. 857
26.1 Introduction	857
26.2 Features	857
26.3 Functional Description	858
26.3.1 Warm-up Time	858
26.3.2 Response Time	859
26.3.3. Hysteresis	860

	26.3.4 Input Selection	861
	26.3.7 Output to GPIO	
	26.4 Register Map	862
	26.5.1 ACMPn_CTRL - Control Register 26.5.2 ACMPn_INPUTSEL - Input Selection Register 26.5.3 ACMPn_STATUS - Status Register 26.5.4 ACMPn_IEN - Interrupt Enable Register 26.5.5 ACMPn_IF - Interrupt Flag Register 26.5.6 ACMPn_IFS - Interrupt Flag Set Register 26.5.7 ACMPn_IFC - Interrupt Flag Clear Register 26.5.8 ACMPn_ROUTE - I/O Routing Register	863 865 867 867 868 868 869
27.	VCMP - Voltage Comparator	.870
	27.1 Introduction	.870
	27.2 Features	.870
	27.3 Functional Description          27.3.1 Warm-Up Time          27.3.2 Response Time          27.3.3 Hysteresis          27.3.4 Input Selection          27.3.5 Interrupts and PRS Output	871 872 873 873
	27.4 Register Map	874
	27.5 Register Description 27.5.1 VCMP_CTRL - Control Register 27.5.2 VCMP_INPUTSEL - Input Selection Register 27.5.3 VCMP_STATUS - Status Register 27.5.4 VCMP_IEN - Interrupt Enable Register 27.5.5 VCMP_IF - Interrupt Flag Register 27.5.6 VCMP_IFS - Interrupt Flag Set Register 27.5.7 VCMP_IFC - Interrupt Flag Clear Register	875 876 877 877 878 878
28.	ADC - Analog to Digital Converter	880
	28.1 Introduction	.880 .881
	28.3 Functional Description	882 883 884 885 .886

# 1. Energy Friendly Microcontrollers

# 1.1 Typical Applications

The EFM32WG Wonder Gecko is the ideal choice for demanding 8-, 16-, and 32-bit energy sensitive applications. These devices are developed to minimize the energy consumption by lowering both the power and the active time, over all phases of MCU operation. This unique combination of ultra low energy consumption and the performance of the 32-bit ARM Cortex-M4 processor helps designers get more out of the available energy in a variety of applications.

# Ultra low energy EFM32WG microcontrollers are perfect for:

- · Gas metering
- · Energy metering
- · Water metering
- · Smart metering
- · Alarm and security systems
- · Health and fitness applications
- · Industrial and home automation

# 1.2 EFM32WG Development

Because EFM32WG use the Cortex-M4 CPU, embedded designers benefit from the largest development ecosystem in the industry, the ARM ecosystem. The development suite spans the whole design process and includes powerful debug tools, and some of the world's top brand compilers. Libraries with documentation and user examples shorten time from idea to market.

The range of EFM32WG devices ensure easy migration and feature upgrade possibilities.

# 2. About This Document

This document contains reference material for the EFM32WG series of microcontrollers. All modules and peripherals in the EFM32WG series devices are described in general terms. Not all modules are present in all devices, and the feature set for each device might vary. Such differences, including pinout, are covered in the device-specific datasheet.

# 2.1 Conventions

# **Register Names**

Register names are given as a module name prefix followed by the short register name:

TIMERn\_CTRL - Control Register

The "n" denotes the numeric instance for modules that might have more than one instance.

Some registers are grouped which leads to a group name following the module prefix:

GPIO\_Px\_DOUT - Port Data Out Register,

where x denotes the port instance (A,B,...).

#### **Bit Fields**

Registers contain one or more bit fields which can be 1 to 32 bits wide. Multi-bit fields are denoted with (x:y), where x is the start bit and y is the end bit.

#### **Address**

The address for each register can be found by adding the base address of the module (found in the Memory Map), and the offset address for the register (found in module Register Map).

### **Access Type**

The register access types used in the register descriptions are explained in the table below.

**Table 2.1. Register Access Types** 

Access Type	Description						
R	Read only. Writes are ignored.						
RW	Readable and writable.						
RW1	Readable and writable. Only writes to 1 have effect.						
RW1H	Readable, writable and updated by hardware. Only writes to 1 have effect.						
W1	Read value undefined. Only writes to 1 have effect.						
W	Write only. Read value undefined.						
RWH	Readable, writable and updated by hardware.						

#### **Number format**

0x prefix is used for hexadecimal numbers.

**0b** prefix is used for binary numbers.

Numbers without prefix are in decimal representation.

#### Reserved

Registers and bit fields marked with reserved are reserved for future use. These should be written to 0 unless otherwise stated in the Register Description. Reserved bits might be read as 1 in future devices.

# **Reset Value**

The reset value denotes the value after reset. Registers denoted with X have an unknown reset value and need to be initialized before use. Note that, before these registers are initialized, read-modify-write operations might result in undefined register values.

#### **Pin Connections**

Pin connections are given as a module prefix followed by a short pin name:

USn\_TX (USARTn TX pin)

The pin locations referenced in this document are given in the device-specific datasheet.

#### 2.2 Related Documentation

Further documentation on the EFM32WG family and the ARM Cortex-M4 can be found at the Silicon Laboratories and ARM web pages:

# 3. System Overview

# 3.1 Introduction

The EFM32 MCUs are the world's most energy friendly microcontrollers. With a unique combination of the powerful 32-bit ARM Cortex-M4, innovative low energy techniques, short wake-up time from energy saving modes, and a wide selection of peripherals, the EFM32WG microcontroller is well suited for any battery operated application, as well as other systems requiring high performance and low-energy consumption. See Figure 3.1 Block Diagram of EFM32WG on page 30 for a block diagram of the EFM32WG device.

#### 3.2 Features

# · ARM Cortex-M4 CPU platform

- · High Performance 32-bit processor @ up to 48 MHz
- · DSP instruction support and floating-point unit
- · Memory Protection Unit
- · Wake-up Interrupt Controller

# Flexible Energy Management System

- · 20 nA @ 3 V Shutoff Mode
- 0.4 μA @ 3 V Shutoff Mode with RTC
- 0.65 μA @ 3 V Stop Mode, including Power-on Reset, Brown-out Detector, RAM and CPU retention
- 0.95 μA @ 3 V Deep Sleep Mode, including RTC with 32.768 kHz oscillator, Power-on Reset, Brown-out Detector, RAM and CPU retention
- 63 μA/MHz @ 3 V Sleep Mode
- 225 μA/MHz @ 3 V Run Mode, with code executed from flash
- · 256/128/64 KB Flash
- 32 KB RAM

# Up to 93 General Purpose I/O pins

- · Configurable push-pull, open-drain, pull-up/down, input filter, drive strength
- · Configurable peripheral I/O locations
- · 16 asynchronous external interrupts
- · Output state retention and wake-up from Shutoff Mode

# 12 Channel DMA Controller

Alternate/primary descriptors with scatter-gather/ping-pong operation

#### 12 Channel Peripheral Reflex System

Autonomous inter-peripheral signaling enables smart operation in low energy modes

#### · External Bus Interface (EBI)

- Up to 4x256 MB of external memory mapped space
- · TFT Controller supporting Direct Drive

### Universal Serial Bus (USB) with Host and OTG support

- · Fully USB 2.0 compliant
- · On-chip PHY and embedded 5V to 3.3V regulator

# • Integrated LCD Controller for up to 8×36 Segments

- · Voltage boost, adjustable contrast adjustment and autonomous animation feature
- Hardware AES with 128/256-bit Keys in 54/75 cycles
- · Communication Interfaces
  - 3× Universal Synchronous/Asynchronous Receiver/Transmitter
    - UART/SPI/SmartCard (ISO 7816)/IrDA (USART0)/I2S (USART1+USART2)
    - Triple buffered full/half-duplex operation
    - 4-16 data bits
  - · 2× Universal Asynchronous Receiver/Transmitter
    - Triple buffered full/half-duplex operation
    - · 8-9 data bits
  - 2× Low Energy UART
    - · Autonomous operation with DMA in Deep Sleep Mode
  - 2× I<sup>2</sup>C Interface with SMBus support
    - · Address recognition in Stop Mode

#### Timers/Counters

- 4×16-bit Timer/Counter
  - 3 Compare/Capture/PWM channels
  - · Dead-Time Insertion on TIMER0
- · 16-bit Low Energy Timer
- 1× 24-bit and 1× 32-bit Real-Time Counter

- · 3× 16-bit Pulse Counter
  - · Asynchronous pulse counting/quadrature decoding
- · Watchdog Timer with dedicated RC oscillator @ 50 nA

# · Backup Power Domain

- · RTC and retention registers in a separate power domain, available in all energy modes
- · Operation from backup battery when main power drains out

# Ultra Low Power Precision Analog Peripherals

- 12-bit 1 Msamples/s Analog to Digital Converter
  - · 8 input channels and on-chip temperature sensor
  - · Single ended or differential operation
  - · Conversion tailgating for predictable latency
- · 12-bit 500 ksamples/s Digital to Analog Converter
  - 2 single ended channels/1 differential channel
- · Up to 3 Operational Amplifiers
  - · Supports rail-to-rail inputs and outputs
  - · Programmable gain
- 2× Analog Comparator
  - · Programmable speed/current
  - · Capacitive sensing with up to 8 inputs
- · Supply Voltage Comparator

# · Ultra Low Power Sensor Interface

- · Autonomous sensor monitoring in Deep Sleep Mode
- · Wide range of sensors supported, including LC sensors and capacitive buttons

# • Ultra Efficient Power-on Reset and Brown-Out Detector

# · Debug Interface

- · 2-pin Serial Wire Debug interface
  - · 1-pin Serial Wire Viewer
- Embedded Trace Module v3.5 (ETM)
- Temperature range -40 85°C
- Single power supply 1.98 3.8 V

# Packages

- QFN64
- TQFP64
- LQFP100
- LFBGA112
- VFBGA120

#### 3.3 Block Diagram

Figure 3.1 Block Diagram of EFM32WG on page 30 shows the block diagram of EFM32WG. The color indicates peripheral availability in the different energy modes, described in 3.4 Energy Modes .

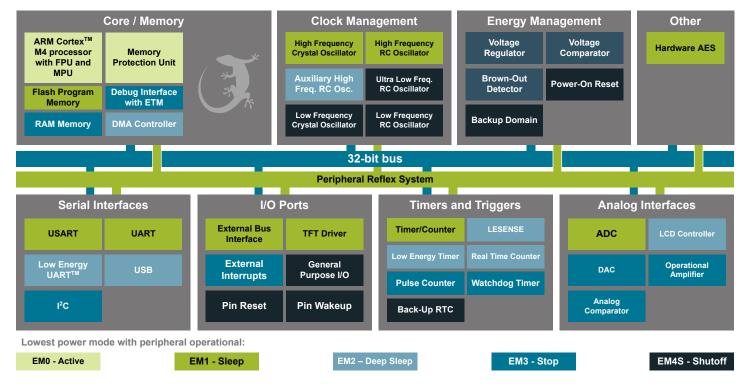

Figure 3.1. Block Diagram of EFM32WG

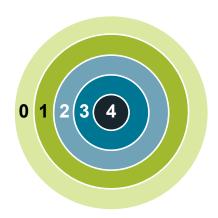

Figure 3.2. Energy Mode Indicator

Note: In the energy mode indicator, the numbers indicates Energy Mode, i.e EM0-EM4.

#### 3.4 Energy Modes

There are five different Energy Modes (EM0-EM4) in the EFM32WG, see Table 3.1 Energy Mode Description on page 31. The EFM32WG is designed to achieve a high degree of autonomous operation in low energy modes. The intelligent combination of peripherals, RAM with data retention, DMA, low-power oscillators, and short wake-up time, makes it attractive to remain in low energy modes for long periods and thus saving energy consumption.

**Note:** Throughout this document, the first figure in every module description contains an Energy Mode Indicator showing which energy mode(s) the module can operate.

Table 3.1. Energy Mode Description

Energy Mode	Name	Description
0 1 2 3 4	EM0 - Energy Mode 0 (Run mode)	In EM0, the CPU is running and consuming as little as 225 µA/MHz, when running code from flash. All peripherals can be active.
0 1 2 3 4	EM1 - Energy Mode 1 (Sleep Mode)	In EM1, the CPU is sleeping and the power consumption is only 63 μA/MHz. All peripherals, including DMA, PRS and memory system, are still available.
0 1 2 3 4	EM2 - Energy Mode 2 (Deep Sleep Mode)	In EM2 the high frequency oscillator is turned off, but with the 32.768 kHz oscillator running, selected low energy peripherals (LCD, RTC, LETIMER, PCNT, LEUART, I2C, LESENSE, OPAMP, USB, WDOG and ACMP) are still available. This gives a high degree of autonomous operation with a current consumption as low as 0.95 µA with RTC enabled. Power-on Reset, Brownout Detection and full RAM and CPU retention is also included.
0 1 2 3 4	EM3 - Energy Mode 3 (Stop Mode)	In EM3, the low-frequency oscillator is disabled, but there is still full CPU and RAM retention, as well as Power-on Reset, Pin reset, EM4 wake-up and Brown-out Detection, with a consumption of only 0.65 $\mu A$ . The low-power ACMP, asynchronous external interrupt, PCNT, and I2C can wake-up the device. Even in this mode, the wake-up time is a few microseconds.
0 1 2 3 4	EM4 - Energy Mode 4 (Shutoff Mode)	In EM4, the current is down to 20 nA and all chip functionality is turned off except the pin reset, GPIO pin wake-up, GPIO pin retention, Backup RTC (including retention RAM) and the Power-On Reset. All pins are put into their reset state.

# 3.5 Product Overview

The following table shows a device overview of the EFM32WG Microcontroller Series, including peripheral functionality. For more information, the reader is referred to the device specific datasheets.

#### Note:

1. EBI and LCD share pins in the part. Only a reduced pin count LCD driver can be used simultaneously with the EBI.

#### 3.6 Device Revision

The device revision number is read from the ROM Table. The major revision number and the chip family number is read from PID0 and PID1 registers. The minor revision number is extracted from the PID2 and PID3 registers, as illustrated in Figure 3.3 Revision Number Extraction on page 35. The Fam[5:2] and Fam[1:0] must be combined to complete the chip family number, while the Minor Rev[7:4] and Minor Rev[3:0] must be combined to form the complete revision number.

	PID2 (0xE	00FFFE8)			PID3 (0xE00FFF	EC)	
31:8	7:	4	3:0	31:8	7:4		3:0
	Minor R	ev[7:4]			Minor Rev[3:0	)]	
	PID0 (0xE	00FFFE0)			PID1 (0xE00FFF	E4)	
31:8	7:6	5:0			31:4	3	:0
	Fam[1:0]	Major Re	v[5:0]			Fam	[5:2]

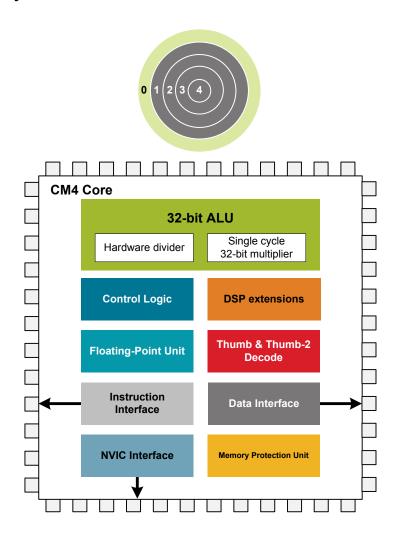

Figure 3.3. Revision Number Extraction

For the latest revision of the Wonder Gecko family, the chip family number is 0x03 and the major revision number is 0x01. The minor revision number is to be interpreted according to the table below.

**Table 3.3. Minor Revision Number Interpretation** 

Minor Rev[7:0]	Revision
0x00	A

# 4. System Processor

#### **Quick Facts**

#### What?

The industry leading Cortex-M4 processor from ARM is the CPU in the EFM32WG microcontrollers.

#### Why?

The ARM Cortex-M4 is designed for exceptional short response time, high code density, and high 32-bit throughput while maintaining a strict cost and power consumption budget.

#### How?

Combined with the ultra low energy peripherals available, the Cortex-M4 with Floating-Point Unit (FPU) makes the EFM32WG devices perfect for 8-to 32- bit applications. The processor is featuring a Harvard architecture, 3 stage pipeline, single cycle instructions, extended Thumb-2 instruction set support, and fast interrupt handling.

# 4.1 Introduction

The ARM Cortex-M4 32-bit RISC processor provides outstanding computational performance and exceptional system response to interrupts while meeting low cost requirements and low power consumption.

The ARM Cortex-M4 implemented is revision r0p1.

#### 4.2 Features

- · Digital Signal Processor
  - · Enhances speed and reduces the active time with dedicated DSP instructions
- · Harvard Architecture
  - · Separate data and program memory buses (No memory bottleneck as for a single-bus system)
- · 3-stage pipeline
- · Thumb-2 instruction set
  - · Enhanced levels of performance, energy efficiency, and code density
- · Single-Precision Floating-Point Unit
  - · Enables embedded system designers to take full advantage of floating-points
  - · Extends the instruction set with 28 floating-point instructions
- · Single-cycle multiply and efficient divide instructions
  - · 32-bit multiplication in a single cycle
  - · Signed and unsigned divide operations between 2 and 12 cycles
- · Atomic bit manipulation with bit banding
  - · Direct access to single bits of data
  - Two 1MB bit banding regions for memory and peripherals mapping to 32MB alias regions
  - · Atomic operation which cannot be interrupted by other bus activities
- 1.25 DMIPS/MHz
- · Memory Protection Unit
  - · Up to 8 protected memory regions
- 24-bit System Tick Timer for Real-Time Operating System (RTOS)
- · Excellent 32-bit migration choice for 8/16 bit architecture based designs
  - Simplified stack-based programmer's model is compatible with traditional ARM architecture and retains the programming simplicity of legacy 8- and 16-bit architectures
- · Unaligned data storage and access
  - · Continuous storage of data requiring different byte lengths
  - · Data access in a single core clock cycle
- · Integrated power modes
  - · Sleep Now mode for immediate transfer to low power state
  - · Sleep on Exit mode for entry into low power state after the servicing of an interrupt
  - · Ability to extend power savings to other system components
- · Optimized for low latency, nested interrupts

### 4.3 Functional Description

For a full functional description of the ARM Cortex-M4 (r0p1) implementation in the EFM32WG family, the reader is referred to the ARM Cortex-M4 Devices Generic User Guide.

## 4.3.1 Interrupt Operation

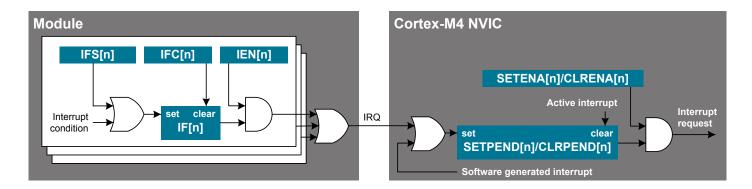

Figure 4.1. Interrupt Operation

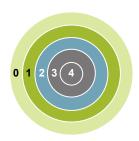

The EFM32WG devices have up to 40 interrupt request lines (IRQ) which are connected to the Cortex-M4. Each of these lines are connected to one or more interrupt flags in one or more modules. The interrupt flags are set by hardware on an interrupt condition. It is also possible to set/clear the interrupt flags through the IFS/IFC registers. Each interrupt flag is then qualified with its own interrupt enable bit (IEN register), before being OR'ed with the other interrupt flags to generate the IRQ. A high IRQ line will set the corresponding pending bit (can also be set/cleared with the SETPEND/CLRPEND bits in ISPR0/ICPR0) in the Cortex-M4 NVIC. The pending bit is then qualified with an enable bit (set/cleared with SETENA/CLRENA bits in ISER0/ICER0) before generating an interrupt request to the core. The previous figure illustrates the interrupt system. For more information on how the interrupts are handled inside the Cortex-M4, the reader is referred to the ARM Cortex-M4 Devices Generic User Guide.

# 5. Memory and Bus System

### **Quick Facts**

### What?

A low latency memory system, including low energy flash and RAM with data retention, makes extended use of low-power energy-modes possible.

### Why?

RAM retention reduces the need for storing data in flash and enables frequent use of the ultra low energy modes EM2 and EM3 with as little as 0.65  $\mu$ A current consumption.

### How?

Low energy and non-volatile flash memory stores program and application data in all energy modes and can easily be reprogrammed in system. Low leakage RAM, with data retention in EM0 to EM3, removes the data restore time penalty, and the DMA ensures fast autonomous transfers with predictable response time.

### 5.1 Introduction

The EFM32WG contains an AMBA AHB Bus system allowing bus masters to access the memory mapped address space. A multilayer AHB bus matrix, using a Round-robin arbitration scheme, connects the master bus interfaces to the AHB slaves (refer to the following figure). The bus matrix allows several AHB slaves to be accessed simultaneously. An AMBA APB interface is used for the peripherals, which are accessed through an AHB-to-APB bridge connected to the AHB bus matrix. The AHB bus masters are:

- Cortex-M4 ICode: Used for instruction fetches from Code memory (0x00000000 0x1FFFFFFF).
- Cortex-M4 DCode: Used for debug and data access to Code memory (0x000000000 0x1FFFFFFF).
- Cortex-M4 System: Used for instruction fetches, data and debug access to system space (0x20000000 0xDFFFFFFF).
- DMA: Can access EBI, SRAM, Flash and peripherals (0x00000000 0xDFFFFFFF).
- USB DMA: Can access EBI, SRAM and Flash (0x80000000 0xDFFFFFFF, 0x000000000 0x3FFFFFFF), and the AHB-peripherals: USB and AES.

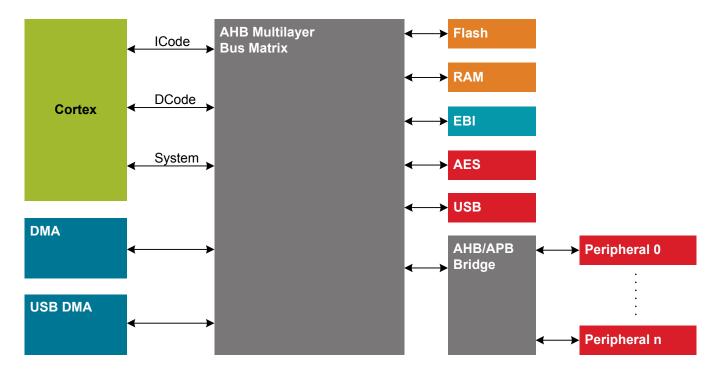

Figure 5.1. EFM32WG Bus System

### 5.2 Functional Description

The memory segments are mapped together with the internal segments of the Cortex-M4 into the system memory map shown by the following figures.

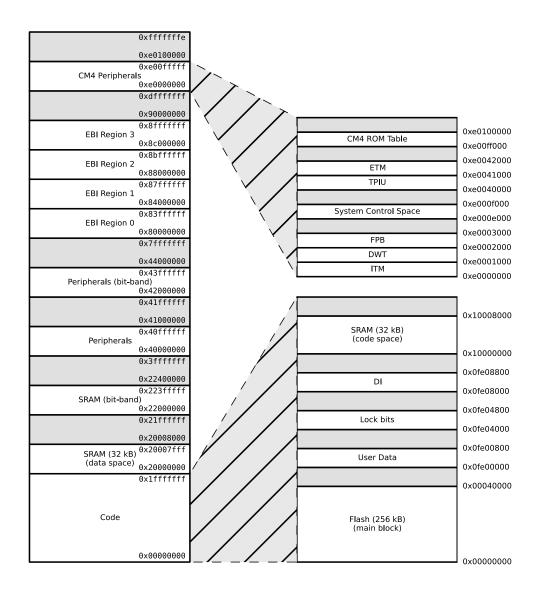

Figure 5.2. System Address Space with Core and Code Space Listing

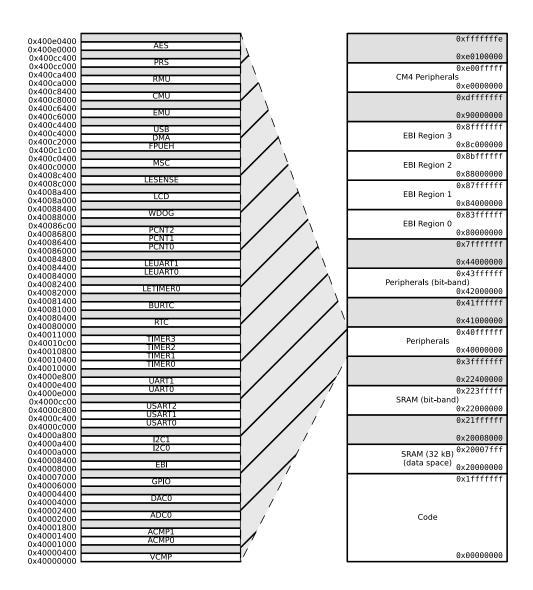

Figure 5.3. System Address Space with Peripheral Listing

The embedded SRAM is located at address 0x20000000 in the memory map of the EFM32WG. When running code located in SRAM starting at this address, the Cortex-M4 uses the System bus to fetch instructions. This results in reduced performance as the Cortex-M4 accesses stack, other data in SRAM and peripherals using the System bus. To be able to run code from SRAM efficiently, the SRAM is also mapped in the code space at address 0x10000000. When running code from this space, the Cortex-M4 fetches instructions through the I/D-Code bus interface, leaving the System bus for data access. The SRAM mapped into the code space can however only be accessed by the CPU, i.e. not the DMA.

## 5.2.1 Bit-Banding

The SRAM bit-band alias and peripheral bit-band alias regions are located at 0x22000000 and 0x42000000 respectively. Read and write operations to these regions are converted into masked single-bit reads and atomic single-bit writes to the embedded SRAM and peripherals of the EFM32WG.

The standard approach to modify a single register or SRAM bit in the aliased regions, requires software to read the value of the byte, half-word or word containing the bit, modify the bit, and then write the byte, half-word or word back to the register or SRAM address. Using bit-banding, this read-modify-write can be done in a single atomic operation. As read-writeback, bit-masking and bit-shift operations are not necessary in software, code size is reduced and execution speed improved.

To set or clear a memory SRAM bit:

 $bit_address = 0x22000000 + (address - 0x20000000) \times 32 + bit \times 4$ 

where address is the address of the 32-bit word containing the bit to modify, and bit is the index of the bit in the 32-bit word.

To modify a bit in the Peripheral area, use the following address:

bit\_address = 0x42000000 + (address - 0x40000000) × 32 + bit × 4

where address and bit are defined as above.

Note that the AHB-peripherals USB and AES does not support bit-banding.

# 5.2.2 Peripherals

The peripherals are mapped into the peripheral memory segment, each with a fixed size address range.

### 5.2.3 Bus Matrix

The Bus Matrix connects the memory segments to the bus masters:

- · Code—CPU instruction or data fetches from the code space
- · System—CPU read and write to the SRAM, EBI and peripherals
- DMA—Access to EBI, SRAM, Flash and peripherals
- · USB DMA—Access to EBI, SRAM and Flash

### 5.2.3.1 Arbitration

The Bus Matrix uses a round-robin arbitration algorithm which enables high throughput and low latency while starvation of simultaneous accesses to the same bus slave are eliminated. Round-robin does not assign a fixed priority to each bus master. The arbiter does not insert any bus wait-states.

#### 5.2.3.2 Access Performance

The Bus Matrix is a multi-layer energy optimized AMBA AHB compliant bus with an internal bandwidth equal to 4 times a single AHB-bus.

The Bus Matrix accepts new transfers initiated by each master in every clock cycle without inserting any wait-states. The slaves, however, may insert wait-states depending on their internal throughput and the clock frequency.

The Cortex-M4, the DMA Controller, and the peripherals run on clocks that can be prescaled separately. When accessing a peripheral which runs on a frequency equal to or faster than the HFCORECLK, the number of wait cycles per access, in addition to master arbitration, is given by:

$$N_{\text{cycles}} = 2 + N_{\text{slave cycles}}$$

where N<sub>slave cycles</sub> is the wait cycles introduced by the slave.

When accessing a peripheral running on a clock slower than the HFCORECLK, wait-cycles are introduced to allow the transfer to complete on the peripheral clock. The number of wait cycles per access, in addition to master arbitration, is given by:

$$N_{\text{cycles}} = (2 + N_{\text{slave cycles}}) \times \frac{f_{\text{HFCORECLK}}}{f_{\text{HFPERCLK}}}$$

where  $N_{\text{slave cycles}}$  is the number of wait cycles introduced by the slave.

For general register access,  $N_{slave cycles} = 1$ .

More details on clocks and prescaling can be found in 11. CMU - Clock Management Unit.

## 5.2.4 Access to Low Energy Peripherals (Asynchronous Registers)

#### 5.2.4.1 Introduction

The Low Energy Peripherals are capable of running when the high frequency oscillator and core system is powered off, i.e. in energy mode EM2 and in some cases also EM3. This enables the peripherals to perform tasks while the system energy consumption is minimal.

The Low Energy Peripherals are:

- · Liquid Crystal Display driver LCD
- Low Energy Timer LETIMER
- Low Energy UART LEUART
- Pulse Counter PCNT
- · Real Time Counter RTC
- · Watchdog WDOG
- Low Energy Sensor Interface LESENSE
- · Backup RTC BURTC

All Low Energy Peripherals are memory mapped, with automatic data synchronization. Because the Low Energy Peripherals are running on clocks asynchronous to the core clock, there are some constraints on how register accesses can be done, as described in the following sections.

### 5.2.4.1.1 Writing

Every Low Energy Peripheral has one or more registers with data that needs to be synchronized into the Low Energy clock domain to maintain data consistency and predictable operation. There are two different synchronization mechanisms on the Wonder Gecko; immediate synchronization, and delayed synchronization. Immediate synchronization is available for the RTC, LETIMER and LESENSE, and results in an immediate update of the target registers. Delayed synchronization is used for the other Low Energy Peripherals, and for these peripherals, a write operation requires 3 positive edges on the clock of the Low Energy Peripheral being accessed. Registers requiring synchronization are marked "Asynchronous" in their description header.

### 5.2.4.1.1.1 Delayed Synchronization

After writing data to a register which value is to be synchronized into the Low Energy Peripheral using delayed synchronization, a corresponding busy flag in the <module\_name>\_SYNCBUSY register (e.g. LEUART\_SYNCBUSY) is set. This flag is set as long as synchronization is in progress and is cleared upon completion.

#### Note:

Subsequent writes to the same register before the corresponding busy flag is cleared is not supported. Write before the busy flag is cleared may result in undefined behavior.

In general, the SYNCBUSY register only needs to be observed if there is a risk of multiple write access to a register (which must be prevented). It is not required to wait until the relevant flag in the SYNCBUSY register is cleared after writing a register. E.g EM2 can be entered immediately after writing a register.

See the following figure for a more detailed overview of the write operation.

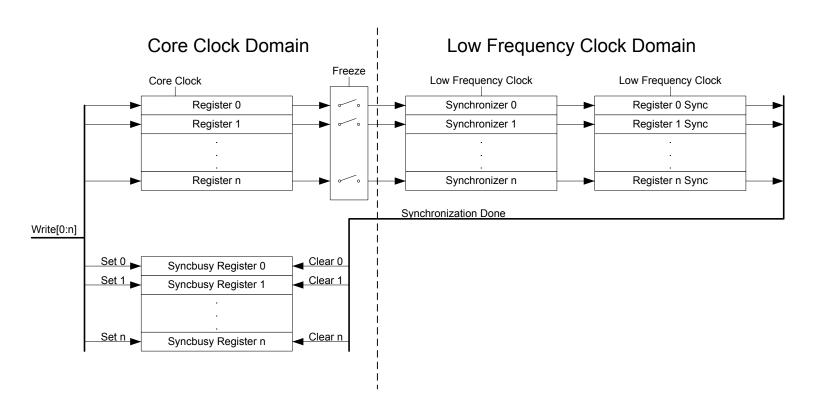

Figure 5.4. Write Operation to Low Energy Peripherals

# 5.2.4.1.1.2 Immediate Synchronization

Contrary to the peripherals with delayed synchronization, data written to peripherals with immediate synchronization, takes effect in the peripheral immediately. They are updated immediately on the peripheral write access. If a write is set up close to a peripheral clock edge, the write is delayed to after the clock edge. This will introduce wait-states on peripheral access. In the worst case, there can be three wait-state cycles of the HFCORECLK\_LE and an additional wait-state equivalent of up to 315 ns.

For peripherals with immediate synchronization, the SYNCBUSY registers are still present and serve two purposes: (1) commands written to a peripheral with immediate synchronization are not executed before the first peripheral clock after the write. During this period, the SYNCBUSY flag in the command register is set, indicating that the command has not yet been executed; (2) to maintain backwards compatibility with the EFM32G series, SYNCBUSY registers are also present for other registers. These are however, always 0, indicating that register writes are always safe.

**Note:** If the application must be compatible with the EFM32G series, all Low Energy Peripherals should be accessed as if they only had delayed synchronization, i.e. using SYNCBUSY.

### 5.2.4.1.2 Reading

When reading from Low Energy Peripherals, the data is synchronized regardless of the originating clock domain. Registers updated/maintained by the Low Energy Peripheral are read directly from the Low Energy clock domain. Registers residing in the core clock domain, are read from the core clock domain. See the following figure for a more detailed overview of the read operation.

**Note:** Writing a register and then immediately reading back the value of the register may give the impression that the write operation is complete. This is not necessarily the case. Please refer to the SYNCBUSY register for correct status of the write operation to the Low Energy Peripheral.

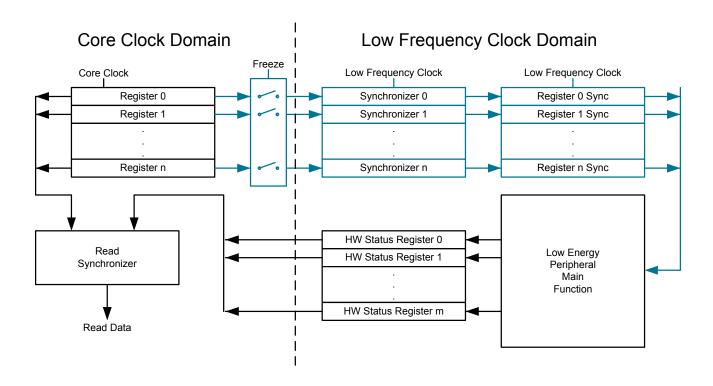

Figure 5.5. Read Operation from Low Energy Peripherals

### 5.2.4.2 FREEZE Register

For Low Energy Peripherals with delayed synchronization there is a <module\_name>\_FREEZE register (e.g. RTC\_FREEZE), containing a bit named REGFREEZE. If precise control of the synchronization process is required, this bit may be utilized. When REGFREEZE is set, the synchronization process is halted, allowing the software to write multiple Low Energy registers before starting the synchronization process, thus providing precise control of the module update process. The synchronization process is started by clearing the REGFREEZE bit.

Note: The FREEZE register is also present on peripherals with immediate synchronization, but has no effect.

### 5.2.5 Flash

The Flash retains data in any state and typically stores the application code, special user data and security information. The Flash memory is typically programmed through the debug interface, but can also be erased and written to from software.

- · Up to 256 kB of memory
- · Page size of 2048 bytes (minimum erase unit)
- Minimum 20,000 erase cycles
- · More than 10 years data retention at 85 °C
- · Lock-bits for memory protection
- · Data retention in any state

# 5.2.6 SRAM

The primary task of the SRAM memory is to store application data. Additionally, it is possible to execute instructions from SRAM, and the DMA may used to transfer data between the SRAM, Flash and peripherals.

- · Up to 32 kB memory
- · Bit-band access support
- Data retention of the entire memory in EM0 to EM3

# 5.2.7 Device Information (DI) Page

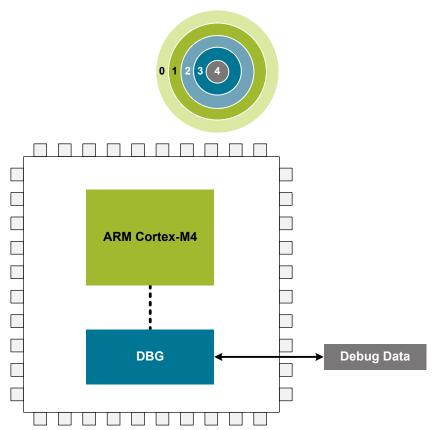

The DI page contains calibration values, a unique identification number and other useful data. See the table below for a complete overview.

**Table 5.4. Device Information Page Contents** 

DI Address	Register	Description										
0x0FE08020	CMU_LFRCOCTRL	Register reset value.

0x0FE081BE	ADC0_TEMP_0_READ_1V25	[15:4] Temperature reading at 1V25 reference, [3:0] Reserved.										
0x0FE081C8	DAC0_CAL_1V25	22:16]: Gain for 1V25 reference, [13:8]: Channel 1 offset for 1V25 reference, [5:0]: Channel 0 offset for 1V25 reference.										
0x0FE081CC	DAC0_CAL_2V5	22:16]: Gain for 2V5 reference, [13:8]: Channel 1 offset for 2V5 reference, [5:0]: Channel 0 offset for 2V5 reference.										
0x0FE081D0	DAC0_CAL_VDD	[22:16]: Reserved (gain for this reference cannot be calibrated), [13:8]: Channel 1 offset for VDD reference, [5:0]: Channel 0 offset for VDD reference.										
0x0FE081D4	AUXHFRCO_CALIB_BAND_1	[7:0]: Tuning for the 1.2 MHZ AUXHFRCO band.										

DI Address	Register	Description
0x0FE081D5	AUXHFRCO_CALIB_BAND_7	[7:0]: Tuning for the 6.6 MHZ AUXHFRCO band.
0x0FE081D6	AUXHFRCO_CALIB_BAND_11	7:0]: Tuning for the 11 MHZ AUXHFRCO band.
0x0FE081D7	AUXHFRCO_CALIB_BAND_14	[7:0]: Tuning for the 14 MHZ AUXHFRCO band.
0x0FE081D8	AUXHFRCO_CALIB_BAND_21	[7:0]: Tuning for the 21 MHZ AUXHFRCO band.
0x0FE081D9	AUXHFRCO_CALIB_BAND_28	[7:0]: Tuning for the 28 MHZ AUXHFRCO band.
0x0FE081DC	HFRCO_CALIB_BAND_1	[7:0]: Tuning for the 1.2 MHZ HFRCO band.
0x0FE081DD	HFRCO_CALIB_BAND_7	[7:0]: Tuning for the 6.6 MHZ HFRCO band.
0x0FE081DE	HFRCO_CALIB_BAND_11	[7:0]: Tuning for the 11 MHZ HFRCO band.
0x0FE081DF	HFRCO_CALIB_BAND_14	[7:0]: Tuning for the 14 MHZ HFRCO band.
0x0FE081E0	HFRCO_CALIB_BAND_21	[7:0]: Tuning for the 21 MHZ HFRCO band.
0x0FE081E1	HFRCO_CALIB_BAND_28	[7:0]: Tuning for the 28 MHZ HFRCO band.
0x0FE081E7	MEM_INFO_PAGE_SIZE	[7:0] Flash page size in bytes coded as 2 ^ ((MEM_IN-FO_PAGE_SIZE + 10) & 0xFF). le. the value 0xFF = 512 bytes.
0x0FE081F0	UNIQUE_0	[31:0] Unique number.
0x0FE081F4	UNIQUE_1	[63:32] Unique number.
0x0FE081F8	MEM_INFO_FLASH	[15:0]: Flash size, kbyte count as unsigned integer (eg. 128).
0x0FE081FA	MEM_INFO_RAM	[15:0]: Ram size, kbyte count as unsigned integer (eg. 16).
0x0FE081FC	PART_NUMBER	[15:0]: EFM32 part number as unsigned integer (eg. 230).
0x0FE081FE	PART_FAMILY	[7:0]: EFM32 part family number (Gecko = 71, Giant Gecko = 72, Tiny Gecko = 73, Leopard Gecko=74, Wonder Gecko=75).
0x0FE081FF	PROD_REV	[7:0]: EFM32 Production ID.

# 6. DBG - Debug Interface

#### **Quick Facts**

### What?

The DBG (Debug Interface) is used to program and debug EFM32WG devices.

### Why?

The Debug Interface makes it easy to reprogram and update the system in the field, and allows debugging with minimal I/O pin usage.

#### How?

The Cortex-M4 supports advanced debugging features. EFM32WG devices only use two port pins for debugging or programming. The internal and external state of the system can be examined with debug extensions supporting instruction or data access break- and watch points.

# 6.1 Introduction

The EFM32WG devices include hardware debug support through a 2-pin serial-wire debug (SWD) interface and an Embedded Trace Module (ETM) for data/instruction tracing. In addition, there is also a Serial Wire Viewer pin which can be used to output profiling information, data trace, and software generated messages.

For more technical information about the debug interface the reader is referred to:

- · ARM Cortex-M4 Technical Reference Manual
- · ARM CoreSight Components Technical Reference Manual
- · ARM Debug Interface v5 Architecture Specification

## 6.2 Features

- · Flash Patch and Breakpoint (FPB) unit
  - · Implement breakpoints and code patches
- · Data Watch point and Trace (DWT) unit
  - Implement watch points, trigger resources and system profiling
- · Instrumentation Trace Macrocell (ITM)
  - · Application-driven trace source that supports printf style debugging
- Embedded Trace Macrocell v3.5 (ETM)
  - · Real time instruction and data trace information of the processor

### 6.3 Functional Description

There are three debug pins and four trace pins available on the device. Operation of these pins are described in the following section.

### 6.3.1 Debug Pins

The following pins are the debug connections for the device:

- · Serial Wire Clock input (SWCLK): This pin is enabled after reset and has a built-in pull down.
- · Serial Wire Data Input/Output (SWDIO): This pin is enabled after reset and has a built-in pull-up.
- · Serial Wire Viewer (SWV): This pin is disabled after reset.

The debug pins can be enabled and disabled through GPIO\_ROUTE, see 32.3.4.1 Serial Wire Debug Port Connection. Please remeberer that upon disabling, debug contact with the device is lost. Also note that, because the debug pins have pull-down and pull-up enabled by default, leaving them enabled might increase the current consumption with up to 200  $\mu$ A if left connected to supply or ground.

### 6.3.2 Embedded Trace Macrocell v3.5 (ETM)

The ETM makes it possible to trace both instruction and data from the processor in real time. The trace can be controlled through a set of triggering and filtering resources. The resources include 4 address comparators, 2 data value comparators, 2 counters, a context ID comparator and a sequencer. Before enabling the ETM, the AUXHFRCO clock needs to be enabled by setting AUXHFRCOEN in CMU\_OSCENCMD. The trace can be exported through a set of trace pins, which include:

- Trace Clock (TCLK): Functions as a sample clock for the trace. This pin is disabled after reset.
- Trace Data 0 Trace Data 3 (TD0-TD3): The data pins provide the compressed trace stream. These pins are disabled after reset.

For information on how to configure the ETM, see the ARM Embedded Trace Macrocell Architecture Specification. The Trace Clock and Trace Data pins can be enabled through the GPIO. For more information on how to enable the ETM Trace pins, the reader is referred to 32.3.4.2 ETM Trace Ports.

### 6.3.3 Debug and EM2/EM3

Leaving the debugger connected when issuing a WFI or WFE to enter EM2 or EM3 will make the system enter a special EM2. This mode differs from regular EM2 and EM3 in that the high frequency clocks are still enabled, and certain core functionality is still powered in order to maintain debug-functionality. Because of this, the current consumption in this mode is closer to EM1 and it is therefore important to disconnect the debugger before doing current consumption measurements.

### 6.3.4 Debug Lock and Device Erase

The debug access to the Cortex-M4 is locked by clearing the Debug Lock Word (DLW) and resetting the device, see 7.3.2 Lock Bits (LB) Page Description.

When debug access is locked, the debug interface remains accessible but the connection to the Cortex- M4 core and the whole bussystem is blocked as shown in Figure 6.2 Device Unlock on page 56. This mechanism is controlled by the Authentication Access Port (AAP) as illustrated by Figure 6.1 AAP - Authentication Access Port on page 56. The AAP is only accessible from a debugger and not from the core.

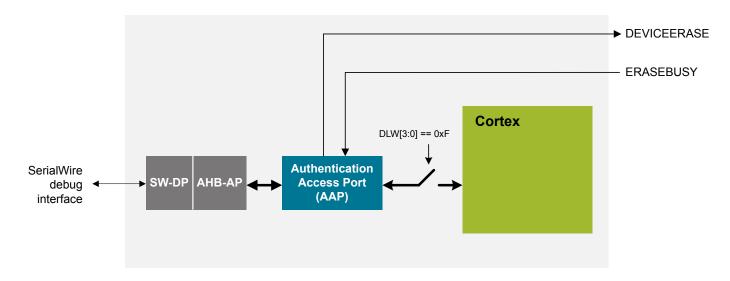

Figure 6.1. AAP - Authentication Access Port

The debugger can access the AAP-registers, and only these registers just after reset, for the time of the AAP-window outlined in the following figure. If the device is locked, access to the core and bus-system is blocked even after code execution starts, and the debugger can only access the AAP-registers. If the device is not locked, the AAP is no longer accessible after code execution starts, and the debugger can access the core and bus-system normally. The AAP window can be extended by issuing the bit pattern on SWDIO/SWCLK as shown in Figure 6.3 AAP Expansion on page 576.3.4 Debug Lock and Device Erase. This pattern should be applied just before reset is deasserted, and will give the debugger more time to access the AAP.

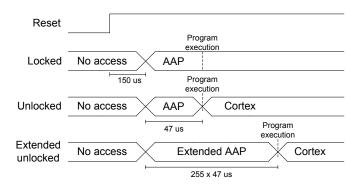

Figure 6.2. Device Unlock

If the device is locked, it can be unlocked by writing a valid key to the AAP\_CMDKEY register and then setting the DEVICEERASE bit of the AAP\_CMD register via the debug interface. The commands are not executed before AAP\_CMDKEY is invalidated, so this register should be cleared to to start the erase operation. This operation erases the main block of flash, all lock bits are reset and debug access through the AHB-AP is enabled. The operation takes 125 ms to complete. Note that the SRAM contents will also be deleted during a device erase, while the UD-page is not erased.

Even if the device is not locked, the device can be erased through the AAP, using the above procedure during the AAP window. This can be useful if the device has been programmed with code that, e.g., disables the debug interface pins on start-up, or does something else that prevents communication with a debugger.

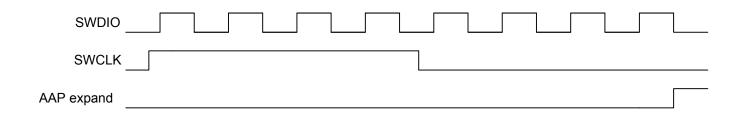

Figure 6.3. AAP Expansion

If the device is locked, the debugger may read the status from the AAP\_STATUS register. When the ERASEBUSY bit is set low after DEVICEERASE of the AAP\_CMD register is set, the debugger may set the SYSRESETREQ bit in the AAP\_CMD register. After reset, the debugger may resume a normal debug session through the AHB-AP. If the device is not locked, the device erase starts when the AAP window closes, so it is not possible to poll the status.

# 6.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	AAP_CMD	W1	Command Register
0x004	AAP_CMDKEY	W1	Command Key Register
0x008	AAP_STATUS	R	Status Register
0x0FC	AAP_IDR	R	AAP Identification Register

# 6.5 Register Description

# 6.5.1 AAP\_CMD - Command Register

# 7. MSC - Memory System Controller

#### **Quick Facts**

### What?

The user can perform Flash memory read, read configuration and write operations through the Memory System Controller (MSC).

### Why?

The MSC allows the application code, user data and flash lock bits to be stored in non-volatile Flash memory. Certain memory system functions, such as program memory wait-states and bus faults are also configured from the MSC peripheral register interface, giving the developer the ability to dynamically customize the memory system performance, security level, energy consumption and error handling capabilities to the requirements at hand.

### How?

The MSC integrates a low-energy Flash IP with a charge pump, enabling minimum energy consumption while eliminating the need for external programming voltage to erase the memory. An easy to use write and erase interface is supported by an internal, fixed-frequency oscillator and autonomous flash timing and control reduces software complexity while not using other timer resources.

Application code may dynamically scale between high energy optimization and high code execution performance through advanced read modes.

A highly efficient low energy instruction cache reduces the number of flash reads significantly, thus saving energy. Performance is also improved when wait states are used, since many of the wait-states are eliminated. Built-in performance counters can be used to measure the efficiency of the instruction cache.

#### 7.1 Introduction

The Memory System Controller (MSC) is the program memory unit of the EFM32WG microcontroller. The flash memory is readable and writable from both the Cortex-M4 and DMA. The flash memory is divided into two blocks; the main block and the information block. Program code is normally written to the main block. Additionally, the information block is available for special user data and flash lock bits. There is also a read-only page in the information block containing system and device calibration data. Read and write operations are supported in the energy modes EM0 and EM1.

#### 7.2 Features

- · AHB read interface
  - Scalable access performance to optimize the Cortex-M4 code interface
    - Zero wait-state access up to 16 MHz and one wait-state for up to 32 MHz and two wait-states for up to 48 MHz
    - · Advanced energy optimization functionality
      - · Conditional branch target prefetch suppression
      - · Cortex-M4 disfolding of if-then (IT) blocks
      - · Instruction Cache
  - DMA read support in EM0 and EM1
- · Command and status interface
  - · Flash write and erase
    - · Accessible from Cortex-M4 in EM0
    - DMA write support in EM0 and EM1
  - · Core clock independent Flash timing
    - · Internal oscillator and internal timers for precise and autonomous Flash timing
      - · General purpose timers are not occupied during Flash erase and write operations
  - · Configurable interrupt erase abort
    - · Improved interrupt predictability
  - · Memory and bus fault control
- · Security features
  - · Lockable debug access
  - · Page lock bits
  - · SW Mass erase Lock bits
  - · User data lock bits
- · End-of-write and end-of-erase interrupts

# 7.3 Functional Description

The size of the main block is device dependent. The largest size available is 256 kB (128 pages). The information block has 2048 bytes available for user data. The information block also contains chip configuration data located in a reserved area. The main block is mapped to address 0x000000000 and the information block is mapped to address 0x0FE00000. The table below outlines how the Flash is mapped in the memory space. All Flash memory is organized into 2048 byte pages.

Block	Page	Base address	Write/Erase by	Software readable	Purpose/Name	Size
Main <sup>1</sup>	0 0x0000000		Software, debug	Yes	User code and data	64 kB – 256 kB
	_		Software, debug	Yes		
	127	0x0003F800	Software, debug	Yes		
Reserved	_	0x00040000	_	_	Reserved for flash expansion	~24 MB
Information	0	0x0FE00000	Software, debug	Yes	User Data (UD)	2 kB
	_	0x0FE00800	_	_	Reserved	_
	1	0x0FE04000	Write: Software, debug	Yes	Lock Bits (LB)	2 kB
			Erase: Debug only			
	_	0x0FE04800	_	_	Reserved	_
	2	0x0FE08000	_	Yes	Device Information (DI)	2 kB
	_	0x0FE08800	_	_	Reserved	_
Reserved	_	0x0FE10000	_	_	Reserved for flash expansion	Rest of code space

## Note:

1. Block/page erased by a device erase.

### 7.3.1 User Data (UD) Page Description

This is the user data page in the information block. The page can be erased and written by software. The page is erased by the ERA-SEPAGE command of the MSC\_WRITECMD register. Note that the page is not erased by a device erase operation. The device erase operation is described in 6.3.4 Debug Lock and Device Erase.

### 7.3.2 Lock Bits (LB) Page Description

This page contains the following information:

- Debug Lock Word (DLW)
- User data page Lock Word (ULW)
- · Mass erase Lock Word (MLW)
- Main block Page Lock Words (PLWs)

The words in this page are organized as shown in the table below:

Table 7.1. Lock Bits Page Structure

Word Index	Description
127	DLW
126	ULW
125	MLW
N	PLW[N]
1	PLW[1]
0	PLW[0]

Word 127 is the debug lock word (DLW). The four LSBs of this word are the debug lock bits. If these bits are 0xF, then debug access is enabled. If the bits are not 0xF, then debug access to the core is locked. See 6.3.4 Debug Lock and Device Erase for details on how to unlock the debug access.

Word 126 is the user page lock word (ULW). Bit 0 of this word is the User Data Page lock bit. Bit 1 in this word locks the Lock Bits Page.

Word 125 is the mass erase lock word (MLW). Bit 0 locks the entire flash. The mass erase lock bits will not have any effect on device erases initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in 6.3.4 Debug Lock and Device Erase.

There are 32 page lock bits per page lock word (PLW). Bit 0 refers to the first page and bit 31 refers to the last page within a PLW. Thus, PLW[0] contains lock bits for page 0-31 in the main block. Similarly, PLW[1] contains lock bits for page 32-63 and so on. A page is locked when the bit is 0. A locked page cannot be erased or written.

The lock bits can be reset by a device erase operation initiated from the Authentication Access Port (AAP) registers. The AAP is described in more detail in 6.3.4 Debug Lock and Device Erase. Note that the AAP is only accessible from the debug interface, and cannot be accessed from the Cortex-M4 core.

## 7.3.3 Device Information (DI) Page

This read-only page holds the calibration data for the oscillator and other analog peripherals from the production test as well as a unique device ID. The page is further described in 5.2.5 Flash.

### 7.3.4 Post-Reset Behavior

Calibration values are automatically written to registers by the MSC before application code startup. The values are also available to read from the DI page for later reference by software. Other information such as the device ID and production date is also stored in the DI page and is readable from software.

# 7.3.4.1 One Wait-State Access

After reset, the HFCORECLK is normally 14 MHz from the HFRCO and the MODE field of the MSC\_READCTRL register is set to WS1 (one wait-state). The reset value must be WS1 as an uncalibrated HFRCO may produce a frequency higher than 16 MHz. Software must not select a zero wait-state mode unless the clock is guaranteed to be 16 MHz or below, otherwise the resulting behavior is undefined. If a HFCORECLK frequency above 16 MHz is to be set by software, the MODE field of the MSC\_READCTRL register must be set to WS1 or WS1SCBTP before the core clock is switched to the higher frequency clock source.

When changing to a lower frequency, the MODE field of the MSC\_READCTRL register can be set to WS0 or WS0SCBTP, but only after the frequency transition is completed. If the HFRCO is used, wait until the oscillator is stable on the new frequency. Otherwise, the behavior is unpredictable.

To run at a frequency higher than 32 MHz, WS2 or WS2SCBTP must be selected to insert two wait-states for every flash access.

#### 7.3.4.2 Zero Wait-State Access

At 16 MHz and below, read operations from flash may be performed without any wait-states. Zero wait-state access greatly improves code execution performance at frequencies from 16 MHz and below. By default, the Cortex-M4 uses speculative prefetching and If-Then block folding to maximize code execution performance at the cost of additional flash accesses and energy consumption.

### 7.3.4.3 Operation Above 32 MHz

To run at frequencies higher than 32 MHz, MODE in MSC READCTRL must be set to WS2 or WS2SCBTP.

### 7.3.4.4 Suppressed Conditional Branch Target Prefetch

MSC offers a special instruction fetch mode which optimizes energy consumption by cancelling Cortex- M4 conditional branch target prefetches. Normally, the Cortex-M4 core prefetches both the next sequential instruction and the instruction at the branch target address when a conditional branch instruction reaches the pipeline decode stage. This prefetch scheme improves performance while one extra instruction is fetched from memory at each conditional branch, regardless of whether the branch is taken or not. To optimize for low energy, the MSC can be configured to cancel these speculative branch target prefetches. With this configuration, energy consumption is more optimal, as the branch target instruction fetch is delayed until the branch condition is evaluated.

The performance penalty with this mode enabled is source code dependent, but is normally less than 1% for core frequencies from 16 MHz and below. To enable the mode at frequencies from 16 MHz and below write WS0SCBTP to the MODE field of the MSC\_READCTRL register. For frequencies above 16 MHz, use the WS1SCBTP mode, and for frequencies above 32 MHz, use the WS2SCBTP mode. An increased performance penalty per clock cycle must be expected compared to WS0SCBTP mode. The performance penalty in WS1SCBTP/WS2SCBTP mode depends greatly on the density and organization of conditional branch instructions in the code.

## 7.3.4.5 Cortex-M4 If-Then Block Folding

The Cortex-M4 offers a mechanism known as if-then block folding. This is a form of speculative prefetching where small if-then blocks are collapsed in the prefetch buffer if the condition evaluates to false. The instructions in the block then appear to execute in zero cycles. With this scheme, performance is optimized at the cost of higher energy consumption as the processor fetches more instructions from memory than it actually executes. To disable the mode, write a 1 to the DISFOLD bit in the NVIC Auxiliary Control Register; see the Cortex-M4 Technical Reference Manual for details. Normally, it is expected that this feature is most efficient at core frequencies above 16 MHz. Folding is enabled by default.

### 7.3.4.6 Instruction Cache

The MSC includes an instruction cache. The instruction cache for the internal flash memory is enabled by default, but can be disabled by setting IFCDIS in MSC\_READCTRL. When enabled, the instruction cache typically reduces the number of flash reads significantly, thus saving energy. In most cases a cache hit-rate of more than 70 % is achievable. When a 32-bit instruction fetch hits in the cache the data is returned to the processor in one clock cycle. Thus, performance is also improved when wait-states are used (i.e. running at frequencies above 16 MHz).

The instruction cache is connected directly to the Cortex-M4 and functions as a memory access filter between the processor and the memory system, as illustrated in the following figure. The cache consists of an access filter, lookup logic, a 128x32 SRAM (512 bytes) and two performance counters. The access filter checks that the address for the access is of an instruction in the code space (instructions in RAM outside the code space are not cached). If the address matches, the cache lookup logic and SRAM is enabled. Otherwise, the cache is bypassed and the access is forwarded to the memory system. The cache is then updated when the memory access completes. The access filter also disables cache updates for interrupt context accesses if caching in interrupt context is disabled. The performance counters, when enabled, keep track of the number of cache hits and misses. The cache consists of 16 8-word cachelines organized as 4 sets with 4 ways. The cachelines are filled up continuously one word at a time as the individual words are requested by the processor. Thus, not all words of a cacheline might be valid at a given time.

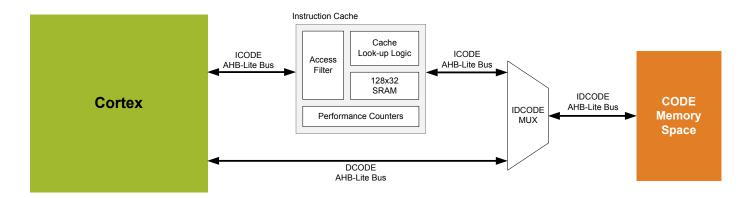

Figure 7.1. Instruction Cache

By default, the instruction cache is automatically invalidated when the contents of the flash is changed (i.e. written or erased). In many cases, however, the application only makes changes to data in the flash, not code. In this case, the automatic invalidate feature can be disabled by setting AIDIS in MSC\_READCTRL. The cache can (independent of the AIDIS setting) be manually invalidated by writing 1 to INVCACHE in MSC\_CMD.

In general it is highly recommended to keep the cache enabled all the time. However, for some sections of code with very low cache hitrate more energy-efficient execution can be achieved by disabling the cache temporarily. To measure the hit-rate of a code-section, the built-in performance counters can be used. Before the section, start the performance counters by writing 1 to STARTPC in MSC\_CMD. This starts the performance counters, counting from 0. At the end of the section, stop the performance counters by writing 1 to STOPPC in MSC\_CMD. The number of cache hits and cache misses for that section can then be read from MSC\_CACHEHITS and MSC\_CACHEMISSES respectively. The total number of 32-bit instruction fetches will be MSC\_CACHEHITS + MSC\_CACHEMISSES. Thus, the cache hit-ratio can be calculated as MSC\_CACHEHITS / (MSC\_CACHEHITS + MSC\_CACHEMISSES). When MSC\_CACHEHITS overflows the CHOF interrupt flag is set. When MSC\_CACHEMISSES overflows the CMOF interrupt flag is set. These flags must be cleared explicitly by software. The range of the performance counters can thus be extended by increasing a counter in the MSC interrupt routine. The performance counters only count when a cache lookup is performed. If the lookup fails, MSC\_CACHEMISSES is increased. If the lookup is successful, MSC\_CACHEHITS is increased. For example, a cache lookup is not performed if the cache is disabled or the code is executed from RAM outside the code space. When caching of vector fetches and instructions in interrupt routines is disabled (ICCDIS in MSC\_READCTRL is set), the performance counters do not count when these types of fetches occur (i.e. while in interrupt context).

By default, interrupt vector fetches and instructions in interrupt routines are also cached. Some applications may get better cache utilization by not caching instructions in interrupt context. This is done by setting ICCDIS in MSC\_READCTRL. You should only set this bit based on the results from a cache hit ratio measurement. In general, it is recommended to keep the ICCDIS bit cleared. Note that look-ups in the cache are still performed, regardless of the ICCDIS setting - but instructions are not cached when cache misses occur inside the interrupt routine. So, for example, if a cached function is called from the interrupt routine, the instructions for that function will be taken from the cache.

The cache content is not retained in EM2, EM3 and EM4. The cache is therefore invalidated regardless of the setting of AIDIS in MSC\_READCTRL when entering these energy modes. Applications that switch frequently between EM0 and EM2/3 and execute the very same non-looping code almost every time will most likely benefit from putting this code in RAM. The interrupt vectors can also be put in RAM to reduce current consumption even further.

The cache also supports caching of instruction fetches from the external bus interface (EBI) when accessing the EBI through code space. By default, this is enabled, but it can be disabled by setting EBICDIS in MSC READCTRL.

### 7.3.5 Erase and Write Operations

The AUXHFRCO is used for timing during flash write and erase operations. To achieve correct timing, the MSC\_TIMEBASE register has to be configured according to the settings in CMU\_AUXHFRCOCTRL. BASE in MSC\_TIMEBASE defines how many AUXCLK cycles - 1 there is in 1 us or 5 us, depending on the configuration of PERIOD. To ensure that timing of flash write and erase operations is within the specification of the flash, the value written to BASE should give at least a 10% margin with respect to the period, i.e. for the 1 us PERIOD, the number of cycles should at least span 1.1 us, and for the 5 us period they should span at least 5.5 us. For the 1 MHz band, PERIOD in MSC\_TIMEBASE should be set to 5US, while it should be set to 1US for all other AUXHFRCO bands.

Both page erase and write operations require that the address is written into the MSC\_ADDRB register. For erase operations, the address may be any within the page to be erased. Load the address by writing 1 to the LADDRIM bit in the MSC\_WRITECMD register. The LADDRIM bit only has to be written once when loading the first address. After each word is written the internal address register ADDR will be incremented automatically by 4. The INVADDR bit of the MSC\_STATUS register is set if the loaded address is outside the flash and the LOCKED bit of the MSC\_STATUS register is set if the page addressed is locked. Any attempts to command erase of or write to the page are ignored if INVADDR or the LOCKED bits of the MSC\_STATUS register are set. To abort an ongoing erase, set the ERASEABORT bit in the MSC\_WRITECMD register.

When a word is written to the MSC\_WDATA register, the WDATAREADY bit of the MSC\_STATUS register is cleared. When this status bit is set, software or DMA may write the next word.

A single word write is commanded by setting the WRITEONCE bit of the MSC\_WRITECMD register. The operation is complete when the BUSY bit of the MSC\_STATUS register is cleared and control of the flash is handed back to the AHB interface, allowing application code to resume execution.

For a DMA write the software must write the first word to the MSC\_WDATA register and then set the WRITETRIG bit of the MSC\_WRITECMD register. DMA triggers when the WDATAREADY bit of the MSC\_STATUS register is set.

It is possible to write words twice between each erase by keeping at 1 the bits that are not to be changed. Let us take as an example writing two 16 bit values, 0xAAAA and 0x5555. To safely write them in the same flash word this method can be used:

- Write 0xFFFFAAAA (word in flash becomes 0xFFFFAAAA)
- Write 0x5555FFFF (word in flash becomes 0x5555AAAA)

**Note:** During a write or erase, flash read accesses will be stalled, effectively halting code execution from flash. Code execution continues upon write/erase completion. Code residing in RAM may be executed during a write/erase operation.

Note: The MSC WDATA and MSC ADDRB registers are not retained when entering EM2 or lower energy modes.

#### 7.3.5.1 Mass Erase

A mass erase can be initiated from software using ERASEMAIN0 in MSC\_WRITECMD. This command will start a mass erase of the entire flash. Prior to initiating a mass erase, MSC\_MASSLOCK must be unlocked by writing 0x631A to it. After a mass erase has been started, this register can be locked again to prevent runaway code from accidentally triggering a mass erase.

The regular flash page lock bits will not prevent a mass erase. To prevent software from initiating mass erases, use the mass erase lock bits in the mass erase lock word (MLW).

5 ICCDIS 0 RW Interrupt Context Cache Disable

RW

Set this bit to automatically disable caching of vector fetches and instruction fetches in interrupt context. Cache lookup will still be performed in interrupt context. When set, the performance counters will not count when these types of fetches occur.

**External Bus Interface Cache Disable** 

**RAM Cache Enable** 

4 AIDIS 0 RW Automatic Invalidate Disable

When this bit is set the cache is not automatically invalidated when a write or page erase is performed.

IFCDIS 0 RW Internal Flash Cache Disable

MODE 0x1 RW Read Mode

Disable instruction cache for internal flash memory.

0

Enable instruction caching for RAM in code-space.

Disable instruction cache for external bus interface.

If software wants to set a core clock frequency above 16 MHz, this register must be set to WS1 or WS1SCBTP before the core clock is switched to the higher frequency. When changing to a lower frequency, this register can be set to WS0 or WS0SCBTP after the frequency transition has been completed. After reset, the core clock is 14 MHz from the HFRCO but the MODE field of MSC\_READCTRL register is set to WS1. This is because the HFRCO may produce a frequency above 16 MHz before it is calibrated. If the HFRCO is used as clock source, wait until the oscillator is stable on the new frequency to avoid unpredictable behavior.

7

6

3

2:0

**RAMCEN** 

**EBICDIS** 

3it	Name	Reset	Access	Description
	Value	Mode		Description
	0	WS0		Zero wait-states inserted in fetch or read transfers.
	1	WS1		One wait-state inserted for each fetch or read transfer. This mode is required for a core frequency above 16 MHz.
	2	WS0SCBTP		Zero wait-states inserted with the Suppressed Conditional Branch Target Prefetch (SCBTP) function enabled. SCBTP saves energy by delaying the Cortex' conditional branch target prefetches until the conditional branch instruction is in the execute stage. When the instruction reaches this stage, the evaluation of the branch condition is completed and the core does not perform a speculative prefetch of both the branch target address and the next sequential address. With the SCBTP function enabled, one instruction fetch is saved for each branch not taken, with a negligible performance penalty.
	3	WS1SCBTP		One wait-state access with SCBTP enabled.
	4	WS2		Two wait-states inserted for each fetch or read transfer. This mode is required for a core frequency above 32 MHz.
	5	WS2SCBTP		Two wait-state access with SCBTP enabled.

## 8. DMA - DMA Controller

#### **Quick Facts**

#### What?

The DMA controller can move data without CPU intervention, effectively reducing the energy consumption for a data transfer.

## Why?

The DMA can perform data transfers more energy efficiently than the CPU and allows autonomous operation in low energy modes. The LEUART can for instance provide full UART communication in EM2, consuming only a few µA by using the DMA to move data between the LEUART and RAM.

#### How?

The DMA controller has multiple highly configurable, prioritized DMA channels. Advanced transfer modes such as ping-pong and scatter-gather make it possible to tailor the controller to the specific needs of an application.

#### 8.1 Introduction

The Direct Memory Access (DMA) controller performs memory operations independently of the CPU. This has the benefit of reducing the energy consumption and the workload of the CPU, and enables the system to stay in low energy modes for example when moving data from the USART to RAM or from the External Bus Interface (EBI) to the DAC. The DMA controller uses the PL230 µDMA controller licensed from ARM.

Note: ARM PL230 homepage [ http://infocenter.arm.com/help/index.jsp?topic=/com.arm.doc.ddi0417a/index.html ].

Each of the PL230s channels on the EFM32 can be connected to any of the EFM32 peripherals.

#### 8.2 Features

- · The DMA controller is accessible as a memory mapped peripheral
- · Possible data transfers include
  - · RAM/EBI/Flash to peripheral
  - · RAM/EBI to Flash
  - Peripheral to RAM/EBI
  - · RAM/EBI/Flash to RAM/EBI
- · The DMA controller has 12 independent channels
- · Each channel has one (primary) or two (primary and alternate) descriptors
- · The configuration for each channel includes
  - · Transfer mode
  - Priority
  - · Word-count
  - Word-size (8, 16, 32 bit)
- · The transfer modes include
  - Basic (using the primary or alternate DMA descriptor)
  - Ping-pong (switching between the primary or alternate DMA descriptors, for continuous data flow to/from peripherals)
  - · Scatter-gather (using the primary descriptor to configure the alternate descriptor)
- · Each channel has a programmable transfer length
- · Channels 0 and 1 support looped transfers
- · Channel 0 supports 2D copy
- · A DMA channel can be triggered by any of several sources:
  - · Communication modules (USART, UART, LEUART)
  - · Timers (TIMER)
  - Analog modules (DAC, ACMP, ADC)
  - External Bus Interface (EBI)
  - · Software
- Programmable mapping between channel number and peripherals any DMA channel can be triggered by any of the available sources
- · Interrupts upon transfer completion
- Data transfer to/from LEUART in EM2 is supported by the DMA, providing extremely low energy consumption while performing UART communications

## 8.3 Block Diagram

An overview of the DMA and the modules it interacts with is shown in the following figure.

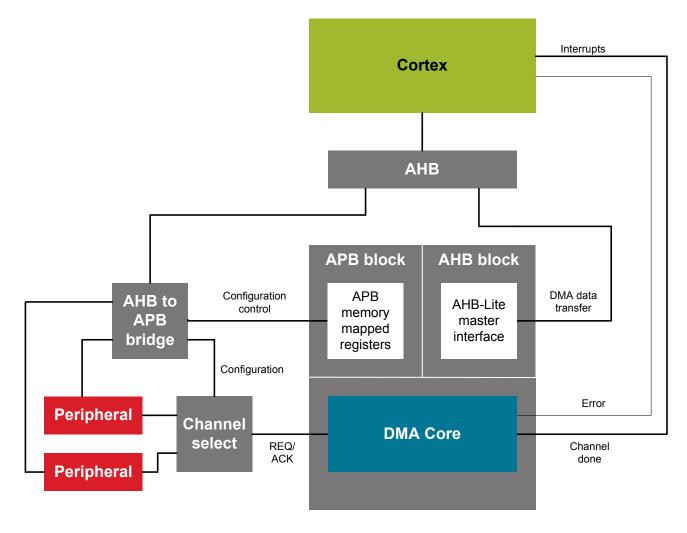

Figure 8.1. DMA Block Diagram

The DMA Controller consists of four main parts:

- · An APB block allowing software to configure the DMA controller
- · An AHB block allowing the DMA to read and write the DMA descriptors and the source and destination data for the DMA transfers
- · A DMA control block controlling the operation of the DMA, including request/acknowledge signals for the connected peripherals
- · A channel select block routing the right peripheral request to each DMA channel

#### 8.4 Functional Description

The DMA Controller is highly flexible. It is capable of transferring data between peripherals and memory without involvement from the processor core. This can be used to increase system performance by off-loading the processor from copying large amounts of data or avoiding frequent interrupts to service peripherals needing more data or having available data. It can also be used to reduce the system energy consumption by making the DMA work autonomously with the LEUART for data transfer in EM2 without having to wake up the processor core from sleep.

The DMA Controller contains 12 independent channels. Each of these channels can be connected to any of the available peripheral trigger sources by writing to the configuration registers, see 8.4.1 Channel Select Configuration. In addition, each channel can be triggered by software (for large memory transfers or for debugging purposes).

What the DMA Controller should do (when one of its channels is triggered) is configured through channel descriptors residing in system memory. Before enabling a channel, the software must therefore take care to write this configuration to memory. When a channel is triggered, the DMA Controller will first read the channel descriptor from system memory, and then it will proceed to perform the memory transfers as specified by the descriptor. The descriptor contains the memory address to read from, the memory address to write to, the number of bytes to be transferred, etc. The channel descriptor is described in detail in 8.4.3 Channel Control Data Structure.

In addition to the basic transfer mode, the DMA Controller also supports two advanced transfer modes; ping-pong and scatter-gather. Ping-pong transfers are ideally suited for streaming data for high-speed peripheral communication as the DMA will be ready to retrieve the next incoming data bytes immediately while the processor core is still processing the previous ones (and similarly for outgoing communication). Scatter-gather involves executing a series of tasks from memory and allows sophisticated schemes to be implemented by software.

Using different priority levels for the channels and setting the number of bytes after which the DMA Controller re-arbitrates, it is possible to ensure that timing-critical transfers are serviced on time.

## 8.4.1 Channel Select Configuration

The channel select block allows selecting which peripheral's request lines (dma\_req, dma\_sreq) to connect to each DMA channel.

This configuration is done by software through the control registers DMA\_CH0\_CTRL through DMA\_ CH11\_CTRL, with SOURCESEL and SIGSEL components. SOURCESEL selects which peripheral to listen to and SIGSEL picks which output signals to use from the selected peripheral.

All peripherals are connected to dma\_req. When this signal is triggered, the DMA performs a number of transfers as specified by the channel descriptor (2<sup>R</sup>). The USARTs are additionally connected to the dma\_sreq line. When only dma\_sreq is asserted but not dma\_req, then the DMA will perform exactly one transfer only (given that dma\_sreq is enabled by software).

#### 8.4.2 DMA Control

#### 8.4.2.1 DMA Arbitration Rate

You can configure when the controller arbitrates during a DMA transfer. This enables you to reduce the latency to service a higher priority channel.

The controller provides four bits that configure how many AHB bus transfers occur before it re-arbitrates. These bits are known as the  $R_p$ ower bits because the value you enter,  $R_p$ , is raised to the power of two and this determines the arbitration rate. For example, if  $R_p$  = 4 then the arbitration rate is  $2^4$ , that is, the controller arbitrates every 16 DMA transfers.

The following table lists the arbitration rates.

Table 8.1. AHB Bus Transfer Arbitration Interval

R_power	Arbitrate After x DMA Transfers
p0000	x = 1
b0001	x = 2
b0010	x = 4
b0011	x = 8
b0100	x = 16
b0101	x = 32
b0110	x = 64
b0111	x = 128
b1000	x = 256
b1001	x = 512
b1010 - b1111	x = 1024

**Note:** You must take care not to assign a low-priority channel with a large R\_power because this prevents the controller from servicing high-priority requests, until it re-arbitrates.

The number of dma transfers N that need to be done is specified by the user. When  $N > 2^R$  and is not an integer multiple of  $2^R$  then the controller always performs sequences of  $2^R$  transfers until  $N < 2^R$  remain to be transferred. The controller performs the remaining N transfers at the end of the DMA cycle.

You store the value of the R\_power bits in the channel control data structure. See 8.4.3.3 Control Data Configuration for more information about the location of the R\_power bits in the data structure.

## **8.4.2.2 Priority**

When the controller arbitrates, it determines the next channel to service by using the following information:

- · the channel number
- the priority level, default or high, that is assigned to the channel.

You can configure each channel to use either the default priority level or a high priority level by setting the DMA\_CHPRIS register.

Channel number zero has the highest priority and as the channel number increases, the priority of a channel decreases. The following table lists the DMA channel priority levels in descending order of priority.

Table 8.2. DMA Channel Priority

Channel Number	Priority Level Setting	Descending Order of Channel Priority
0	High	_
1	High	_
2	High	_
3	High	_
4	High	_
5	High	_
6	High	_
7	High	_
8	High	_
9	High	_
10	High	_
11	High	_
0	Default	_
1	Default	_
2	Default	_
3	Default	_
4	Default	_
5	Default	_
6	Default	_
7	Default	_
8	Default	_
9	Default	_
10	Default	_
11	Default	Lowest-priority DMA channel

After a DMA transfer completes, the controller polls all the DMA channels that are available. The following figure shows the process it uses to determine which DMA transfer to perform next.

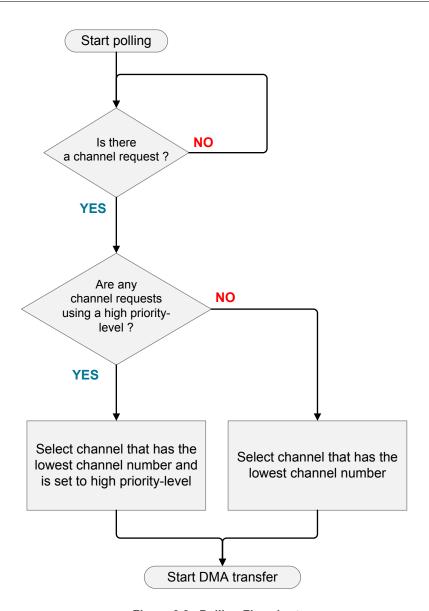

Figure 8.2. Polling Flowchart

## 8.4.2.3 DMA Cycle Types

The cycle ctrl bits control how the controller performs a DMA cycle. You can set the cycle ctrl bits as the following table lists.

Table 8.3. DMA Cycle Types

cycle_ctrl	Description	
b000	Channel control data structure is invalid	
b001	Basic DMA transfer	
b010	Auto-request	
b011	Ping-pong	
b100	Memory scatter-gather using the primary data structure	
b101	Memory scatter-gather using the alternate data structure	
b110	Peripheral scatter-gather using the primary data structure	
b111	Peripheral scatter-gather using the alternate data structure	

**Note:** The cycle\_ctrl bits are located in the channel\_cfg memory location as described in 8.4.3.3 Control Data Configuration.

For all cycle types, the controller arbitrates after  $2^R$  DMA transfers. If you set a low-priority channel with a large  $2^R$  value then it prevents all other channels from performing a DMA transfer, until the low-priority DMA transfer completes. Therefore, you must take care when setting the R\_power, that you do not significantly increase the latency for high-priority channels.

#### 8.4.2.3.1 Invalid

After the controller completes a DMA cycle it sets the cycle type to invalid, to prevent it from repeating the same DMA cycle.

#### 8.4.2.3.2 Basic

In this mode, you configure the controller to use either the primary or the alternate data structure. After you enable the channel C and the controller receives a request for this channel, then the flow for this DMA cycle is as follows:

- 1. The controller performs 2<sup>R</sup> transfers. If the number of transfers remaining becomes zero, then the flow continues at step 3.
- 2. The controller arbitrates:
  - · if a higher-priority channel is requesting service then the controller services that channel
  - if the peripheral or software signals a request to the controller, then it continues at step 1.
- 3. The controller sets dma\_done[C] HIGH for one HFCORECLK cycle. This indicates to the host processor that the DMA cycle is complete.

## 8.4.2.3.3 Auto-Request

When the controller operates in this mode, it is only necessary for it to receive a single request to enable it to complete the entire DMA cycle. This enables a large data transfer to occur, without significantly increasing the latency for servicing higher priority requests, or requiring multiple requests from the processor or peripheral.

You can configure the controller to use either the primary or the alternate data structure. After you enable the channel C and the controller receives a request for this channel, then the flow for this DMA cycle is as follows:

- 1. The controller performs 2<sup>R</sup> transfers for channel C. If the number of transfers remaining is zero the flow continues at step 3.
- 2. The controller arbitrates. When channel C has the highest priority then the DMA cycle continues at step 1.
- The controller sets dma\_done[C] HIGH for one HFCORECLK cycle. This indicates to the host processor that the DMA cycle is complete.

## 8.4.2.3.4 Ping-Pong

In ping-pong mode, the controller performs a DMA cycle using one of the data structures (primary or alternate) and it then performs a DMA cycle using the other data structure. The controller continues to switch from primary to alternate to primary... until it reads a data structure that is invalid, or until the host processor disables the channel.

Figure 8.3 Ping-Pong Example on page 87 shows an example of a ping-pong DMA transaction.

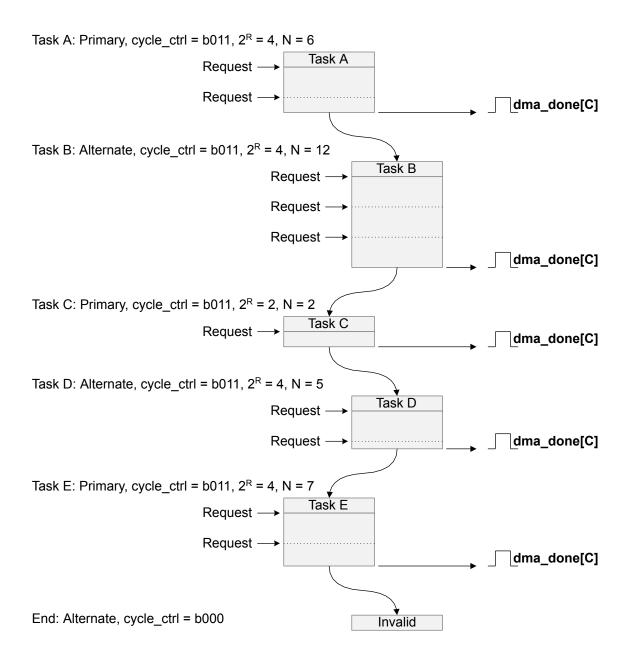

Figure 8.3. Ping-Pong Example

In Figure 8.3 Ping-Pong Example on page 87:

- Task A 1. The host processor configures the primary data structure for task A.
  - 2. The host processor configures the alternate data structure for task B. This enables the controller to immediately switch to task B after task A completes, provided that a higher priority channel does not require servicing.
  - 3. The controller receives a request and performs four DMA transfers.
  - 4. The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
  - 5. The controller performs the remaining two DMA transfers.
  - The controller sets dma done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

After task A completes, the host processor can configure the primary data structure for task C. This enables the controller to immediately switch to task C after task B completes, provided that a higher priority channel does not require servicing.

After the controller receives a new request for the channel and it has the highest priority then task B commences:

- Task B 7. The controller performs four DMA transfers.
  - 8. The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
  - 9. The controller performs four DMA transfers.
  - 10. The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
  - 11. The controller performs the remaining four DMA transfers.
  - 12. The controller sets dma done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

After task B completes, the host processor can configure the alternate data structure for task D.

After the controller receives a new request for the channel and it has the highest priority then task C commences:

- Task C 13. The controller performs two DMA transfers.
  - 14. The controller sets dma done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

After task C completes, the host processor can configure the primary data structure for task E.

After the controller receives a new request for the channel and it has the highest priority then task D commences:

- Task D 15. The controller performs four DMA transfers.
  - 16. The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
  - 17 The controller performs the remaining DMA transfer.
  - The controller sets dma\_done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

After the controller receives a new request for the channel and it has the highest priority then task E commences:

- Task E 19. The controller performs four DMA transfers.
  - 20. The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
  - 21. The controller performs the remaining three DMA transfers.
  - 22. The controller sets dma\_done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

If the controller receives a new request for the channel and it has the highest priority then it attempts to start the next task. However, because the host processor has not configured the alternate data structure, and on completion of task D the controller set the cycle\_ctrl bits to b000, then the ping-pong DMA transaction completes.

**Note:** You can also terminate the ping-pong DMA cycle in Figure 8.3 Ping-Pong Example on page 87, if you configure task E to be a basic DMA cycle by setting the cycle ctrl field to 3'b001.

#### 8.4.2.3.5 Memory Scatter-Gather

In memory scatter-gather mode the controller receives an initial request and then performs four DMA transfers using the primary data structure. After this transfer completes, it starts a DMA cycle using the alternate data structure. After this cycle completes, the controller performs another four DMA transfers using the primary data structure. The controller continues to switch from primary to alternate to primary... until either:

- · the host processor configures the alternate data structure for a basic cycle
- · it reads an invalid data structure.

**Note:** After the controller completes the N primary transfers it invalidates the primary data structure by setting the cycle\_ctrl field to b000.

The controller only asserts dma\_done[C] when the scatter-gather transaction completes using an autorequest cycle.

In scatter-gather mode, the controller uses the primary data structure to program the alternate data structure. The following table lists the fields of the channel\_cfg memory location for the primary data structure, that you must program with constant values and those that can be user defined.

Table 8.4. channel\_cfg for a Primary Data Structure, in Memory Scatter-Gather Mode

Bit	Field	Value	Description
Constant-Value Fields			
[31:30]	dst_inc	b10	Configures the controller to use word increments for the address
[29:28]	dst_size	b10	Configures the controller to use word transfers
[27:26]	src_inc	b10	Configures the controller to use word increments for the address
[25:24]	src_size	b10	Configures the controller to use word transfers
[17:14]	R_power	b0010	Configures the controller to perform four DMA transfers
[3]	next_useburst	0	For a memory scatter-gather DMA cycle, this bit must be set to zero
[2:0]	cycle_ctrl	b100	Configures the controller to perform a memory scatter-gather DMA cycle
User Defir	ned Values	'	
[23:21]	dst_prot_ctrl	_	Configures the state of HPROT when the controller writes the destination data
[20:18]	src_prot_ctrl	_	Configures the state of HPROT when the controller reads the source data
[13:4]	n_minus_1	N <sup>1</sup>	Configures the controller to perform N DMA transfers, where N is a multiple of four
Noto:	·		

#### Note:

See 8.4.3.3 Control Data Configuration for more information.

Figure 8.4 Memory Scatter-Gather Example on page 91 shows a memory scatter-gather example.

<sup>1.</sup> Because the R\_power field is set to four, you must set N to be a multiple of four. The value given by N/4 is the number of times that you must configure the alternate data structure.

Initialization:

- 1. Configure primary to enable the copy A, B, C, and D operations: cycle\_ctrl = b100, 2<sup>R</sup> = 4, N = 16.
- 2. Write the primary source data to memory, using the structure shown in the following table.

	src_data_end_ptr	dst_data_end_ptr	channel_cfg	Unused
Data for Task A	0x0A000000	0x0AE00000	cycle_ctrl = b101, 2 <sup>R</sup> = 4, N = 3	0xXXXXXXXX
Data for Task B	0x0B000000	0x0BE00000	cycle_ctrl = b101, 2 <sup>R</sup> = 2, N = 8	0xXXXXXXX
Data for Task C	0x0C000000	0x0CE00000	cycle_ctrl = b101, 2 <sup>R</sup> = 8, N = 5	0xXXXXXXXX
Data for Task D	0x0D000000	0x0DE00000	cycle_ctrl = b010, 2 <sup>R</sup> = 4, N = 4	0xXXXXXXX

Memory scatter-gather transaction:

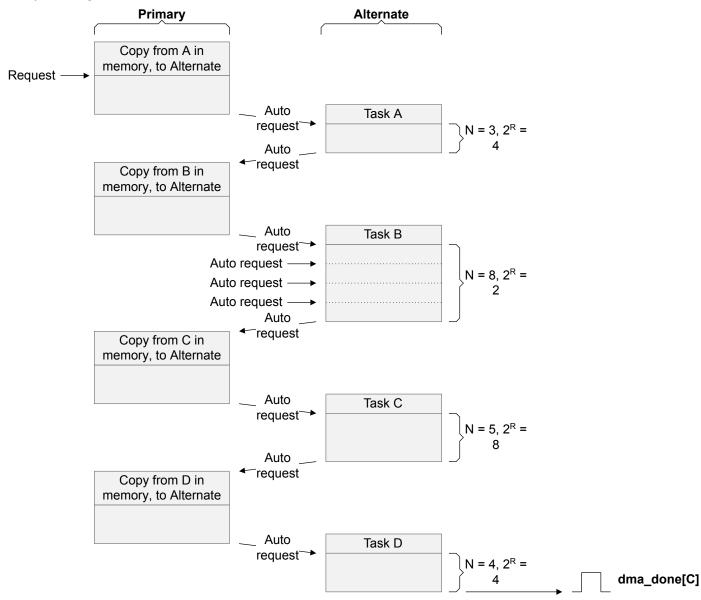

Figure 8.4. Memory Scatter-Gather Example

In Figure 8.4 Memory Scatter-Gather Example on page 91:

## Initialization

- 1. The host processor configures the primary data structure to operate in memory scatter-gather mode by setting cycle\_ctrl to b100. Because a data structure for a single channel consists of four words then you must set 2<sup>R</sup> to 4. In this example, there are four tasks and therefore N is set to 16.
- 2. The host processor writes the data structure for tasks A, B, C, and D to the memory locations that the primary src\_data\_end\_ptr specifies.
- 3. The host processor enables the channel.

The memory scatter-gather transaction commences when the controller receives a request on dma\_req[] or a manual request from the host processor. The transaction continues as follows:

Primary, copy A	1.	After receiving a request, the controller performs four DMA transfers. These transfers write the alternate data structure for task A.
	2.	The controller generates an auto-request for the channel and then arbitrates.
Task A	3.	The controller performs task A. After it completes the task, it generates an auto-request for the channel and then arbitrates.
Primary, copy B	4.	The controller performs four DMA transfers. These transfers write the alternate data structure for task B.
	5.	The controller generates an auto-request for the channel and then arbitrates.
Task B	6.	The controller performs task B. After it completes the task, it generates an auto-request for the channel and then arbitrates.
Primary, copy C	7.	The controller performs four DMA transfers. These transfers write the alternate data structure for task C.
	8.	The controller generates an auto-request for the channel and then arbitrates.
Task C	9.	The controller performs task C. After it completes the task, it generates an auto-request for the channel and then arbitrates.
Primary, copy D	10.	The controller performs four DMA transfers. These transfers write the alternate data structure for task D.
	11.	The controller sets the cycle_ctrl bits of the primary data structure to b000, to indicate that this data structure is now invalid.
	12.	The controller generates an auto-request for the channel and then arbitrates.
Task D	13.	The controller performs task D using an auto-request cycle.
	14.	The controller sets dma_done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

## 8.4.2.3.6 Peripheral Scatter-Gather

In peripheral scatter-gather mode the controller receives an initial request from a peripheral and then it performs four DMA transfers using the primary data structure. It then immediately starts a DMA cycle using the alternate data structure, without re-arbitrating.

**Note:** These are the only circumstances, where the controller does not enter the arbitration process after completing a transfer using the primary data structure.

After this cycle completes, the controller re-arbitrates and if the controller receives a request from the peripheral that has the highest priority then it performs another four DMA transfers using the primary data structure. It then immediately starts a DMA cycle using the alternate data structure, without rearbitrating. The controller continues to switch from primary to alternate to primary... until either:

- · the host processor configures the alternate data structure for a basic cycle
- · it reads an invalid data structure

**Note:** After the controller completes the N primary transfers it invalidates the primary data structure by setting the cycle\_ctrl field to b000.

The controller asserts dma\_done[C] when the scatter-gather transaction completes using a basic cycle.

In scatter-gather mode, the controller uses the primary data structure to program the alternate data structure. The following table lists the fields of the channel\_cfg memory location for the primary data structure, that you must program with constant values and those that can be user defined.

Table 8.5. channel\_cfg for a Primary Data Structure, in Peripheral Scatter-Gather Mode

Bit	Field	Value	Description
Constant-Value Fields			
[31:30]	dst_inc	b10	Configures the controller to use word increments for the address
[29:28]	dst_size	b10	Configures the controller to use word transfers
[27:26]	src_inc	b10	Configures the controller to use word increments for the address
[25:24]	src_size	b10	Configures the controller to use word transfers
[17:14]	R_power	b0010	Configures the controller to perform four DMA transfers
[2:0]	cycle_ctrl	b110	Configures the controller to perform a peripheral scatter-gather DMA cycle
User Defin	ned Values	<u> </u>	
[23:21]	dst_prot_ctrl	_	Configures the state of HPROT when the controller writes the destination data
[20:18]	src_prot_ctrl	_	Configures the state of HPROT when the controller reads the source data
[13:4]	n_minus_1	N <sup>1</sup>	Configures the controller to perform N DMA transfers, where N is a multiple of four
[3]	next_useburst	_	When set to 1, the controller sets the chnl_useburst_set [C] bit to 1 after the alternate transfer completes
Noto	<b>'</b>	L	1

#### Note:

1. Because the R\_power field is set to four, you must set N to be a multiple of four. The value given by N/4 is the number of times that you must configure the alternate data structure.

See 8.4.3.3 Control Data Configuration for more information.

Figure 8.5 Peripheral Scatter-Gather Example on page 94 shows a peripheral scatter-gather example.

Initialization:

- 1. Configure primary to enable the copy A, B, C, and D operations: cycle\_ctrl = b110, 2<sup>R</sup> = 4, N = 16.
- 2. Write the primary source data in memory, using the structure shown in the following table.

	src_data_end_ptr	dst_data_end_ptr	channel_cfg	Unused
Data for Task A	0x0A000000	0x0AE00000	cycle_ctrl = b111, 2 <sup>R</sup> = 4, N = 3	0xXXXXXXX
Data for Task B	0x0B000000	0x0BE00000	cycle_ctrl = b111, 2 <sup>R</sup> = 2, N = 8	0xXXXXXXX
Data for Task C	0x0C000000	0x0CE00000	cycle_ctrl = b111, 2 <sup>R</sup> = 8, N = 5	0xXXXXXXX
Data for Task D	0x0D000000	0x0DE00000	cycle_ctrl = b001, 2 <sup>R</sup> = 4, N = 4	0xXXXXXXX

Peripheral scatter-gather transaction:

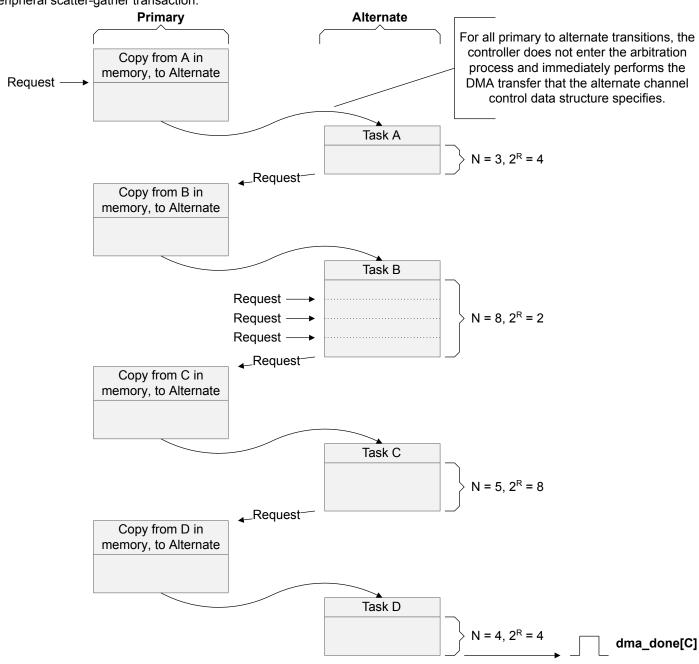

Figure 8.5. Peripheral Scatter-Gather Example

In Figure 8.5 Peripheral Scatter-Gather Example on page 94:

#### Initialization

- The host processor configures the primary data structure to operate in peripheral scatter-gather mode by setting cycle\_ctrl to b110. Because a data structure for a single channel consists of four words then you must set 2<sup>R</sup> to 4. In this example, there are four tasks and therefore N is set to 16.
- The host processor writes the data structure for tasks A, B, C, and D to the memory locations that the primary src\_data\_end\_ptr specifies.
- 3. The host processor enables the channel.

The peripheral scatter-gather transaction commences when the controller receives a request on dma\_req[]. The transaction continues as follows:

Primary, copy A 1. After receiving a request, the controller performs four DMA transfers. These transfers write the alternate data structure for task A.

Task A 2. The controller performs task A.

3. After the controller completes the task it enters the arbitration process.

After the peripheral issues a new request and it has the highest priority then the process continues with:

Primary, copy B 4. The controller performs four DMA transfers. These transfers write the alternate data structure for task B.

Task B 5. The controller performs task B. To enable the controller to complete the task, the peripheral must issue a further three requests.

6. After the controller completes the task it enters the arbitration process.

After the peripheral issues a new request and it has the highest priority then the process continues with:

Primary, copy C 7. The controller performs four DMA transfers. These transfers write the alternate data structure for task C.

Task C 8. The controller performs task C.

9. After the controller completes the task it enters the arbitration process.

After the peripheral issues a new request and it has the highest priority then the process continues with:

Primary, copy D 10. The controller performs four DMA transfers. These transfers write the alternate data structure for task D.

11. The controller sets the cycle\_ctrl bits of the primary data structure to b000, to indicate that this data structure is now invalid.

Task D 12. The controller performs task D using a basic cycle.

13. The controller sets dma\_done[C] HIGH for one HFCORECLK cycle and enters the arbitration process.

## 8.4.2.4 Error Signaling

If the controller detects an ERROR response on the AHB-Lite master interface, it:

- · disables the channel that corresponds to the ERROR
- · sets dma err HIGH.

After the host processor detects that dma\_err is HIGH, it must check which channel was active when the ERROR occurred. It can do this by:

- 1. Reading the DMA\_CHENS register to create a list of disabled channels. When a channel asserts dma\_done[] then the controller disables the channel. The program running on the host processor must always keep a record of which channels have recently asserted their dma\_done[] outputs.
- 2. It must compare the disabled channels list from step 1, with the record of the channels that have recently set their dma\_done[] outputs. The channel with no record of dma\_done[C] being set is the channel that the ERROR occurred on.

#### 8.4.3 Channel Control Data Structure

You must provide an area of system memory to contain the channel control data structure. This system memory must:

- provide a contiguous area of system memory that the controller and host processor can access
- have a base address that is an integer multiple of the total size of the channel control data structure.

Figure 8.6 Memory Map for 12 Channels, Including the Alternate Data Structure on page 96 shows the memory that the controller requires for the channel control data structure, when all 12 channels and the optional alternate data structure are in use.

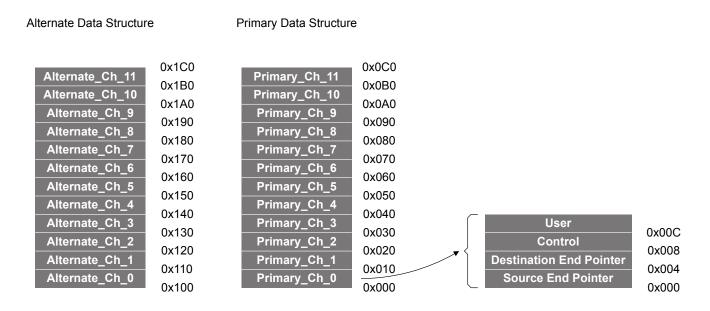

Figure 8.6. Memory Map for 12 Channels, Including the Alternate Data Structure

This structure in Figure 8.6 Memory Map for 12 Channels, Including the Alternate Data Structure on page 96 uses 384 bytes of system memory. The controller uses the lower 8 address bits to enable it to access all of the elements in the structure and therefore the base address must be at 0xXXXXXXX00.

You can configure the base address for the primary data structure by writing the appropriate value in the DMA CTRLBASE register.

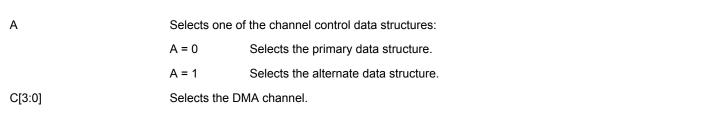

You do not need to set aside the full 384 bytes if all dma channels are not used or if all alternate descriptors are not used. If, for example, only 4 channels are used and they only need the primary descriptors, then only 64 bytes need to be set aside.

The following table lists the address bits that the controller uses when it accesses the elements of the channel control data structure.

Table 8.6. Address Bit Settings for the Channel Control Data Structure

Address Bits					
[8]	[7]	[6]	[5]	[4]	[3:0]
Α	C[3]	C[2]	C[1]	C[0]	0x0, 0x4, or 0x8

Where:

Address[3:0]	Selects one of the control elements:	
	0x0	Selects the source data end pointer.
	0x4	Selects the destination data end pointer.
	0x8	Selects the control data configuration.

0xC The controller does not access this address location. If required, you can enable the host

processor to use this memory location as system memory.

**Note:** It is not necessary for you to calculate the base address of the alternate data structure because the DMA\_ALTCTRLBASE register provides this information.

Figure 8.7 Detailed Memory Map for the 12 channels, Including the Alternate Data Structure on page 98 shows a detailed memory map of the descriptor structure.

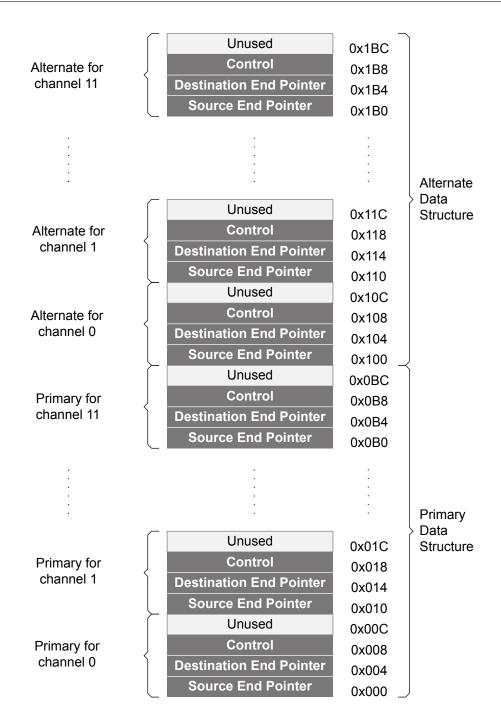

Figure 8.7. Detailed Memory Map for the 12 channels, Including the Alternate Data Structure

The controller uses the system memory to enable it to access two pointers and the control information that it requires for each channel. The following subsections will describe these 32-bit memory locations and how the controller calculates the DMA transfer address.

#### 8.4.3.1 Source Data End Pointer

The src\_data\_end\_ptr memory location contains a pointer to the end address of the source data. The following table lists the bit assignments for this memory location.

Table 8.7. src\_data\_end\_ptr Bit Assignments

Bit	Name	Description
[31:0]	src_data_end_ptr	Pointer to the end address of the source data

Before the controller can perform a DMA transfer, you must program this memory location with the end address of the source data. The controller reads this memory location when it starts a 2<sup>R</sup> DMA transfer.

Note: The controller does not write to this memory location.

#### 8.4.3.2 Destination Data End Pointer

The dst\_data\_end\_ptr memory location contains a pointer to the end address of the destination data. The following table lists the bit assignments for this memory location.

Table 8.8. dst\_data\_end\_ptr Bit Assignments

Bit	Name	Description
[31:0]	dst_data_end_ptr	Pointer to the end address of the destination data

Before the controller can perform a DMA transfer, you must program this memory location with the end address of the destination data. The controller reads this memory location when it starts a 2<sup>R</sup> DMA transfer.

Note: The controller does not write to this memory location.

# 8.4.3.3 Control Data Configuration

For each DMA transfer, the channel\_cfg memory location provides the control information for the controller. Figure 8.8 channel\_cfg Bit Assignments on page 100 shows the bit assignments for this memory location.

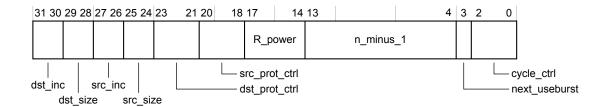

Figure 8.8. channel\_cfg Bit Assignments

Table 8.9. channel\_cfg Bit Assignments

Bit	Name	Description		
[31:30]	dst_inc	Destination address increment.		
		Source data width = byte	b00 = byte.	
			b01 = halfword.	
			b10 = word.	
			b11 = no increment. Address remains set to the value that the dst_data_end_ptr memory location contains.	
		Source data width = halfword	b00 = reserved.	
			b01 = halfword.	
			b10 = word.	
			b11 = no increment. Address remains set to the value that the dst_data_end_ptr memory location contains.	
		Source data width = word	b00 = reserved.	
			b01 = reserved.	
			b10 = word.	
			b11 = no increment. Address remains set to the value that the dst_data_end_ptr memory location contains.	
[29:28]	dst_size	Destination data size.  Note: You must set dst_size to contain the same value that src_size contains.		

Bit	Name	Description			
[27:26]	src_inc		Set the bits to control the source address increment. The address increment depends on the source data width as follows:		
		Source data width =	b00 = byte.		
		byte	b01 = halfword.		
			b10 = word.		
			b11 = no increment. Address remains set to the value that the src_data_end_ptr memory location contains.		
		Source data width =	b00 = reserved.		
		halfword	b01 = halfword.		
			b10 = word.		
			b11 = no increment. Address remains set to the value that the src_data_end_ptr memory location contains.		
		Source data width =	b00 = reserved.		
		word	b01 = reserved.		
			b10 = word.		
			b11 = no increment. Address remains set to the value that the src_data_end_ptr memory location contains.		
[25:24]	src_size	Set the bits to match the size of the source data:			
			b00 = byte		
			b01 = halfword		
			b10 = word		
			b11 = reserved.		
[23:21]	dst_prot_ctrl	Set the bits to control	the state of HPROT when the controller writes the destination data.		
		Bit [23]	This bit has no effect on the DMA.		
		Bit [22]	This bit has no effect on the DMA.		
		Bit [21]	Controls the state of HPROT as follows:		
			0 = HPROT is LOW and the access is non-privileged.		
			1 = HPROT is HIGH and the access is privileged.		
[20:18]	src_prot_ctrl	Set the bits to control the state of HPROT when the controller reads the source data.			
		Bit [20]	This bit has no effect on the DMA.		
		Bit [19] This bit has no effect on the DMA.			
		Bit [18]	Controls the state of HPROT as follows:		
			0 = HPROT is LOW and the access is non-privileged.		
			1 = HPROT is HIGH and the access is privileged.		

Bit	Name	Description			
[17:14]	R_power	Set these bits to control how many DMA transfers can occur before the controller re-arbitrates. The possible arbitration rate settings are:			
		b0000	Arbitrates after each DMA transfer.		
		b0001	Arbitrates after 2 DMA transfers.		
		b0010	Arbitrates after 4 DMA transfers.		
		b0011	Arbitrates after 8 DMA transfers.		
		b0100	Arbitrates after 16 DMA transfers.		
		b0101	Arbitrates after 32 DMA transfers.		
		b0110	Arbitrates after 64 DMA transfers.		
		b0111	Arbitrates after 128 DMA transfers.		
		b1000	Arbitrates after 256 DMA transfers.		
		b1001	Arbitrates after 512 DMA transfers.		
		b1010 - b1111	Arbitrates after 1024 DMA transfers. This means that no arbitration occurs during the DMA transfer because the maximum transfer size is 1024.		
[13:4]	n_minus_1	Prior to the DMA cycle commencing, these bits represent the total number of E fers that the DMA cycle contains. You must set these bits according to the size cycle that you require.			
		The 10-bit value indicates the number of DMA transfers, minus one. The possible values are:			
		b000000000 = 1 DMA transfer.			
		b000000001 = 2 DMA transfers.			
		b00000010 = 3 DMA transfers.			
		b00000011 = 4 DMA transfers.			
		b000000100 = 5 DMA transfers.			
		b11111111 = 1024 DMA transfers.			
		The controller updates this field immediately prior to it entering the arbitration process. This enables the controller to store the number of outstanding DMA transfers that are necessary to complete the DMA cycle.			

Bit	Name	Description			
[3]	next_useburst	Controls if the chnl_useburst_set [C] bit is set to a 1, when the controller is performing a peripheral scatter-gather and is completing a DMA cycle that uses the alternate data structure.			
		<b>Note:</b> Immediately prior to completion of the DMA cycle that the alternate data structure specifies, the controller sets the chnl_useburst_set [C] bit to 0 if the number of remaining transfers is less than 2 <sup>R</sup> . The setting of the next_useburst bit controls if the controller performs an additional modification of the chnl_useburst_set [C] bit.			
		In peripheral scatter-gather DMA cycle then after the DMA cycle that uses the alternate data structure completes, either:			
		0 = the controller does not change the value of the chnl_useburst_set [C] bit. If the chnl_useburst_set [C] bit is 0 then for all the remaining DMA cycles in the peripheral scattergather transaction, the controller responds to requests on dma_req[] and dma_sreq[], when it performs a DMA cycle that uses an alternate data structure.			
		DMA cycles in the pe	1 = the controller sets the chnl_useburst_set [C] bit to a 1. Therefore, for the remaining DMA cycles in the peripheral scatter-gather transaction, the controller only responds to requests on dma_req[], when it performs a DMA cycle that uses an alternate data structure.		
[2:0]	cycle_ctrl	The operating mode	of the DMA cycle. The modes are:		
		b000	Stop. Indicates that the data structure is invalid.		
		b001	Basic. The controller must receive a new request, prior to it entering the arbitration process, to enable the DMA cycle to complete.		
		b010	Auto-request. The controller automatically inserts a request for the appropriate channel during the arbitration process. This means that the initial request is sufficient to enable the DMA cycle to complete.		
		b011	Ping-pong. The controller performs a DMA cycle using one of the data structures. After the DMA cycle completes, it performs a DMA cycle using the other data structure. After the DMA cycle completes and provided that the host processor has updated the original data structure, it performs a DMA cycle using the original data structure. The controller continues to perform DMA cycles until it either reads an invalid data structure or the host processor changes the cycle_ctrl bits to b001 or b010. See 8.4.2.3.4 Ping-Pong.		
		b100	Memory scatter/gather. See 8.4.2.3.5 Memory Scatter-Gather.		
			When the controller operates in memory scatter-gather mode, you must only use this value in the primary data structure.		
		b101	Memory scatter/gather. See 8.4.2.3.5 Memory Scatter-Gather.		
			When the controller operates in memory scatter-gather mode, you must only use this value in the alternate data structure.		
		b110	Peripheral scatter/gather. See 8.4.2.3.6 Peripheral Scatter-Gather.		
			When the controller operates in peripheral scatter-gather mode, you must only use this value in the primary data structure.		
		b111	Peripheral scatter/gather. See 8.4.2.3.6 Peripheral Scatter-Gather.		
			When the controller operates in peripheral scatter-gather mode, you must only use this value in the alternate data structure.		

At the start of a DMA cycle, or 2<sup>R</sup> DMA transfer, the controller fetches the channel\_cfg from system memory. After it performs 2<sup>R</sup>, or N, transfers it stores the updated channel\_cfg in system memory.

The controller does not support a dst\_size value that is different to the src\_size value. If it detects a mismatch in these values, it uses the src\_size value for source and destination and when it next updates the n\_minus\_1 field, it also sets the dst\_size field to the same as the src\_size field.

After the controller completes the N transfers it sets the cycle\_ctrl field to b000, to indicate that the channel\_cfg data is invalid. This prevents it from repeating the same DMA transfer.

#### 8.4.3.4 Address Calculation

To calculate the source address of a DMA transfer, the controller performs a left shift operation on the n\_minus\_1 value by a shift amount that src\_inc specifies, and then subtracts the resulting value from the source data end pointer. Similarly, to calculate the destination address of a DMA transfer, it performs a left shift operation on the n\_minus\_1 value by a shift amount that dst\_inc specifies, and then subtracts the resulting value from the destination end pointer.

Depending on the value of src\_inc and dst\_inc, the source address and destination address can be calculated using the equations:

Pointer Values	Equation	
src_inc = b00 and dst_inc = b00	source address = src_data_end_ptr - n_minus_1	
	destination address = dst_data_end_ptr - n_minus_1	
src_inc = b01 and dst_inc = b01	source address = src_data_end_ptr - (n_minus_1 << 1)	
	destination address = dst_data_end_ptr - (n_minus_1 << 1)	
src_inc = b10 and dst_inc = b10	source address = src_data_end_ptr - (n_minus_1 << 2)	
	destination address = dst_data_end_ptr - (n_minus_1 << 2)	
src_inc = b11 and dst_inc = b11	source address = src_data_end_ptr	
	destination address = dst_data_end_ptr	

The following table lists the destination addresses for a DMA cycle of six words.

Table 8.10. DMA Cycle of Six Words Using a Word Increment

Initial values of chan	nel_cfg, prior to the DMA	cycle		
src_size = b10, dst_i	nc = b10, n_minus_1 = b1	01, cycle_ctrl = 1		
DMA transfers	End Pointer	Count	Difference <sup>1</sup>	Address
	0x2AC	5	0x14	0x298
	0x2AC	4	0x10	0x29C
	0x2AC	3	0xC	0x2A0
	0x2AC	2	0x8	0x2A4
	0x2AC	1	0x4	0x2A8
	0x2AC	0	0x0	0x2AC
Final values of chann	nel_cfg, after the DMA cyc	le	'	-
src_size = b10, dst_i	nc = b10, n_minus_1 = 0,	cycle_ctrl = 0		
Note: 1. This value is the	e result of count being shift	ed left by the value of ds	st_inc.	

The following table lists the destination addresses for a DMA transfer of 12 bytes using a halfword increment.

Table 8.11. DMA Cycle of 12 Bytes Using a Halfword Increment

Initial values of channel_cfg, prior to the DMA cycle	
src_size = b00, dst_inc = b01, n_minus_1 = b1011, cycle_ctrl = 1, R_power = b11	

DMA transfers	End Pointer	Count	Difference <sup>1</sup>	Address
	0x5E7	11	0x16	0x5D1
	0x5E7	10	0x14	0x5D3
	0x5E7	9	0x12	0x5D5
	0x5E7	8	0x10	0x5D7
	0x5E7	7	0xE	0x5D9
	0x5E7	6	0xC	0x5DB
	0x5E7	5	0xA	0x5DD
	0x5E7	4	0x8	0x5DF
Values of channel cf	g after 2 <sup>R</sup> DMA transfers	,	'	

src size = b00, dst inc = b01, n minus 1 = b011, cycle ctrl = 1, R power = b11

	End Pointer	Count	Difference	Address
	0x5E7	3	0x6	0x5E1
DMA transfers	0x5E7	2	0x4	0x5E3
	0x5E7	1	0x2	0x5E5
	0x5E7	0	0x0	0x5E7

Final values of channel cfg, after the DMA cycle

src\_size = b00, dst\_inc = b01, n\_minus\_1 = 0, cycle\_ctrl = 0<sup>2</sup>, R\_power = b11

#### Note:

- 1. This value is the result of count being shifted left by the value of dst\_inc.
- 2. After the controller completes the DMA cycle, it invalidates the channel cfg memory location by clearing the cycle ctrl field.

## 8.4.4 Looped Transfers

A regular DMA channel is done when it has performed the number of transfers given by the channel descriptor. If an application wants a continuous flow of data, one option is to use ping-pong mode, alternating between two descriptors and having software update one descriptor while the other is being used. Another way is to use looped transfers.

For DMA channels 0 and 1, looping can be enabled by setting EN in DMA\_LOOP0 and DMA\_LOOP1 respectively. A looping DMA channel will on completion set the respective DONE interrupt flag, but then reload n\_minus\_1 in the channel descriptor with the loop width defined by WIDTH in DMA\_LOOPx and continue transmitting data.

The total length of the transfer is given by the original value of n minus 1 in the channel descriptor and WIDTH in DMA LOOPx times the number of loops taken. The loop feature can for instance be used to implement a ring buffer, contiguously overwriting old data when new data is available. To end the loop clear EN in DMA\_LOOPx. The channel will then complete the last loop before stopping.

## 8.4.5 2D Copy

In addition to looped transfers, DMA channel 0 has the ability to do rectangle transfers, or 2D copy. For an application working with graphics, this would mean the ability to copy a rectangle of a given width and height from one picture to another. The DMA also has the ability to copy from linear data to a rectangle, and from a rectangle to linear data.

To set up rectangle copy for DMA channel 0, configure WIDTH in DMA\_LOOP0 to one less than the rectangle width, and HEIGHT in DMA\_RECT0 to one less than the rectangle height. Then set SRCSTRIDE in DMA\_RECT0 to the outer rectangle width of the source, and DSTSTRIDE in DMA\_RECT0 to the outer rectangle width of the destination rectangle. Finally, the channel descriptor for channel 0 has to be configured. The source and destination end pointers should be set to the last element of the first line of the source data and destination data respectively. The number of elements to be transferred, n\_minus\_1 should be set equal to WIDTH in DMA\_LOOP0. The parameters are visualized in Figure 8.9 2D Copy on page 107.

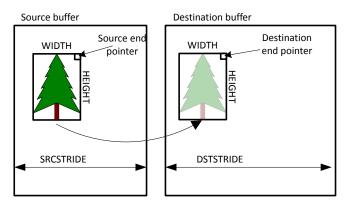

Figure 8.9. 2D Copy

When doing a rectangle copy, the source and destination address of the channel descriptor will be incremented line for line as the DMA works its way through the rectangle. The operation is done when the number of lines specified by HEIGHT in DMA\_RECTO has been copied. The source and destination addresses in the channel descriptor will then point at the last element of the source and destination rectangles.

On completion, the DONE interrupt flag of channel 0 is set. Looping is not supported for rectangle copy.

In some cases, e.g. when performing graphics operations, it is desirable to create a list of copy operations and have them executed automatically. This can be done using 2D copy together with the scatter gather mode of the DMA controller. Set DESCRECT in DMA\_CTRL to override SCRSTRIDE and HEIGHT in DMA\_RECT0 and WIDTH in DMA\_LOOP0 by the values in the user part of the DMA descriptor as shown in the following table. In this way every copy command in the list can specify these parameters individually.

Bit Field Description

[30:20] SRCSTRIDE Stride in source buffer

[19:10] HEIGHT Height - 1 of data to be copied

[9:0] WIDTH Width - 1 of data to be copied

Table 8.12. User Data Assignments When DESCRECT is Set

With regular 2D copy, the DMA descriptor will be updated as the copy operation proceeds. To be able to reuse 2D copy scatter gather list without rewriting source and destination end addresses, set PRDU in DMA\_CTRL. This will prevent the address in the descriptor from being updated. In this case RDSCH0 in DMA\_RDS must be set and all other bits in DMA\_RDS must be cleared. The bits in DMA\_RDS make individual DMA channels remember the source and destination end pointers while active, speeding up their transfers.

### 8.4.6 Interaction with the EMU

The DMA interacts with the Energy Management Unit (EMU) to allow transfers from , e.g., the LEUART to occur in EM2. The EMU can wake up the DMA sufficiently long to allow data transfers to occur. See section "DMA Support" in the LEUART documentation.

#### 8.4.7 Interrupts

The PL230 dma\_done[n:0] signals (one for each channel) as well as the dma\_err signal, are available as interrupts to the Cortex-M4 core. They are combined into one interrupt vector, DMA\_INT. If the interrupt for the DMA is enabled in the ARM Cortex-M4 core, an interrupt will be made if one or more of the interrupt flags in DMA\_IF and their corresponding bits in DMA\_IEN are set.

## 8.4.8 Examples

A basic example of how to program the DMA for transferring 42 bytes from the USART1 to memory location 0x20003420. Assumes that the channel 0 is currently disabled, and that the DMA\_ALTCTRLBASE register has already been configured.

- 1. Configure the channel select for using USART1 with DMA channel 0
  - a. Write SOURCESEL=0b001101 and SIGSEL=XX to DMA\_CHCTRL0
- 2. Configure the primary channel descriptor for DMA channel 0
  - a. Write XX (read address of USART1) to src data end ptr
  - b. Write 0x20003420 + 40 to dst data end ptr c
  - c. Write these values to channel cfg for channel 0:
    - i. dst inc=b01 (destination halfword address increment)
    - ii. dst\_size=b01 (halfword transfer size)
    - iii. src\_inc=b11 (no address increment for source)
    - iv. src size=01 (halfword transfer size)
    - v. dst prot ctrl=000 (no cache/buffer/privilege)
    - vi. src prot ctrl=000 (no cache/buffer/privilege)
    - vii. R power=b0000 (arbitrate after each DMA transfer)
    - viii. n minus 1=d20 (transfer 21 halfwords)
    - ix. next\_useburst=b0 (not applicable)
    - x. cycle ctrl=b001 (basic operating mode)
- 3. Enable the DMA
  - a. Write EN=1 to DMA CONFIG
- 4. Disable the single requests for channel 0 (i.e., do not react to data available, wait for buffer full)
  - a. Write DMA\_CHUSEBURSTS[0]=1
- 5. Enable buffer-full requests for channel 0
  - a. Write DMA CHREQMASKC[0]=1
- 6. Use the primary data structure for channel 0
  - a. Write DMA\_CHALTC[0]=1
- 7. Enable channel 0
  - a. Write DMA CHENS[0]=1

### 9. RMU - Reset Management Unit

#### **Quick Facts**

#### What?

The RMU ensures correct reset operation. It is responsible for connecting the different reset sources to the reset lines of the EFM32WG.

### Why?

A correct reset sequence is needed to ensure safe and synchronous startup of the EFM32WG. In the case of error situations such as power supply glitches or software crash, the RMU provides proper reset and startup of the EFM32WG.

#### How?

The Power-on Reset and Brown-out Detector of the EFM32WG provides power line monitoring with exceptionally low power consumption. The cause of the reset may be read from a register, thus providing software with information about the cause of the reset.

#### 9.1 Introduction

The RMU is responsible for handling the reset functionality of the EFM32WG.

#### 9.2 Features

- · Reset sources
  - Power-on Reset (POR)
  - Brown-out Detection (BOD) on the following power domains:
    - · Regulated domain
    - Unregulated domain
    - Analog Power Domain 0 (AVDD0)
    - Analog Power Domain 1 (AVDD1)
  - · RESETn pin reset
  - · Watchdog reset
  - · EM4 wakeup reset from pin
  - · EM4 wakeup reset from Backup RTC interrupt
  - · Wakeup from Backup Mode
  - Software triggered reset (SYSRESETREQ)
  - Core LOCKUP condition
- · EM4 Detection
- · A software readable register indicates the cause of the last reset

### 9.3 Functional Description

The RMU monitors each of the reset sources of the EFM32WG. If one or more reset sources go active, the RMU applies reset to the EFM32WG. When the reset sources go inactive the EFM32WG starts up. At startup the EFM32WG loads the stack pointer and program entry point from memory, and starts execution.

As seen in the figure below, the Power-on Reset, Brown-out Detectors, Watchdog timeout, and RESETn pin all reset the whole system including the Debug Interface. A Core Lockup condition or a System reset request from software resets the whole system except the Debug Interface.

Whenever a reset source is active, the corresponding bit in the RMU\_RSTCAUSE register is set. At startup the program code may investigate this register in order to determine the cause of the reset. The register must be cleared by software.

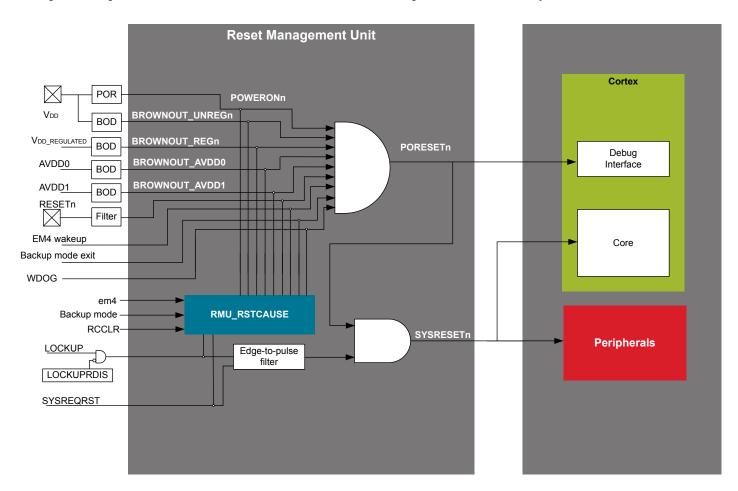

Figure 9.1. RMU Reset Input Sources and Connections

## 9.3.1 RMU\_RSTCAUSE Register

The RMU\_RSTCAUSE register indicates the reason for the last reset. The register should be cleared after the value has been read at startup. Otherwise, the register may indicate multiple causes for the reset at next startup.

The following procedure must be done to clear RMU\_RSTCAUSE:

- 1. Write a 1 to RCCLR in RMU\_CMD.
- 2. Write a 1 to bit 0 in EMU\_AUXCTRL.
- 3. Write a 0 to bit 0 in EMU\_AUXCTRL.

RMU\_RSTCAUSE should be interpreted according to the table below. X bits are don't care. Notice that it is possible to have multiple reset causes. For example, an external reset and a watchdog reset may happen simultaneously.

Table 9.1. RMU Reset Cause Register Interpretation

Register Value	Cause
0bXXXX XXXX XXXX XXX1	A Power-on Reset has been performed. X bits are don't care.
0bXXXX XXXX 0XXX XX10	A Brown-out has been detected on the unregulated power.
0bXXXX XXXX XXX0 0100	A Brown-out has been detected on the regulated power.
0bXXXX XXXX XXXX 1X00	An external reset has been applied.
0bXXXX XXXX XXX1 XX00	A watchdog reset has occurred.
0bXXXX X000 0010 0000	A lockup reset has occurred.
0bXXXX X000 01X0 0000	A system request reset has occurred.
0bXXXX X000 1XX0 0XX0	The system has woken up from EM4.
0bXXXX X001 1XX0 0XX0	The system has woken up from EM4 on an EM4 wakeup reset request from pin.
0bXXXX X01X XXX0 0000	A Brown-out has been detected on Analog Power Domain 0 (AVDD0).
0bXXXX X10X XXX0 0000	A Brown-out has been detected on Analog Power Domain 1 (AVDD1).
0bXXXX 1XXX XXXX 0XX0	A Brown-out has been detected by the Backup BOD on VDD_DREG.
0bXXX1 XXXX XXXX 0XX0	A Brown-out has been detected by the Backup BOD on BU_VIN.
0bXX1X XXXX XXXX 0XX0	A Brown-out has been detected by the Backup BOD on unregulated power
0bX1XX XXXX XXXX 0XX0	A Brown-out has been detected by the Backup BOD on regulated power.
0b1XXX XXXX XXXX XXX0	The system has been in Backup mode.

**Note:** When exiting EM4 with external reset, both the BODREGRST and BODUNREGRST in RSTCAUSE might be set (i.e., are invalid).

### 9.3.2 Power-On Reset (POR)

The POR ensures that the EFM32WG does not start up before the supply voltage  $V_{DD}$  has reached the threshold voltage VPORthr (see Device Datasheet Electrical Characteristics for details). Before the threshold voltage is reached, the EFM32WG is kept in reset state. The operation of the POR is illustrated in the figure below with the active low POWERONn reset signal. The reason for the "unknown" region is that the corresponding supply voltage is too low for any reliable operation.

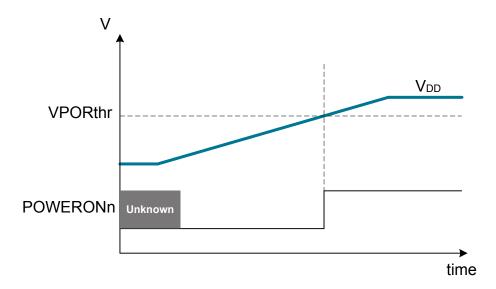

Figure 9.2. RMU Power-on Reset Operation

## 9.3.3 Brown-Out Detector Reset (BOD)

The EFM32WG has 4 brownout detectors, one for the unregulated 3.0 V power, one for the regulated internal power, one for Analog Power Domain 0 (AVDD0), and one for Analog Power Domain 1 (AVDD1). The BODs are constantly monitoring the voltages. Whenever the unregulated or regulated power drops below the VBODthr value (see Electrical Characteristics for details), or if the AVDD0 or AVDD1 drops below the voltage at the decouple pin (DEC), the corresponding active low BROWNOUTn line is held low. The BODs also include hysteresis, which prevents instability in the corresponding BROWNOUTn line when the supply is crossing the VBODthr limit or the AVDD bods drops below decouple pin (DEC). The operation of the BOD is illustrated in the figure below. The "unknown" regions are handled by the POR module.

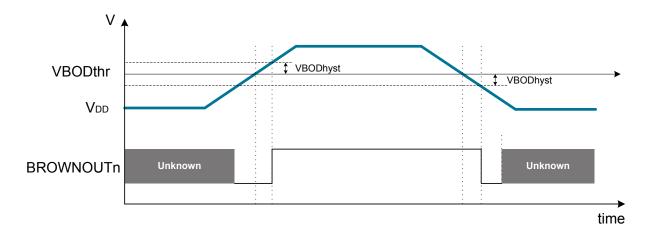

Figure 9.3. RMU Brown-out Detector Operation

## 9.3.4 RESETn Pin Reset

Forcing the RESETn pin low generates a reset of the EFM32WG. The RESETn pin includes an on-chip pull-up resistor, and can therefore be left unconnected if no external reset source is needed. Also connected to the RESETn line is a filter which prevents glitches from resetting the EFM32WG.

### 9.3.5 Watchdog Reset

The Watchdog circuit is a timer which (when enabled) must be cleared by software regularly. If software does not clear it, a Watchdog reset is activated. This functionality provides recovery from a software stalemate. Refer to the Watchdog section for specifications and description.

### 9.3.6 Lockup Reset

A Cortex-M4 lockup is the result of the core being locked up because of an unrecoverable exception following the activation of the processor's built-in system state protection hardware.

For more information about the Cortex-M4 lockup conditions, see the ARMv7-M Architecture Reference Manual. The Lockup reset does not reset the Debug Interface. Set the LOCKUPRDIS bit in the RMU CTRL register in order to disable this reset source.

### 9.3.7 System Reset Request

Software may initiate a reset (e.g. if it finds itself in a non-recoverable state). By asserting the SYSRESETREQ in the Application Interrupt and Reset Control Register (write 0x05FA 0004), a reset is issued. The SYSRESETREQ does not reset the Debug Interface.

#### 9.3.8 EM4 Reset

Whenever EM4 is entered, the EM4RST bit is set. This bit enables the user to identify that the device has been in EM4. Upon wake-up this bit should be cleared by software.

#### 9.3.9 EM4 Wakeup Reset

Whenever the system is woken up from EM4 on a pin wake-up request, the EM4WURST bit is set. This bit enables the user to identify that the device was woken up from EM4 using a pin wake-up request. Upon wake-up this bit should be cleared by software.

### 9.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

## 10. EMU - Energy Management Unit

#### **Quick Facts**

#### What?

The EMU (Energy Management Unit) handles the different low energy modes in the EFM32WG microcontrollers.

## Why?

The need for performance and peripheral functions varies over time in most applications. By efficiently scaling the available resources in real-time to match the demands of the application, the energy consumption can be kept at a minimum.

#### How?

With a broad selection of energy modes, a high number of low-energy peripherals available even in EM2, and short wakeup time (2 µs from EM2 and EM3), applications can dynamically minimize energy consumption during program execution.

#### 10.1 Introduction

The Energy Management Unit (EMU) manages all the low energy modes (EM) in EFM32WG microcontrollers. Each energy mode manages if the CPU and the various peripherals are available. The energy modes range from EM0 to EM4, where EM0, also called run mode, enables the CPU and all peripherals. The lowest recoverable energy mode, EM3, disables the CPU and most peripherals while maintaining wake-up and RAM functionality. EM4 disables everything except the POR, pin reset and optionally Backup RTC, 512 byte data retention, GPIO state retention, and EM4 reset wakeup request.

The various energy modes differ in:

- · Energy consumption
- · CPU activity
- · Reaction time
- · Wake-up triggers
- · Active peripherals
- · Available clock sources

Low energy modes EM1 to EM4 are enabled through the application software. In EM1-EM3, a range of wake-up triggers return the microcontroller back to EM0. EM4 can only return to EM0 by power on reset, external pin reset, EM4 GPIO wakeup request, or Backup RTC interrupt.

#### 10.2 Features

- · Energy Mode control from software
- · Flexible wakeup from low energy modes
- · Low wakeup time

### 10.3 Functional Description

The Energy Management Unit (EMU) is responsible for managing the wide range of energy modes available in EFM32WG. An overview of the EMU module is shown in the following figure.

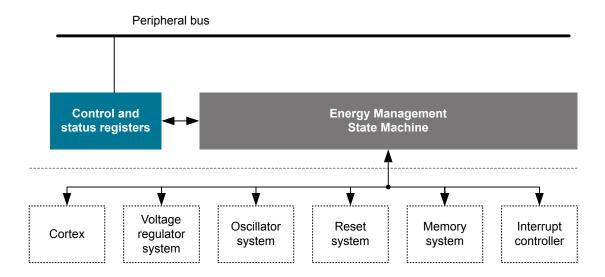

Figure 10.1. EMU Overview

The EMU is available as a peripheral on the peripheral bus. The energy management state machine is triggered from the Cortex-M4 and controls the internal voltage regulators, oscillators, memories and interrupt systems in the low energy modes. Events from the interrupt or reset systems can in turn cause the energy management state machine to return to its active state. This is further described in the following sections.

### 10.3.1 Energy Modes

There are five main energy modes available in EFM32WG, called Energy Mode 0 (EM0) through Energy Mode 4 (EM4). EM0, also called the active mode, is the energy mode in which any peripheral function can be enabled and the Cortex-M4 core is executing instructions. EM1 through EM4, also called low energy modes, provide a selection of reduced peripheral functionality that also lead to reduced energy consumption, as described below.

The following figure shows the transitions between different energy modes. After reset the EMU will always start in EM0. A transition from EM0 to another energy mode is always initiated by software. EM0 is the highest activity mode, in which all functionality is available. EM0 is therefore also the mode with highest energy consumption.

The low energy modes EM1 through EM4 result in less functionality being available, and therefore also reduced energy consumption. The Cortex-M4 is not executing instructions in any low energy mode. Each low energy mode provides different energy consumptions associated with it, for example because a different set of peripherals are enabled or because these peripherals are configured differently.

A transition from EM0 to a low energy mode can only be triggered by software.

A transition from EM1 – EM3 to EM0 can be triggered by an enabled interrupt or event. In addition, a chip reset will return the device to EM0. A transition from EM4 can be triggered by a pin reset, poweron reset, EM4 GPIO wakeup, or Backup RTC interrupt.

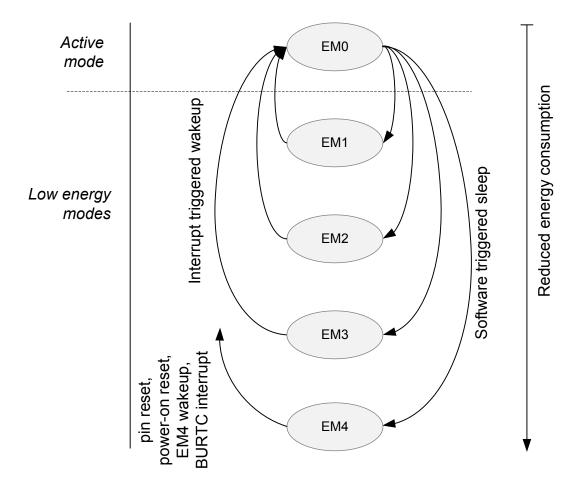

Figure 10.2. EMU Energy Mode Transitions

No direct transitions between EM1, EM2 or EM3 are available, as can also be seen from the previous figure. Instead, a wakeup will transition back to EM0, in which software can enter any other low energy mode. An overview of the supported energy modes and the functionality available in each mode is shown in the following table. Most peripheral functionality indicated as "On" in a particular energy mode can also be turned off from software in order to save further energy.

Table 10.1. EMU Energy Mode Overview

	EM0 <sup>1</sup>	EM1 <sup>2</sup>	EM2 <sup>2</sup>	EM3 <sup>2</sup>	EM4 <sup>2</sup>
Wakeup time to EM0	_	-	2 µs	2 µs	160 µs

Notes					

## Note:

- 1. Energy Mode 0/Active Mode.
- 2. Energy Mode 1/2/3/4.
- 3. When the 1 kHz ULFRCO is selected.
- 4. Not available in Backup mode.

The different Energy Modes are summarized in the following sections.

#### 10.3.1.1 EM0

- · The high frequency oscillator is active
- · High frequency clock trees are active
- · All peripheral functionality is available

#### 10.3.1.2 EM1

- · The high frequency oscillator is active
- · MCU clock tree is inactive
- · High frequency peripheral clock trees are active
- · All peripheral functionality is available

#### 10.3.1.3 EM2

- · The high frequency oscillator is inactive
- The high frequency peripheral and MCU clock trees are inactive
- · The low frequency oscillator and clock trees are active
- · Low frequency peripheral functionality is available
- · Wakeup through peripheral interrupt or asynchronous pin interrupt
- · RAM and register values are preserved
- · DAC and OPAMPs are available

#### 10.3.1.4 EM3

- · Both high and low frequency oscillators and clock trees are inactive
- Wakeup through asynchronous pin interrupts, I<sup>2</sup>C address recognition or ACMP edge interrupt
- · Watchdog and some low frequency peripherals available when ULFRCO (1 kHz clock) has been selected
- · BURTC is available.
- · All other peripheral functionality is disabled
- · RAM and register values are preserved
- · DAC and OPAMPs are available

## 10.3.1.5 EM4

- All oscillators and regulators are inactive, if Backup RTC is not enabled.
- · RAM and register values are not preserved, except for the ones located in the Backup RTC.
- · Optional GPIO state retention
- · Wakeup from Backup RTC interrupt, external pin reset, or pins that support EM4 wakeup

### 10.3.2 Entering a Low Energy Mode

A low energy mode is entered by first configuring the desired Energy Mode through the EMU\_CTRL register and the SLEEPDEEP bit in the Cortex-M4 System Control Register, see the following table. A Wait For Interrupt (WFI) or Wait For Event (WFE) instruction from the Cortex-M4 triggers the transition into a low energy mode.

The transition into a low energy mode can optionally be delayed until the lowest priority Interrupt Service Routine (ISR) is exited, if the SLEEPONEXIT bit in the Cortex-M4 System Control Register is set.

Entering the lowest energy mode, EM4, is done by writing a sequence to the EM4CTRL bitfield in the EMU\_CTRL register. Writing a zero to the EM4CTRL bitfield will restart the power sequence. EM2BLOCK prevents the EMU to enter EM2 or lower, and it will instead enter EM1.

EM3 is equal to EM2, except that the LFACLK/LFBCLK are disabled in EM3. The LFACLK/LFBCLK must be disabled by the user before entering low energy mode.

The EMVREG bit in EMU\_CTRL can be used to prevent the voltage regulator from being turned off in low energy modes. The device will then essentially stay in EM1 when entering a low energy mode.

Table 10.2. EMU Entering a Low Energy Mode

Low Energy Mode	EM4CTRL	EMVREG	EM2BLOCK	SLEEPDEEP	Cortex-M4 Instruction
EM1	0	x	x	0	WFI or WFE
EM2	0	0	0	1	WFI or WFE
EM4	Write sequence: 2, 3, 2, 3, 2, 3, 2, 3, 2	Х	X	X	X

## Note:

1. ('X' means don't care)

## 10.3.3 Leaving a Low Energy Mode

In each low energy mode a selection of peripheral units are available, and software can either enable or disable the functionality. Enabled interrupts that can cause wakeup from a low energy mode are shown in the following table. The wakeup triggers always return the EFM32 to EM0. Additionally, any reset source will return to EM0.

Table 10.3. EMU Wakeup Triggers from Low Energy Modes

Peripheral	Wakeup Trigger	EM0 <sup>1</sup>	EM1 <sup>2</sup>	EM2 <sup>2</sup>	EM3 <sup>2</sup>	EM4 <sup>2</sup>
RTC	Any enabled interrupt	_	Yes	Yes	Yes <sup>3</sup>	_
USART	Receive / transmit	_	Yes	_	_	_
UART	Receive / transmit	_	Yes	_	_	_
LEUART	Receive / transmit	_	Yes	Yes	_	_
LESENSE	Any enabled interrupt	_	Yes	Yes	Yes <sup>3</sup>	_
I <sup>2</sup> C	Any enabled interrupt	_	Yes	_	_	_
I <sup>2</sup> C	Receive address recognition	_	Yes	Yes	Yes	_
TIMER	Any enabled interrupt	_	Yes	_	_	_
LETIMER	Any enabled interrupt	_	Yes	Yes	Yes <sup>3</sup>	_
СМИ	Any enabled interrupt	_	Yes	_	_	_
DMA	Any enabled interrupt	_	Yes	_	_	_
MSC	Any enabled interrupt	_	Yes	_	_	_
DAC	Any enabled interrupt	_	Yes	_	_	_
ADC	Any enabled interrupt	_	Yes	_	_	_
AES	Any enabled interrupt	_	Yes	_	_	_
PCNT	Any enabled interrupt	_	Yes	Yes	Yes <sup>4</sup>	_
LCD	Any enabled interrupt	_	Yes	Yes	_	_
ACMP	Any enabled edge interrupt	_	Yes	Yes	Yes	_
VCMP	Any enabled edge interrupt	_	Yes	Yes	Yes	_
Pin interrupts	Asynchronous	_	Yes	Yes	Yes	_
Pin	Reset	_	Yes	Yes	Yes	Yes
EM4 wakeup on supported pins	Asynchronous	_	_	-	_	Yes
Backup RTC	Any enabled interrupt	Yes	Yes	Yes	Yes	Yes
Power	Cycle Off/On	_	Yes	Yes	Yes	Yes

## Note:

- 1. Energy Mode 0/Active Mode.
- 2. Energy mode 1/2/3/4.
- 3. When the 1 kHz ULFRCO is selected.
- 4. When using an external clock.

#### 10.3.4 Backup Power Domain

#### 10.3.4.1 Introduction

The EFM32WG has the possibility to be partly powered by a backup battery. The backup power input, BU\_VIN, is connected to a power domain in the EFM32WG containing the Backup RTC and 512 bytes of data retention, available in all energy modes. The following figure shows an overview of the backup powering scheme. During normal operation, the entire chip is powered by the main power supply. If the main power supply drains out and the Backup mode functionality is enabled, the system enters a low energy mode, equivalent to EM4, and automatically switches over to the backup power supply.

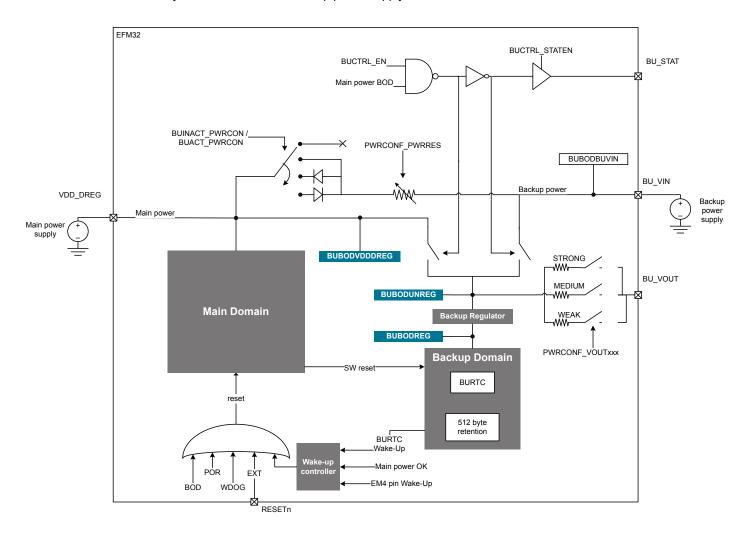

Figure 10.3. Backup Power Domain Overview

When in backup mode, available functionality is the same as the functionality available in EM4. Refer to 10.3.4.10 EM4 with RTC and Data Retention for further details.

#### 10.3.4.2 Brown Out Detectors

The backup power domain functionality utilizes four brown-out detectors, BODs. One senses the main power supply, one senses the backup power supply, one senses the unregulated selected power supply (main or backup, depending on mode), and one BOD senses the regulated power supply. The bits BUBODVDDDREG, BUBODBUVIN, BUBODUNREG, and BUBODREG in the RSTCAUSE register in the RMU are set when the associated BOD triggers. The locations of the Backup BODs are indicated in Figure 10.3 Backup Power Domain Overview on page 159. A brown out on the main power supply will trigger a switch to the backup power supply if the backup functionality is enabled and the BOD sensing on the backup power supply has not triggered. The two other BODs are used for error indication and will only set the bits in RMU\_RSTCAUSE if they are triggered.

A reset from backup mode on BUBODUNREG brown-out can also be triggered if BUMODEBODEN in EMU\_BUCTRL is set. This will cause the device to switch back to the main power supply regardless of whether this is valid or not. Set this bit to make sure the device always asssume a known condition when the backup voltage drops below the operating limits.

#### 10.3.4.3 Entering Backup Mode

To be able to enter backup mode, the EN bit in EMU\_BUCTRL has to be set. The BURDY interrupt flag will be set as soon as the backup sensing module is operational. Status of the backup functionality is also available in the BURDY flag in the EMU\_STATUS register. The BU\_VIN pin also needs to be enabled. This is done by setting the BUVINPEN bit in EMU\_ROUTE. To enter backup mode, the voltage on VDD\_DREG has to drop below the programmable threshold of the BOD sensing on this power. This threshold is programmed using BUENRANGE and BUENTHRES in EMU\_BUINACT. BUENRANGE decides the voltage range for the BOD, while BUENTHRES is used for tuning of the BOD threshold. Refer to 10.3.4.5 Threshold Calibration for details regarding BOD calibration.

Note: BUVINPEN in EMU\_ROUTE is by default set. If Backup mode is not to be used, this bit should be cleared.

Note: The voltage on BU\_VIN has to be above the threshold for the BOD sensing on BU\_VIN to enter backup mode.

The BU\_STAT pin can be used to indicate whether or not the system is in backup mode. To enable exporting of the backup mode status, set STATEN in EMU\_BUCTRL. The BU\_STAT pin is driven to BU\_VIN when backup mode is active and to ground otherwise.

## 10.3.4.4 Leaving Backup Mode

To exit backup mode, the voltage on VDD\_DREG has to be above the threshold programmed in EMU\_BUACT. BUEXRANGE decides the voltage range for backup mode exit, while BUEXTHRES is used for tuning. When leaving backup mode, a system reset is triggered, resetting everything except the backup domain. When backup mode has been active, the BURST bit in RMU\_RSTCAUSE is set.

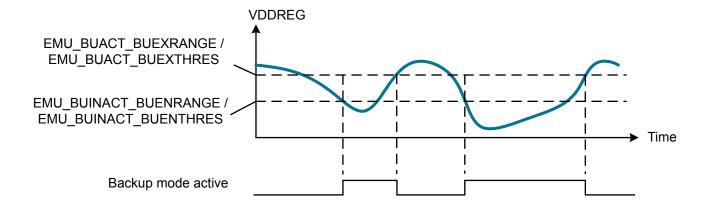

Figure 10.4. Entering and Leaving Backup Mode

The previous figure illustrates how the BOD sensing on VDD\_DREG can be programmed to implement hysteresis on entering and exiting backup mode.

#### 10.3.4.5 Threshold Calibration

The thresholds for entering and exiting backup mode are configured in the EMU\_BUINACT and EMU\_BUACT registers, respectively. Calibration of these thresholds is performed during production test, but may also be performed using the DAC. The calibration values for the BODs sensing on unregulated power and BU\_VIN, BUBODUNREG and BUBODBUVIN respectively, are available in EMU\_BUBODVINCAL and EMU\_BUBODUNREGCAL. These registers are written during production test and should not be modified except for calibrating the Backup BOD sensing on VDD\_DREG, as described in the following section.

Setting BODCAL in EMU\_BUCTRL will enable a mode where the BOD is sensing the DAC output, as depicted in the following figure. For the BODCAL bit to take effect, the backup power enable bit, EN in EMU\_BUCTRL, has to be cleared. The procedure for BOD calibration is as follows:

- 1. Clear EN and set BODCAL in EMU BUCTRL.
- 2. Store the values in EMU\_BUBODVINCAL and EMU\_BUBODUNREGCAL before clearing these registers.
- 3. Configure the DAC to output to the maximum level and wait for 500 us before configuring the DAC output to the wanted BOD trigger voltage level.
- 4. Step through the BOD calibration values (RANGE and THRES in EMU\_BUINACT) with 500 us delay in between steps until the BUBODVDDDREG flag in RMU\_RSTCAUSE is set. The RANGE and THRES values in EMU\_BUINACT can now be written to EMU\_BUINACT for configuration of threshold for entering backup mode, or EMU\_BUACT for configuration of the threshold for leaving backup mode.
- 5. Restore the values in EMU\_BUBODVINCAL and EMU\_BUBODUNREGCAL.

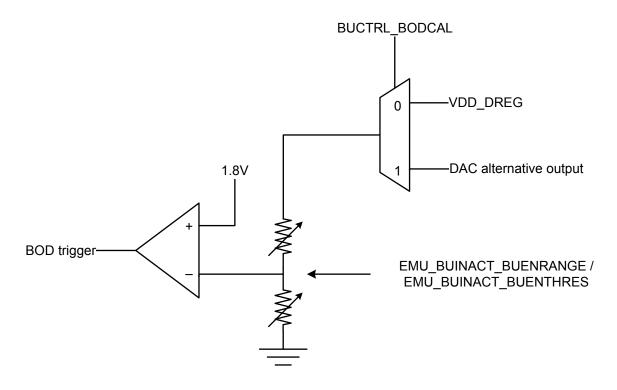

Figure 10.5. BOD Calibration Using DAC

### 10.3.4.6 Backup Battery Charging

The EFM32WG includes functionality for charging of the backup battery. This is done by connecting the main power and the backup power through a resistor, and optionally a diode. The connection is configured individually for when in backup mode and when in normal mode. When in normal mode, the connection is configured in PWRCON in EMU\_BUINACT. PWRCON in EMU\_BUACT configures the connection when in backup mode. The series resistance between the two power domains is configured in PWRRES in EMU\_PWRCONF, this configuration applies both to backup mode and normal mode.

#### 10.3.4.7 Supply Voltage Output

To be able to power external devices, the supply voltage for the backup domain is available as an output. Three switches connect the backup supply voltage to the BU\_VOUT pin. To be able to control the series resistance, the switches have different strengths: weak, medium, and strong. The switches are controlled using the VOUTWEAK, VOUTMED, and VOUTSTRONG bits in EMU\_PWRCONF. For resistor values, refer to Device Datasheet Electrical Characteristics.

### 10.3.4.8 Voltage Probing

It is possible to probe the voltage levels at VDD\_DREG, BU\_VIN, and BU\_VOUT. This is done by configuring the ADC to measure a tristated channel, for instance a disabled DAC channel. The PROBE bitfield in EMU\_BUCTRL configures which voltage to be probed. The voltage measured by the ADC will be 1/8 of the actual probed voltage, meaning that the result needs to be multiplied by 8 for the correct result. Voltage probing does not work when BODCAL in the EMU\_BUCTRL register is set.

## 10.3.4.9 Configuration Lock

Configurations used in Backup mode and EM4, like BOD calibration, and Backup RTC settings need to be locked before entering EM4, this is done by setting the LOCKCONF bit in EMU\_EM4CONF. This bit should also be set before a potential entry to backup mode. Setting this bit will lock following the configuration:

- LFXOMODE, LFXOBUFCUR, and LFXOBOOST in CMU\_CTRL
- · TUNING in CMU LFRCOCTRL
- · BURSTEN in RMU CTRL
- BURTCWU and VREGEN in EMU\_EM4CONF
- · EMU BUCTRL
- EMU\_PWRCONF
- EMU BUINACT
- EMU\_BUACT
- EMU ROUTE

**Note:** For registers residing in the CMU and EMU\_AUXCTRL, the reset value will be read after exit from EM4 or Backup mode, but if LOCKCONF in EMU\_EM4CONF has been set, the locked configuration will be used until LOCKCONF is cleared. This also applies for the LOCKCONF bit itself.

### 10.3.4.10 EM4 with RTC and Data Retention

The backup power domain can also be powered by the main power. This provides possibility for Backup RTC operation and data retention in EM4. Available functionality in EM4 is configured in EMU\_EM4CONF. Setting the VREGEN bit will keep the voltage regulator for the Backup domain enabled when in EM4. This allows the Backup RTC to keep running. To enable the Backup RTC to wake up the system from EM4, BURTCWU in EMU\_EM4CONF needs to be set. When BURTCWU is set, any enabled Backup RTC interrupt will wake up the system. For further details regarding the Backup RTC and EM4 data retention, refer to 22. BURTC - Backup Real Time Counter.

The voltage regulator can also be used to power the Backup RTC during a watchdog reset from any energy mode. Set EMU EM4CONF VREGEN to enable the Backup RTC to be powered from the regulator, making sure it survives a watchdog reset.

## 10.3.4.10.1 Oscillators in EM4

When the system is in EM4 or backup mode with the voltage regulator enabled, the ULFRCO is by default enabled. If the LFXO or LFRCO is used by the Backup RTC, the ULFRCO can be shut down to reduce power consumption. To do this, configure the OSC bitfield in EMU EM4CONF.

**Note:** If OSC in EMU\_EM4CONF is not set to ULFRCO, PRESC and LPCOMP in BURTC\_CTRL has to be configured in the following manner:

4 < (PRESC + LPCOMP) < 8, PRESC = 0,5,6,7

Refer to 22. BURTC - Backup Real Time Counter for details on how to configure the Backup RTC.

### 10.3.4.10.2 Brown Out Detector in EM4

To enable Brown-out detection in EM4, the Backup BODs have to be enabled, by setting EN in EMU\_BUCTRL. When BURDY in EMU\_STATUS is set, the Brown-out detectors are ready and able to issue a reset from EM4 if a Brown-out is detected on either regulated or unregulated power. The Backup BOD' ability to issue reset from EM4 can be disabled by setting BUBODRSTDIS in EMU\_EM4CONF.

**Note:** The Backup BODs can be enabled without allowing entrance to backup mode. This is done by setting EN in EMU\_BUCTRL, and clearing BUVINPEN in EMU\_ROUTE.

### 10.4 Register Map

The offset register address is relative to the registers base address.

## 11. CMU - Clock Management Unit

#### **Quick Facts**

#### What?

The CMU controls oscillators and clocks. EFM32WG supports five different oscillators with minimized power consumption and short start-up time. An additional separate RC oscillator is used for flash programming and debug trace. The CMU also has HW support for calibration of RC oscillators.

### Why?

Oscillators and clocks contribute significantly to the power consumption of the MCU. With the low power oscillators combined with the flexible clock control scheme, it is possible to minimize the energy consumption in any given application.

### How?

The CMU can configure different clock sources, enable/disable clocks to peripherals on an individual basis and set the prescaler for the different clocks. The short oscillator start-up times makes duty-cycling between active mode and the different low energy modes (EM2-EM4) very efficient. The calibration feature ensures high accuracy RC oscillators. Several interrupts are available to avoid CPU polling of flags.

#### 11.1 Introduction

The Clock Management Unit (CMU) is responsible for controlling the oscillators and clocks on-board the EFM32WG. The CMU provides the capability to turn on and off the clock on an individual basis to all peripheral modules in addition to enable/disable and configure the available oscillators. The high degree of flexibility enables software to minimize energy consumption in any specific application by not wasting power on peripherals and oscillators that are inactive.

### 11.2 Features

- · Multiple clock sources available:
  - 1-28 MHz High Frequency RC Oscillator (HFRCO)
  - 4-48 MHz High Frequency Crystal Oscillator (HFXO)
  - 32.768 kHz Low Frequency RC Oscillator (LFRCO)
  - · 32.768 kHz Low Frequency Crystal Oscillator (LFXO)
  - 1 kHz Ultra Low Frequency RC Oscillator (ULFRCO)
- · Low power oscillators
- · Low start-up times
- Separate prescaler for High Frequency Core Clocks (HFCORECLK) and Peripheral Clocks (HFPERCLK)
- · Individual clock prescaler selection for each Low Energy Peripheral
- · Clock Gating on an individual basis to core modules and all peripherals
- · Selectable clocks can be output on two pins for use externally.
- Auxiliary 1-28 MHz RC oscillator (AUXHFRCO) for flash programming, debug trace, and LESENSE timing.

## 11.3 Functional Description

An overview of the CMU is shown in the following figure. The number of peripheral modules that are connected to the different clocks varies from device to device.

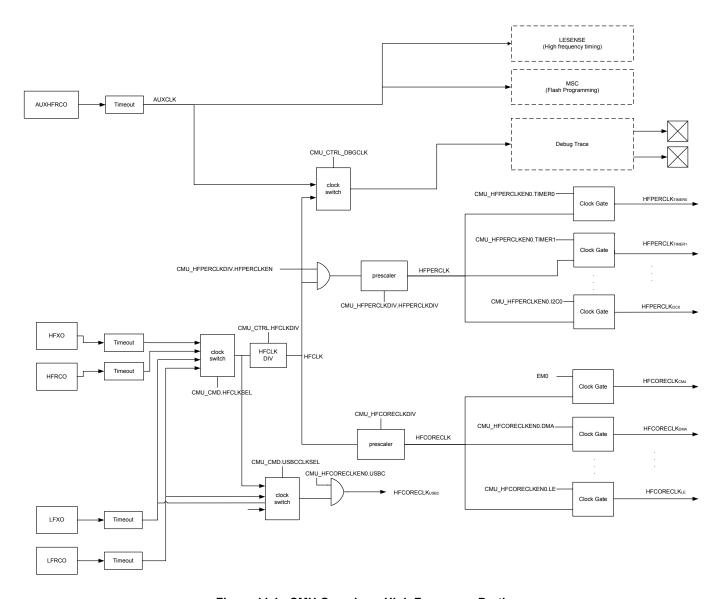

Figure 11.1. CMU Overview - High Frequency Portion

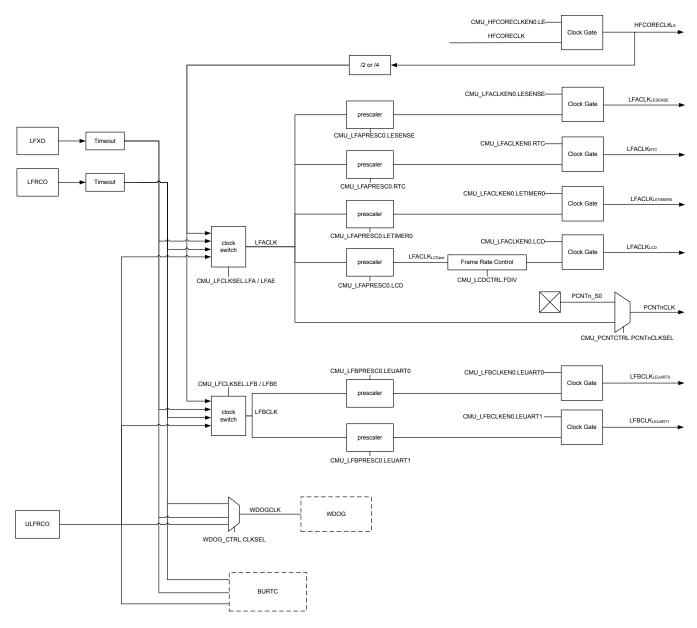

Figure 11.2. CMU Overview - Low Frequency Portion

#### 11.3.1 System Clocks

#### 11.3.1.1 HFCLK - High Frequency Clock

HFCLK is the selected High Frequency Clock. This clock is used by the CMU and drives the two prescalers that generate HFCORECLK and HFPERCLK. The HFCLK can be driven by a high-frequency oscillator (HFRCO or HFXO) or one of the low-frequency oscillators (LFRCO or LFXO). By default the HFRCO is selected. In most applications, one of the high frequency oscillators will be the preferred choice. To change the selected HFCLK write to HFCLKSEL in CMU\_CMD. The HFCLK is running in EM0 and EM1.

HFCLK can optionally be divided down by setting HFCLKDIV in CMU\_CTRL to a nonzero value. This divides down HFCLK to all high frequency components except the USB Core and is typically used to save energy in USB applications where the system is not required to run at 48 MHz. Combined with the HFCORECLK and HFPERCLK prescalers the HFCLK divider also allows for more flexible clock division.

#### 11.3.1.2 HFCORECLK - High Frequency Core Clock

HFCORECLK is a prescaled version of HFCLK. This clock drives the Core Modules, which consists of the CPU and modules that are tightly coupled to the CPU, e.g. MSC, DMA etc. This also includes the interface to the Low Energy Peripherals. Some of the modules that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific module in CMU\_HFCORECLKENO. The frequency of HFCORECLK is set using the CMU\_HFCORECLKDIV register. The setting can be changed dynamically and the new setting takes effect immediately.

The USB Core clock (USBC) is always undivided regardless of the HFCLKDIV setting. When the USB Core is active this clock must be switched to a 32 kHz clock (LFRCO or LFXO) when entering EM2. The USB Core uses this clock for monitoring the USB bus. The switch is done by writing USBCCLKSEL in CMU\_CMD. The currently active clock can be checked by reading CMU\_STATUS. The clock switch can take up to 1.5 32 kHz cycle (45 us). To avoid polling the clock selection status when switching switching from 32 kHz to HFCLK when coming up from EM2 the USBCHFCLKSEL interrupt can be used. EM3 is not supported when the USB is active.

**Note:** Note that if HFPERCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to peripheral modules will increase with the ratio between the clocks. Please refer to 5.2.3.2 Access Performance for more details.

### 11.3.1.3 HFPERCLK - High Frequency Peripheral Clock

Like HFCORECLK, HFPERCLK can also be a prescaled version of HFCLK. This clock drives the High-Frequency Peripherals. All the peripherals that are driven by this clock can be clock gated completely when not in use. This is done by clearing the clock enable bit for the specific peripheral in CMU\_HFPERCLKENO. The frequency of HFPERCLK is set using the CMU\_HFPERCLKDIV register. The setting can be changed dynamically and the new setting takes effect immediately.

**Note:** Note that if HFPERCLK runs faster than HFCORECLK, the number of clock cycles for each bus-access to peripheral modules will increase with the ratio between the clocks. E.g. if a bus-access normally takes three cycles, it will take 9 cycles if HFPERCLK runs three times as fast as the HFCORECLK.

#### 11.3.1.4 LFACLK - Low Frequency A Clock

LFACLK is the selected clock for the Low Energy A Peripherals. There are four selectable sources for LFACLK: LFRCO, LFXO, HFCORECLK/2 and ULFRCO. In addition, the LFACLK can be disabled. From reset, the LFACLK source is set to LFRCO. However, note that the LFRCO is disabled from reset. The selection is configured using the LFA field in CMU\_LFCLKSEL. The HFCORECLK/2 setting allows the Low Energy A Peripherals to be used as high-frequency peripherals.

Note: If HFCORECLK/2 is selected as LFACLK, the clock will stop in EM2/3.

Each Low Energy Peripheral that is clocked by LFACLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFAPRESC0 and the clock enable bits can be found in CMU\_LFACLKEN0. Notice that the LCD has an additional high resolution prescaler for Frame Rate Control, configured by FDIV in CMU\_LCDCTRL. When operating in oversampling mode, the pulse counters are clocked by LFACLK. This is configured for each pulse counter (n) individually by setting PCNTnCLKSEL in CMU\_PCNTCTRL.

## 11.3.1.5 LFBCLK - Low Frequency B Clock

LFBCLK is the selected clock for the Low Energy B Peripherals. There are four selectable sources for LFBCLK: LFRCO, LFXO, HFCORECLK/2 and ULFRCO. In addition, the LFBCLK can be disabled. From reset, the LFBCLK source is set to LFRCO. However, note that the LFRCO is disabled from reset. The selection is configured using the LFB field in CMU\_LFCLKSEL. The HFCORECLK/2 setting allows the Low Energy B Peripherals to be used as high-frequency peripherals.

Note: If HFCORECLK/2 is selected as LFBCLK, the clock will stop in EM2/3.

Each Low Energy Peripheral that is clocked by LFBCLK has its own prescaler setting and enable bit. The prescaler settings are configured using CMU\_LFBPRESC0 and the clock enable bits can be found in CMU\_LFBCLKEN0.

### 11.3.1.6 PCNTnCLK - Pulse Counter n Clock

Each available pulse counter is driven by its own clock, PCNTnCLK where n is the pulse counter instance number. Each pulse counter can be configured to use an external pin (PCNTn S0) or LFACLK as PCNTnCLK.

#### 11.3.1.7 WDOGCLK - Watchdog Timer Clock

The Watchdog Timer (WDOG) can be configured to use one of three different clock sources: LFRCO, LFXO or ULFRCO. (Ultra Low Frequency RC Oscillator) is a separate 1 kHz RC oscillator that also runs in EM3.

## 11.3.1.8 AUXCLK - Auxiliary Clock

AUXCLK is a 1-28 MHz clock driven by a separate RC oscillator, AUXHFRCO. This clock is used for flash programming, and Serial Wire Output (SWO), and LESENSE operation. During flash programming, or if needed by LESENSE, this clock will be active. If the AUXHFRCO has not been enabled explicitly by software, the MSC or LESENSE module will automatically start and stop it. The AUXHFRCO is enabled by writing a 1 to AUXHFRCOEN in CMU OSCENCMD. This explicit enabling is required when SWO is used.

#### 11.3.2 Oscillator Selection

#### 11.3.2.1 Start-Up Time

The different oscillators have different start-up times. For the RC oscillators, the start-up time is fixed, but both the LFXO and the HFXO have configurable start-up time. At the end of the start-up time a ready flag is set to indicated that the start-up time has exceeded and that the clock is available. The low start-up time values can be used for an external clock source of already high quality, while the higher start-up times should be used when the clock signal is coming directly from a crystal. The start-up time for HFXO and LFXO can be set by configuring the HFXOTIMEOUT and LFXOTIMEOUT bitfields, respectively. Both bitfields are located in CMU\_CTRL. For HFXO it is also possible to enable a glitch detection filter by setting HFXOGLITCHDETEN in CMU\_CTRL. The glitch detector will reset the start-up counter if a glitch is detected, making the start-up process start over again.

There are individual bits for each oscillator indicating the status of the oscillator:

- · ENABLED Indicates that the oscillator is enabled
- · READY Start-up time is exceeded
- · SELECTED Start-up time is exceeded and oscillator is chosen as clock source

These status bits are located in the CMU STATUS register.

## 11.3.2.2 Switching Clock Source

The HFRCO oscillator is a low energy oscillator with extremely short wake-up time. Therefore, this oscillator is always chosen by hardware as the clock source for HFCLK when the device starts up (e.g. after reset and after waking up from EM2 and EM3). After reset, the HFRCO frequency is 14 MHz.

Software can switch between the different clock sources at run-time. E.g., when the HFRCO is the clock source, software can switch to HFXO by writing the field HFCLKSEL in the CMU\_CMD command register. See the following figure for a description of the sequence of events for this specific operation.

**Note:** It is important first to enable the HFXO since switching to a disabled oscillator will effectively stop HFCLK and only a reset can recover the system.

During the start-up period HFCLK will stop since the oscillator driving it is not ready. This effectively stalls the Core Modules and the High-Frequency Peripherals. It is possible to avoid this by first enabling the HFXO and then wait for the oscillator to become ready before switching the clock source. This way, the system continues to run on the HFRCO until the HFXO has timed out and provides a reliable clock. This sequence of events is shown in Figure 11.4 CMU Switching from HFRCO to HFXO After HFXO is Ready on page 181.

A separate flag is set when the oscillator is ready. This flag can also be configured to generate an interrupt.

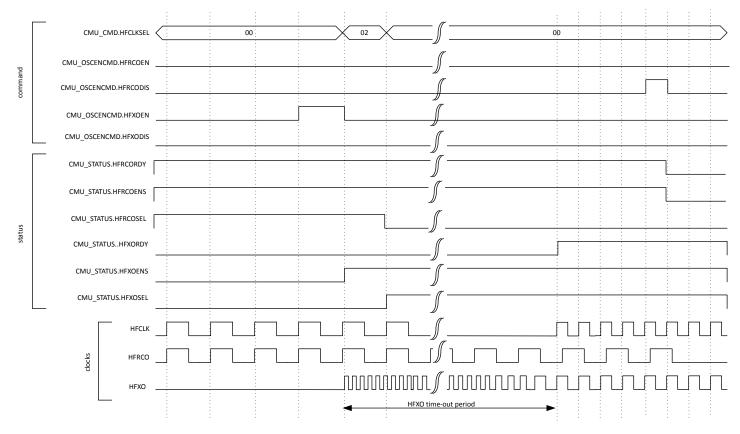

Figure 11.3. CMU Switching from HFRCO to HFXO Before HFXO is Ready

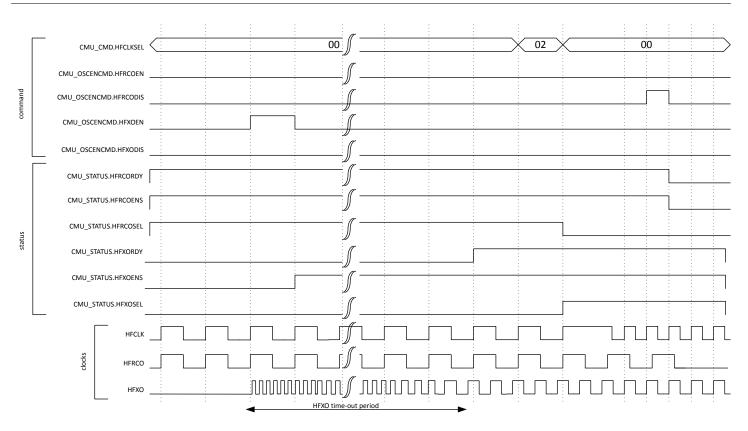

Figure 11.4. CMU Switching from HFRCO to HFXO After HFXO is Ready

Switching clock source for LFACLK and LFBCLK is done by setting the LFA and LFB fields in CMU\_LFCLKSEL. To ensure no stalls in the Low Energy Peripherals, the clock source should be ready before switching to it.

Note: To save energy, remember to turn off all oscillators not in use.

#### 11.3.3 Oscillator Configuration

#### 11.3.3.1 HFXO and LFXO

The crystal oscillators are by default configured to ensure safe startup and operation of the most common crystals. In order to optimize startup margin, startup time and power consumption for a given crystal, it is possible to adjust the gain in the oscillator. HFXO gain can be increased by setting HFXOBOOST field in CMU\_CTRL, LFXO gain can be increased by setting LFXOBOOST field in CMU\_CTRL. It is important that the boost settings, along with the crystal load capacitors are matched to the crystals in use. Correct values for these parameters can be found using Hardware Configurator in Simplicity Studio.

The HFXO crystal is connected to the HFXTAL\_N/HFXTAL\_P pins as shown in the following figure.

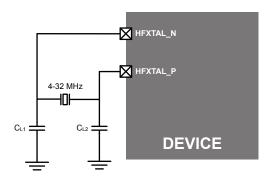

Figure 11.5. HFXO Pin Connection

Similarly, the LFXO crystal is connected to the LFXTAL\_N/LFXTAL\_P pins as shown in the following figure.

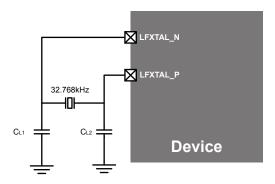

Figure 11.6. LFXO Pin Connection

It is possible to connect an external clock source to HFXTAL\_N/LFXTAL\_N pin of the HFXO or LFXO oscillator. By configuring the HFXOMODE/LFXOMODE fields in CMU\_CTRL, the HFXO/LFXO can be bypassed.

#### 11.3.3.2 HFRCO, LFRCO, and AUXHFRCO

It is possible to calibrate the HFRCO, LFRCO and AUXHFRCO to achieve higher accuracy (see the device datasheets for details on accuracy). The frequency is adjusted by changing the TUNING fields in CMU\_HFRCOCTRL/CMU\_LFRCOCTRL/CMU\_AUXHFRCOCTRL. Changing to a higher value will result in a higher frequency. Please refer to the datasheet for stepsize details.

The HFRCO and AUXHFRCO can be set to one of several different frequency bands from 1 MHz to 28 MHz by setting the BAND field in CMU\_HFRCOCTRL and CMU\_AUXHFRCOCTRL. The HFRCO and AUXHFRCO frequency bands are calibrated during production test, and the production tested calibration values can be read from the Device Information (DI) page. The DI page contains a separate tuning value for each frequency band. During reset, HFRCO and AUXHFRCO tuning values are set to the production calibrated values for the 14 MHz band, which is the default frequency band. When changing to a different HFRCO or AUXHFRCO band, make sure to also update the tuning value.

The LFRCO and is also calibrated in production and its TUNING value is set to the correct value during reset.

The CMU has built-in HW support to efficiently calibrate the RC oscillators at run-time, see the following figure. The concept is to select a reference and compare the RC frequency with the reference frequency. When the calibration circuit is started, one down-counter running on a selectable clock (DOWNSEL in CMU\_CALCTRL) and one up-counter running on a selectable clock (UPSEL in CMU\_CALCTRL) are started simultaneously. The top value for the down-counter must be written to CMU\_CALCNT before calibration is started. The smallest value that can be written to the CMU\_CALCNT is 1. The down-counter counts for CMU\_CALCNT+1 cycles. When the down-counter has reached 0, the up-counter is sampled and the CALRDY interrupt flag is set. If CONT in CMU\_CALCTRL is cleared, the counters are stopped at this point. If continuous mode is selected by setting CONT in CMU\_CALCTRL the down-counter reloads the top value and continues counting and the up-counter restarts from 0. Software can then read out the sampled up-counter value from CMU\_CALCNT. Then it is easy to find the ratio between the reference and the oscillator subject to the calibration. Overflows of the up-counter will not occur. If the up-counter reaches its top value before the down counter reaches 0, the top counter stays at its top value. Calibration can be stopped by writing CALSTOP in CMU\_CMD. With this HW support, it is simple to write efficient calibration algorithms in software.

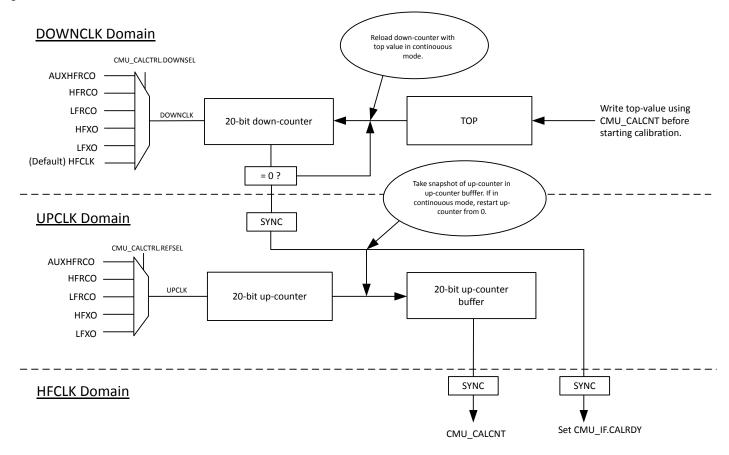

Figure 11.7. HW Support for RC Oscillator Calibration

The counter operation for single and continuous mode are shown in the following figures.

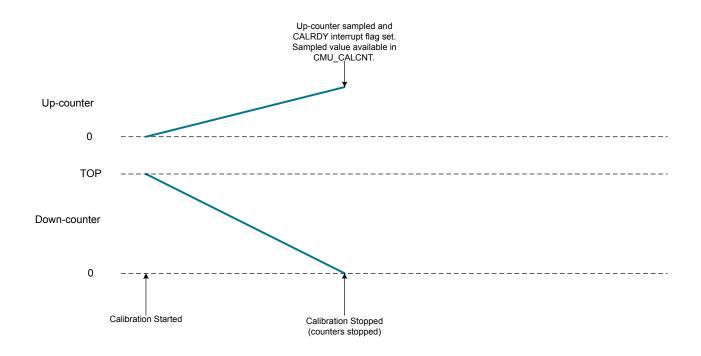

Figure 11.8. Single Calibration (CONT=0)

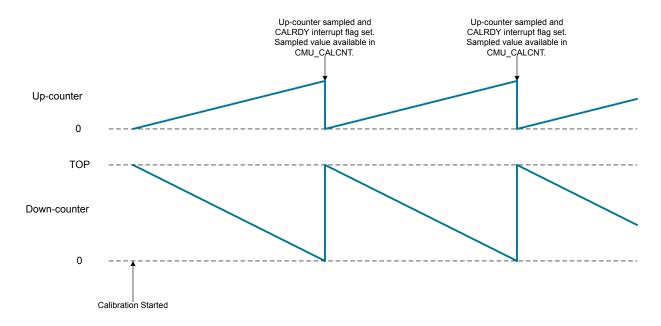

Figure 11.9. Continuous Calibration (CONT=1)

#### 11.3.4 Configuration For Operating Frequencies

The HFXO is capable of driving crystals up to 48 MHz, which allows the EFM32 to run at up to this frequency. Different frequencies have different requirements as shown in the following table. Before going to a high frequency, make sure the registers in the table have the correct values. When going down in frequency, make sure to keep the registers at the values required by the higher frequency until after the switch has been done.

Table 11.1. Table 11.1. Configuration For Operating Frequencies

Maximum Frequency	MODE in MSC_READCTRL	HFLE in CMU_CTRL	HFXOBUFCUR in CMU_CTRL
16 MHz	WS0 / WS0SCBTP / WS1 / WS1SCBTP / WS2 / WS2SCBTP	_	BOOSTUPTO32MHZ (default value)
24 MHz	WS1 / WS1SCBTP / WS2 / WS2SCBTP	_	BOOSTUPTO32MHZ (default value)
32 MHz	WS1 / WS1SCBTP / WS2 / WS2SCBTP	1	BOOSTUPTO32MHZ (default value)
48 MHz	WS2 / WS2SCBTP	1	BOOSTABOVE32MHZ

MODE in MSC\_READCTRL makes sure the flash is able to operate at the given frequencies by inserting waitstates for flash accesses. HFXOBUFCUR in CMU\_CTRL should be set to BOOSTABOVE32MHZ when operating above 32 MHz. When operating at 32 MHz or below, the default value (BOOSTUPTO32MHZ) should be used. HFLE in CMU\_CTRL is only required for frequencies above 24 MHz, and ensures correct operation of LE peripherals. The CMU\_CTRL\_HFLE is or'ed with HFCORECLKLEDIV in CMU\_HFCORECLKDIV, so setting either of this bits will reduce the the frequency of CMU\_HFCORECLKLEDIV2.

#### 11.3.5 Output Clock on a Pin

It is possible to configure the CMU to output clocks on two pins. This clock selection is done using CLKOUTSEL0 and CLKOUTSEL1 fields in CMU\_CTRL. The output pins must be configured in the CMU\_ROUTE register.

- LFRCO, LFXO, HFCLK or the qualified clock from any of the oscillators can be output on one pin (CMU\_OUT1). A qualified clock will not have any glitches or skewed duty-cycle during startup. For LFXO and HFXO you need to configure LFXOTIMEOUT and HFXOTIMEOUT in CMU CTRL correctly to guarantee a qualified clock.
- HFRCO, HFXO, HFCLK/2, HFCLK/4, HFCLK/8, HFCLK/16, ULFRCO or AUXHFRCO can be output on another pin (CMU OUT0)

Note that HFXO and HFRCO clock outputs to pin can be unstable after startup and should not be output on a pin before HFXORDY/ HFRCORDY is set high in CMU STATUS.

#### 11.3.6 Protection

It is possible to lock the control- and command registers to prevent unintended software writes to critical clock settings. This is control-led by the CMU\_LOCK register.

## 11.4 Register Map

The offset register address is relative to the registers base address.

16:12	SUDELAY	0x00	RW	HFRCO Start-up Delay
	Always write this field	to 0.		
11	Reserved	To ensure contions.	mpatibility v	with future devices, always write bits to 0. More information in 2.1 Conven-
10:8	BAND	0x3	RW	HFRCO Band Select

Write this field to set the frequency band in which the HFRCO is to operate. When changing this setting there will be no glitches on the HFRCO output, hence it is safe to change this setting even while the system is running on the HFRCO. To ensure an accurate frequency, the HFTUNING value should also be written when changing the frequency band. The calibrated tuning value for the different bands can be read from the Device Information page.

Value	Mode		Description
0	1MHZ		1 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
1	7MHZ		7 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
2	11MHZ		11 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
3	14MHZ		14 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
4	21MHZ		21 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
5	28MHZ		28 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
TUNING	0x80	RW	HFRCO Tuning Value

Writing this field adjusts the HFRCO frequency (the higher value, the higher frequency). This field is updated with the production calibrated value for the 14 MHz band during reset, and the reset value might therefore vary between devices.

7:0

10:8	BAND	0x0	RW	AUXHFRCO Band Select

Write this field to set the frequency band in which the AUXHFRCO is to operate. When changing this setting there will be no glitches on the AUXHFRCO output, hence it is safe to change this setting even while the system is using the AUXHFRCO. To ensure an accurate frequency, the AUXTUNING value should also be written when changing the frequency band. The calibrated tuning value for the different bands can be read from the Device Information page. Flash erase and write use this clock. If it is changed to another value than the default, MSC\_TIMEBASE must also be configured to ensure correct flash erase and write operation.

Value	Mode		Description
0	14MHZ		14 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
1	11MHZ		11 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
2	7MHZ		7 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
3	1MHZ		1 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
6	28MHZ		28 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
7	21MHZ		21 MHz band. NOTE: Also set the TUNING value (bits 7:0) when changing band.
TUNING	0x80	RW	AUXHFRCO Tuning Value

Writing this field adjusts the AUXHFRCO frequency (the higher value, the higher frequency). This field is updated with the production calibrated value during reset, and the reset value might therefore vary between devices.

## 12. WDOG - Watchdog Timer

#### **Quick Facts**

## What?

The WDOG (Watchdog Timer) resets the system in case of a fault condition, and can be enabled in all energy modes as long as the low frequency clock source is available.

## Why?

If a software failure or external event renders the MCU unresponsive, a Watchdog timeout will reset the system to a known, safe state.

### How?

An enabled Watchdog Timer implements a configurable timeout period. If the CPU fails to re-start the Watchdog Timer before it times out, a full system reset will be triggered. The Watchdog consumes insignificant power, and allows the device to remain safely in low energy modes for up to 256 seconds at a time.

#### 12.1 Introduction

The purpose of the watchdog timer is to generate a reset in case of a system failure, to increase application reliability. The failure may e.g. be caused by an external event, such as an ESD pulse, or by a software failure.

## 12.2 Features

- · Clock input from selectable oscillators
  - · Internal 32.768 kHz RC oscillator
  - Internal 1 kHz RC oscillator
  - External 32.768 kHz XTAL oscillator
- Configurable timeout period from 9 to 256k watchdog clock cycles
- Individual selection to keep running or freeze when entering EM2 or EM3
- · Selection to keep running or freeze when entering debug mode
- · Selection to block the CPU from entering Energy Mode 4
- Selection to block the CMU from disabling the selected watchdog clock

## 12.3 Functional Description

The watchdog is enabled by setting the EN bit in WDOG\_CTRL. When enabled, the watchdog counts up to the period value configured through the PERSEL field in WDOG\_CTRL. If the watchdog timer is not cleared to 0 (by writing a 1 to the CLEAR bit in WDOG\_CMD) before the period is reached, the chip is reset. If a timely clear command is issued, the timer starts counting up from 0 again. The watchdog can optionally be locked by writing the LOCK bit in WDOG\_CTRL. Once locked, it cannot be disabled or reconfigured by software.

The watchdog counter is reset when EN is reset.

#### 12.3.1 Clock Source

Three clock sources are available for use with the watchdog, through the CLKSEL field in WDOG\_CTRL. The corresponding clocks must be enabled in the CMU. The SWOSCBLOCK bit in WDOG\_CTRL can be written to prevent accidental disabling of the selected clocks. Also, setting this bit will automatically start the selected oscillator source when the watchdog is enabled. The PERSEL field in WDOG\_CTRL is used to divide the selected watchdog clock, and the timeout for the watchdog timer can be calculated like this:

$$T_{\mathsf{TIMEOUT}} = \frac{2^{3 + \mathsf{PERSEL}} + 1}{f}$$

where f is the frequency of the selected clock.

It is recommended to clear the watchdog first if PERSEL is changed while the watchdog is enabled.

To use this module, the LE interface clock must be enabled in CMU HFCORECLKEN0, in addition to the module clock.

## 12.3.2 Debug Functionality

The watchdog timer can either keep running or be frozen when the device is halted by a debugger. This configuration is done through the DEBUGRUN bit in WDOG CTRL. When code execution is resumed, the watchdog will continue counting where it left off.

## 12.3.3 Energy Mode Handling

The watchdog timer can be configured to either keep on running or freeze when entering EM2 or EM3. The configuration is done individually for each energy mode in the EM2RUN and EM3RUN bits in WDOG\_CTRL. When the watchdog has been frozen and is reentering an energy mode where it is running, the watchdog timer will continue counting where it left off. For the watchdog there is no difference between EM0 and EM1. The watchdog does not run in EM4, and if EM4BLOCK in WDOG\_CTRL is set, the CPU is prevented from entering EM4.

**Note:** If the WDOG is clocked by the LFXO or LFRCO, writing the SWOSCBLOCK bit will effectively prevent the CPU from entering EM3. When running from the ULFRCO, writing the SWOSCBLOCK bit will prevent the CPU from entering EM4.

## 12.3.4 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to 5.2.4 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals. note that clearing the EN bit in WDOG\_CTRL will reset the WDOG module, which will halt any ongoing register synchronization.

**Note:** Never write to the WDOG registers when it is disabled, except to enable it by setting the EN bitfield in WDOG\_CTRL. Make sure that the enable is registered (i.e. WDOG\_SYNCBUSY\_CTRL goes low), before writing other registers.

## 12.4 Register Map

## 13. PRS - Peripheral Reflex System

## **Quick Facts**

## What?

The PRS (Peripheral Reflex System) allows configurable, fast and autonomous communication between the peripherals.

## Why?

Events and signals from one peripheral can be used as input signals or triggers by other peripherals and ensure timing-critical operation and reduced software overhead.

#### How?

Without CPU intervention the peripherals can send reflex signals (both pulses and level) to each other in single- or chained steps. The peripherals can be set up to perform actions based on the incoming reflex signals. This results in improved system performance and reduced energy consumption.

## 13.1 Introduction

The Peripheral Reflex System (PRS) system is a network which allows the different peripheral modules to communicate directly with each other without involving the CPU. Peripheral modules which send out reflex signals are called producers. The PRS routes these reflex signals to consumer peripherals which apply actions depending on the reflex signals received. The format for the reflex signals is not given, but edge triggers and other functionality can be applied by the PRS.

## 13.2 Features

- · 12 configurable interconnect channels
  - · Each channel can be connected to any producing peripheral
  - · Consumers can choose which channel to listen to
  - Selectable edge detector (rising, falling and both edges)
- · Software controlled channel output
  - · Configurable level
  - Triggered pulses

## 13.3 Functional Description

An overview of the PRS module is shown in Figure 13.1 PRS Overview on page 227. The PRS contains 12 interconnect channels, and each of these can select between all the output reflex signals offered by the producers. The consumers can then choose which PRS channel to listen to and perform actions based on the reflex signals routed through that channel. The reflex signals can be both pulse signals and level signals. Synchronous PRS pulses are one HFPERCLK cycle long, and can either be sent out by a producer (e.g., ADC conversion complete) or be generated from the edge detector in the PRS channel. Level signals can have an arbitrary waveform (e.g., Timer PWM output).

## 13.3.1 Asynchronous Mode

Many reflex signals can operate in two modes, synchronous or asynchronous. A synchronous reflex is clocked on HFPERCLK, and can be used as an input to all reflex consumers, but since they require HFPERCLK, they will not work in EM2/EM3.

Asynchronous reflexes are not clocked on HFPERCLK, and can be used even in EM2/EM3. There is a limitation to reflexes operating in asynchronous mode though: they can only be used by a subset of the reflex consumers, the ones marked with async support in Table 13.2 Reflex Consumers on page 230. Peripherals that can produce asynchronous reflexes are marked with async support in Table 13.1 Reflex Producers on page 228. To use these reflexes asynchronously, set ASYNC in the CHCTRL register for the PRS channel selecting the reflex signal.

Note: If a peripheral channel with ASYNC set is used in a consumer not supporting asynchronous reflexes, the behaviour is undefined.

#### 13.3.2 Channel Functions

Different functions can be applied to a reflex signal within the PRS. Each channel includes an edge detector to enable generation of pulse signals from level signals. It is also possible to generate output reflex signals by configuring the SWPULSE and SWLEVEL bits. SWLEVEL is a programmable level for each channel and holds the value it is programmed to. The SWPULSE will give out a one-cycle high pulse if it is written to 1, otherwise a 0 is asserted. The SWLEVEL and SWPULSE signals are then XOR'ed with the selected input from the producers to form the output signal sent to the consumers listening to the channel.

**Note:** The edge detector controlled by EDSEL should only be used when working with synchronous reflexes, i.e., ASYNC in CHCTRL is cleared.

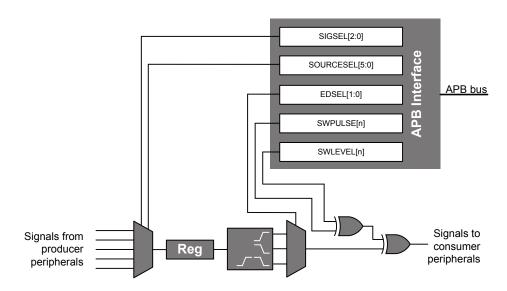

Figure 13.1. PRS Overview

## 13.3.3 Producers

Each PRS channel can choose between signals from several producers, which is configured in SOURCESEL in PRS\_CHx\_CTRL. Each of these producers outputs one or more signals which can be selected by setting the SIGSEL field in PRS\_CHx\_CTRL. Setting the SOURCESEL bits to 0 (Off) leads to a constant 0 output from the input mux. An overview of the available producers is given in the following table.

Table 13.1. Reflex Producers

Module	Reflex Output	Output Format	Async Support
ACMP	Comparator Output	Level	Yes
ADC	Single Conversion Done	Pulse	_
	Scan Conversion Done	Pulse	_
DAC	Channel 0 Conversion Done	Pulse	_

	Decoder Output	Level/Pulse	Yes
BURTC	Overflow	Pulse	Yes
	Compare match 0	Pulse	Yes

## 13.3.4 Consumers

Consumer peripherals (listed in the following table) can be set to listen to a PRS channel and perform an action based on the signal received on that channel. Most consumers expect pulse input, while some can handle level inputs as well.

Table 13.2. Reflex Consumers

Module	Reflex Input	Input Format	Async Support
ADC	Single Mode Trigger	Pulse	_
	Scan Mode Trigger	Pulse	_
DAC	Channel 0 Trigger	Pulse	_
	Channel 1 Trigger	Pulse	_
TIMER	CC0 Input	Pulse/Level	_
	CC1 Input	Pulse/Level	_
	CC2 Input	Pulse/Level	_
	DTI Fault Source 0 (TIMER0 only)	Pulse	_
	DTI Fault Source 1 (TIMER0 only)	Pulse	_
	DTI Input (TIMER0 only)	Pulse/Level	_
UART	TX/RX Enable	Pulse	_
	RX Input	Pulse/Level	Yes
USART	TX/RX Enable	Pulse	_
	IrDA Encoder Input (USART0 only)	Pulse	
	RX Input	Pulse/Level	Yes

PCNT	S0 input	Level	Yes
	S1 input	Level	Yes
LESENSE	Start scan	Pulse/Level	Yes
	Decoder Bit 0	Level	Yes
	Decoder Bit 1	Level	Yes
	Decoder Bit 2	Level	Yes
	Decoder Bit 3	Level	Yes

**Note:** It is possible to output prs channel 0 - channel 3 onto the GPIO by setting CH0PEN, CH1PEN, CH2PEN, or CH3PEN in the PRS\_ROUTE register.

## 13.3.5 **Example**

The example below (illustrated in the following figure) shows how to set up ADC0 to start single conversions every time TIMER0 over-flows (one HFPERCLK cycle high pulse), using PRS channel 5:

- Set SOURCESEL in PRS CH5 CTRL to 0b011100 to select TIMER0 as input to PRS channel 5.
- Set SIGSEL in PRS CH5 CTRL to 0b001 to select the overflow signal (from TIMER0).
- · Configure ADC0 with the desired conversion set-up.
- Set SINGLEPRSEN in ADC0\_SINGLECTRL to 1 to enable single conversions to be started by a high PRS input signal.
- Set SINGLEPRSSEL in ADC0\_SINGLECTRL to 0x5 to select PRS channel 5 as input to start the single conversion.
- · Start TIMER0 with the desired TOP value, an overflow PRS signal is output automatically on overflow.

Note that the ADC results needs to be fetched either by the CPU or DMA.

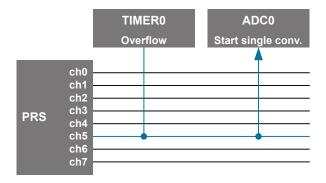

Figure 13.2. TIMER0 Overflow Starting ADC0 Single Conversions Through PRS Channel 5

## 14. EBI - External Bus Interface

## **Quick Facts**

## What?

The EBI is used for accessing external parallel devices. The devices appear as a part of the EFM32WG's internal memory map and are therefore extremely simple to use.

## Why?

Even though the EFM32WG is versatile, there might be a need for specific external devices such as extra RAM, FLASH, LCD, TFT. The EBI simplifies the access to such devices.

#### How?

Through memory mapping the devices appear as a part of the internal memory map. When the processor performs read or writes to the address range of the EBI, the EBI handles the data transfers to and from the external devices. The EBI may be interfaced by the DMA, thus enabling operation in EM1.

#### 14.1 Introduction

The External Bus Interface provides access to external parallel interface devices such as SRAM, FLASH, ADCs and LCDs. The interface is memory mapped into the address bus of the Cortex-M4. This enables seamless access from software without manually manipulating the IO settings each time a read or write is performed. The data and address lines can be multiplexed in order to reduce the number of pins required to interface the external devices. The bus timing is adjustable to meet specifications of the external devices. The interface is limited to asynchronous devices and TFT.

#### 14.2 Features

- · Programmable interface for various memory types
  - · 4 memory bank regions
  - · Individual chip select line (EBI\_CSn) per memory bank
  - · Accurate control of setup, strobe, hold and turn-around timing per memory bank
  - Individual active high / active low setting of interface control signals per memory bank
  - · Slave read/write cycle extension per memory bank
  - · Page mode read
  - NAND Flash support
- Both multiplexed and non-multiplexed address and data line configurations
  - · Up to 28 address lines
  - Up to 16-bit data bus width
- · Automatic translation when AHB transaction width and memory width differ
- · Configurable prefetch from external device
- · Write buffer to limit stalling of the Cortex-M4 or DMA
- TFT Direct Drive
  - · Programmable display and porch sizes
  - Programmable bus timing (frequency, setup and hold timing)
  - · Individual active high / active low setting of interface control signals
  - Frame buffer can be either on-chip or off-chip
  - · Alpha-blending and masking

#### 14.3 Functional Description

An overview of the EBI module is shown in the following figure. The EBI module consists of two submodules. The first submodule implements a generic external device interface to for example SRAM or Flash devices. The second submodule implements a TFT RGB interface which can be used together with the generic external device interface to perform TFT Direct Drive from an external framebuffer to a TFT display.

The EBI has multiplexed and non-multiplexed addressing modes. Fastest operation is achieved when using a non-multiplexed addressing mode. The multiplexed addressing modes are somewhat slower and require an external latch, but they use a significantly lower number of pins. The use of the 16 EBI\_AD pin connections depends on the addressing mode. They are used for both address and data in the multiplexed modes. Also for the non-multiplexed 8-bit address mode both the address and data fit into these 16 EBI\_AD pins. If more address bits or data bits are needed, external latches can be used to support up to 24-bit addresses or 16-bit data in the multiplexed addressing modes using only the 16 EBI\_AD pins. Furthermore, independent of the addressing mode, up to 28 non-multiplexed address lines can be enabled on the EBI\_A pin connections.

When a read operation is requested by the Cortex-M4 or DMA via the EBI's AHB interface, the address is transferred onto the EBI\_AD and/or EBI\_A bus. After a specific number of cycles, the EBI\_REn pin is activated and data is read from the EBI\_AD bus. When a write operation is requested, the address is transferred onto the EBI\_AD and/or EBI\_A bus and subsequently the write data is transferred onto the EBI\_AD bus as the EBI\_WEn pin is activated. The detailed operation in the supported modes is presented in the following sections.

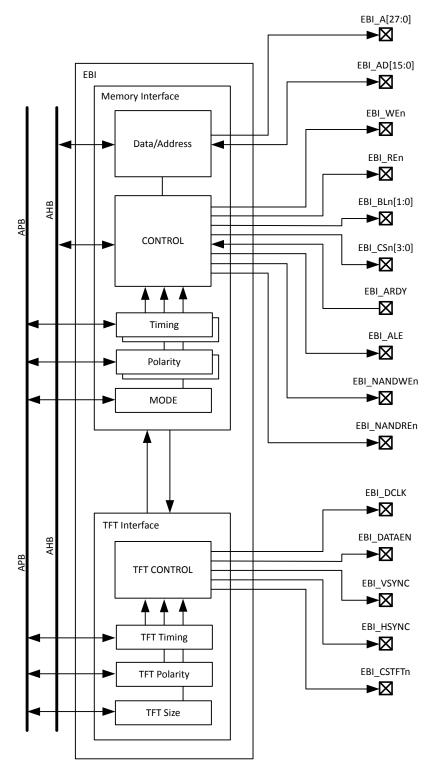

Figure 14.1. EBI Overview

## 14.3.1 Non-Multiplexed 8-Bit Data, 8-Bit Address Mode

In this mode, 8-bit address and 8-bit data is supported. The address is put on the higher 8 bits of the EBI\_AD lines while the data uses the lower 8 bits. This mode is set by programming the MODE field in the EBI\_CTRL register to D8A8. The address space can be extended to 256 MB by using the EBI\_A lines as described in 14.3.6 Extended Addressing. Read and write signals in 8-bit mode are shown in the following figures.

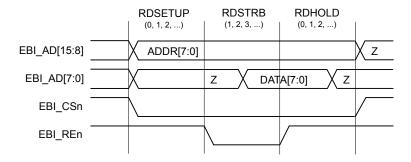

Figure 14.2. EBI Non-multiplexed 8-bit Data, 8-bit Address Read Operation

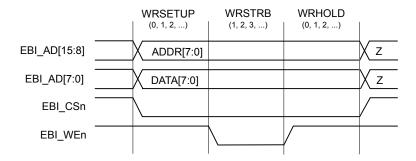

Figure 14.3. EBI Non-multiplexed 8-bit Data, 8-bit Address Write Operation

## 14.3.2 Multiplexed 16-bit Data, 16-bit Address Mode

In this mode, 16-bit address and 16-bit data is supported, but the utilization of an external latch is required. The 16-bit address and 16-bit data bits are multiplexed on the EBI\_AD lines. An illustration of such a setup is shown in the following figure. This mode is set by programming the MODE field in the EBI\_CTRL register to D16A16ALE.

**Note:** In this mode the 16-bit address is organized in 2-byte chunks at memory addresses aligned to 2-byte offsets. Consequently, the LSB of the 16-bit address will always be 0. In order to double the address space, the 16-bit address is internally shifted one bit to the right so that the LSB of the address driven into the EBI\_AD bus, i.e. the EBI\_AD[0]-bit, corresponds to the second least significant bit of the address, i.e. ADDR[1]. At the external device, the LSB of the address must be tied either low or high in order to create a full address.

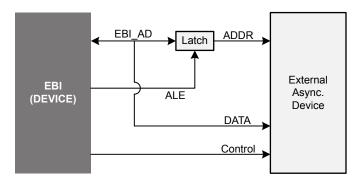

Figure 14.4. EBI Address Latch Setup

At the start of the transaction the address is output on the EBI\_AD lines. The Latch is controlled by the ALE (Address Latch Enable) signal and stores the address. Then the data is read or written according to operation. Read and write signals are shown in the following figures.

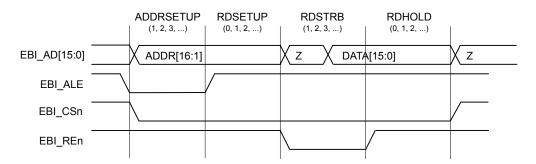

Figure 14.5. EBI Multiplexed 16-Bit Data, 16-Bit Address Read Operation

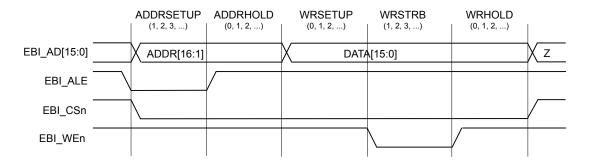

Figure 14.6. EBI Multiplexed 16-Bit Data, 16-Bit Address Write Operation

## 14.3.3 Multiplexed 8-Bit Data, 24-Bit Address Mode

This mode allows 24-bit address with 8-bit data multiplexed on the EBI\_AD lines. The upper 8 bits of the EBI\_AD lines are consecutively used for the highest 8 bits and the lowest 8 bits of the address. The lower 8 bits of the EBI\_AD lines are used for the middle 8 address bits and for data. This mode is set by programming the MODE field in the EBI\_CTRL register to D8A24ALE. Read and write signals are shown in the following figures.

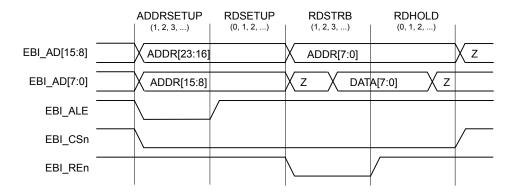

Figure 14.7. EBI Multiplexed 8-Bit Data, 24-Bit Address Read Operation

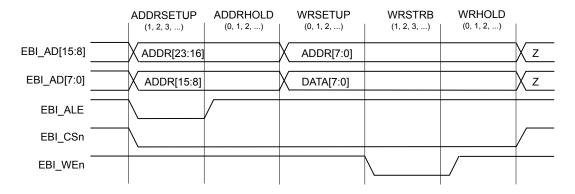

Figure 14.8. EBI Multiplexed 8-Bit Data, 24-Bit Address Write Operation

## 14.3.4 Non-Multiplexed 16-Bit Data, N-Bit Address Mode

In this non-multiplexed mode 16-bit data is driven on the 16 EBI\_AD lines. The addresses are driven on the EBI\_A lines. The address space can be up to 256 MB as described in 14.3.6 Extended Addressing. This mode is set by programming the MODE field in the EBI\_CTRL register to D16. Read and write signals are shown in the following figures for the case in which N address lines on EBI\_A have been enabled.

**Note:** In this mode the 16-bit address is organized in 2-byte chunks at memory addresses aligned to 2-byte offsets. Consequently, the LSB of the 16-bit address will always be 0. In order to double the address space, the 16-bit address is internally shifted one bit to the right so that the LSB of the address driven into the EBI\_A bus, i.e. the EBI\_A[0]-bit, corresponds to the second least significant bit of the address, i.e. ADDR[1]. At the external device, the LSB of the address must be tied either low or high in order to create a full address.

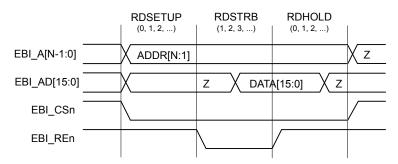

Figure 14.9. EBI Non-Multiplexed 16-Bit Data Read Operation with Extended Address

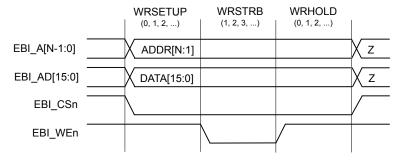

Figure 14.10. EBI Non-Multiplexed 16-Bit Data Write Operation with Extended Address

## 14.3.5 Page Mode Read Operation

Page mode read operation can enhance the performance of a sequence of consecutive asynchronous read transactions by allowing data at subsequent intrapage addresses to be read faster. Page mode operation is enabled by setting the PAGEMODE bitfield in the EBI\_RDTIMING (or EBI\_RDTIMINGn) register to 1. If enabled, the RDPA bitfield in the EBI\_PAGECTRL register defines the duration of an intrapage access and the PAGELEN bitfield in the EBI\_PAGECTRL register defines the number of members in a page. Page mode reads can for example be triggered by consecutive reads resulting from wide AHB reads which are automatically translated into multiple narrow external device reads. Page mode reads can also be triggered by sequential reads resulting from the EBI prefetch unit.

The number of members in a page together with the width of the external device and the INCHIT bit of the EBI\_PAGECTRL register define whether an address change results in an interpage access or in an intrapage access as shown in the following table.

Table 14.1. EBI Intrapage Hit Condition for Read on Address Addr (Non-Mentioned Addr Bits are Unchanged)

PAGELEN, INCHIT	8-bit External Device	16-bit External Device
PAGELEN=MEMBER4, INCHIT=0	Addr[1:0] changed	Addr[2:0] changed
PAGELEN=MEMBER8, INCHIT=0	Addr[2:0] changed	Addr[3:0] changed
PAGELEN=MEMBER16, INCHIT=0	Addr[3:0] changed	Addr[4:0] changed
PAGELEN=MEMBER32, INCHIT=0	Addr[4:0] changed	Addr[5:0] changed
PAGELEN=MEMBER4, INCHIT=1	Addr[1:0] incremented by 1	Addr[2:0] incremented by 2
PAGELEN=MEMBER8, INCHIT=1	Addr[2:0] incremented by 1	Addr[3:0] incremented by 2
PAGELEN=MEMBER16, INCHIT=1	Addr[3:0] incremented by 1	Addr[4:0] incremented by 2
PAGELEN=MEMBER32, INCHIT=1	Addr[4:0] incremented by 1	Addr[5:0] incremented by 2

The initial page mode transaction uses the read setup and read strobe timing as shown in the following figures depending on the used addressing mode. Subsequent transactions are started by changing the low-order address bits and use the page access time defined in the RDPA bitfield of the EBI\_PAGECTRL register. The read hold state RDHOLD is only performed at the end of a page mode read sequence or when bus turn-around occurs. Note that bus turn-around can occur even if only read transactions are performed as the D16A16ALE addressing mode will drive the EBI\_AD lines when programming the external address latch. In this case one bus turn-around RDHOLDX cycle is automatically inserted in between the read and the write action on the EBI\_AD lines. Note that for the D16A16ALE addressing mode the RDPA state immediately follows the ADDRSETUP state, so the HALFALE feature will typically be required to satisfy the external address latch hold requirement. In the D8A24ALE addressing mode there is no need to reprogram the external address latch for intrapage addresses as the external latch then only latches the most significant, non-changed address lines. The following figures show typical page mode read sequences for all addressing modes.

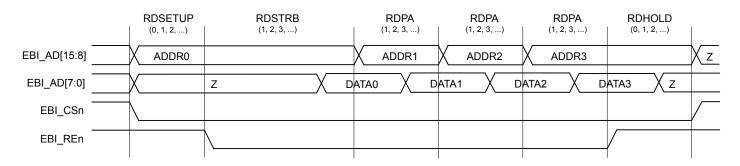

Figure 14.11. EBI Page Mode Read Operation for D8A8 Addressing Mode

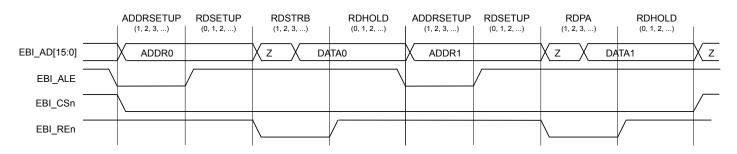

Figure 14.12. EBI Page Mode Read Operation for D16A16ALE Addressing Mode

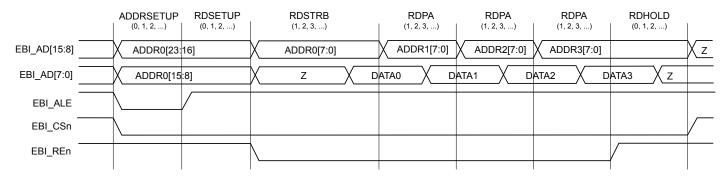

Figure 14.13. EBI Page Mode Read Operation for D8A24ALE Addressing Mode

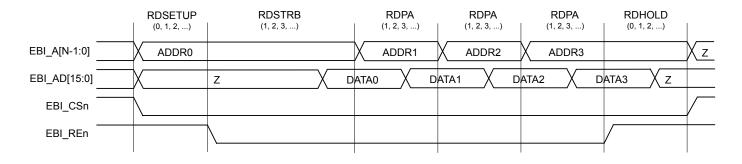

Figure 14.14. EBI Page Mode Read Operation for D16 Addressing Mode

The maximum duration that a page is kept open is defined in the KEEPOPEN bitfield of the EBI\_PAGECTRL register. New read transactions which hit in an open page are started with RDPA intrapage timing if the KEEPOPEN time has not been exceeded at the start of such a transaction. The default setting of KEEPOPEN, which is equal to 0, will therefore never allow for intrapage timing to occur. Transactions are allowed to finish if the KEEPOPEN time is exceeded during the transaction. Otherwise the RDSTRB interpage timing is used for the read transaction. Next to exceeding the KEEPOPEN time there are other reasons for closing an open page. In particular EBI transactions which result in a write or a non-intrapage read always cause the page to be closed. Also the lack of a new EBI transaction will cause an open page to be closed. In order to prevent this last scenario as much as possible read transactions can often be made back to back. This is achieved by enabling prefetching by setting PREFETCH to 1 in the EBI\_RDTIMING (or EBI\_RDTIMINGn) register and by disallowing idle state insertion in between transfers by setting the NOIDLE (or NOIDLEn) bit to 1 in EBI\_CTRL register. The following figure shows an example in which only ADDR1 benefits from intrapage timing because an unrelated AHB transfer not directed at the EBI causes late arrival of ADDR2. ADDR2 arrives too late to be inserted as a back to back read transfer. The page is considered closed and ADDR2 can therefore not benefit from intrapage timing and it results in an interpage access instead.

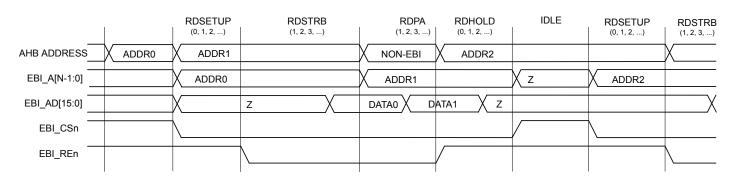

Figure 14.15. EBI Page Closing

## 14.3.6 Extended Addressing

Extended addressing is used to extend the address range for any of the addressing modes described in 14.3.1 Non-Multiplexed 8-Bit Data, 8-Bit Address Mode, 14.3.2 Multiplexed 16-bit Data, 16-bit Address Mode, 14.3.3 Multiplexed 8-Bit Data, 24-Bit Address Mode, and 14.3.4 Non-Multiplexed 16-Bit Data, N-Bit Address Mode. Up to 28 address bits can be individually enabled on the EBI\_A address lines providing up to 256 MB of address space per memory bank. The operation on the EBI\_AD lines is not affected by this. See 14.3.12 Bank Access for the memory map definitions related to the EBI. An example of address extension for the D16 mode is shown in Figure 14.9 EBI Non-Multiplexed 16-Bit Data Read Operation with Extended Address on page 246 and Figure 14.10 EBI Non-Multiplexed 16-Bit Data Write Operation with Extended Address on page 246. A further example for address extension in the multiplexed 16-bit data, 16-bit address mode of 14.3.2 Multiplexed 16-bit Data, 16-bit Address Mode is shown in the following figure. This is achieved by programming the MODE field in the EBI\_CTRL register to D16A16ALE and by enabling the required address lines via the ALB and APEN bitfields of the EBI\_ROUTE register.

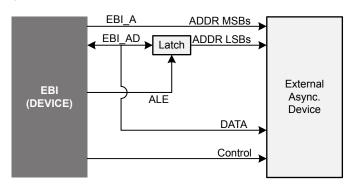

Figure 14.16. EBI Extended Address Latch Setup

Read and write signals for using extended addressing in the D16A16ALE mode are shown in the following figures for the case in which N extra address lines have been enabled. At the start of the transaction the lower address bits are output on the EBI\_AD lines. The Latch is controlled by the ALE (Address Latch Enable) signal and stores the address. Then the data is read or written according to operation. The higher address bits are output on the EBI\_A lines throughout the transfer.

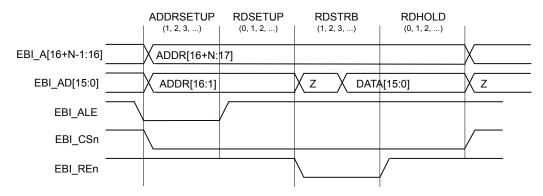

Figure 14.17. EBI 16-Bit Data Multiplexed Read Operation using Extended Addressing

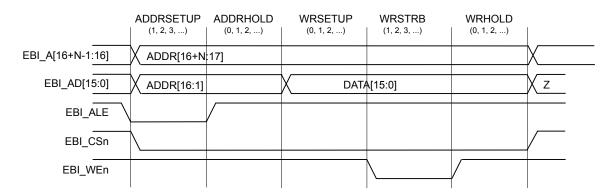

Figure 14.18. EBI 16-Bit Data Multiplexed Write Operation using Extended Addressing

In order to minimize the pin requirements both the lower bound and the upper bound of the enabled EBI\_A lines can be set. This is done in the ALB and APEN bitfields of the EBI\_ROUTE register respectively. For example, in case all memory banks use the 8-bit addressing mode D8A8, then the lower 8 address bits are always output on EBI\_AD. Therefore, if address extension is required, only address bits 8 and upwards need to be enabled on EBI\_A. This is done by setting the EBI\_A lower bound to 8 by setting ALB to A8 in EBI\_ROUTE and by enabling the required higher address lines via the APEN bitfield in EBI\_ROUTE. The operation of the APEN and ALB bitfields is shown in the following table for some typical configurations.

Table 14.2. EBI Enabling EBI\_ADDR Lines for Transaction with Address "Addr" and Data "Data"

Configuration	Addresses on EBI_A	Addresses/data on EBI_AD
MODE = D8A8, ALB = A8, APEN = A28	EBI_A[27:8] = Addr[27:8]	EBI_AD[15:0] = {Addr[7:0], Data[7:0]}
MODE = D16A16ALE, ALB = A16, APEN = A27	EBI_A[26:16] = Addr[27:17]	EBI_AD[15:0] = Addr[16:1]; Data[15:0]
MODE = D8A24ALE, ALB = A24, APEN = A28	EBI_A[27:24] = Addr[27:24]	EBI_AD[15:0] = Addr[23:8]; {Addr[7:0], Da- ta[7:0]}
MODE = D16, ALB = A0, APEN = A27	EBI_A[26:0] = Addr[27:1]	EBI_AD[15:0] = Data[15:0]

## 14.3.7 Prefetch Unit and Write Buffer

Prefetching from external memory can enhance the performance of a sequence of consecutive transfers. In particular sequential code execution from external memory can benefit from prefetch. Also prefetch will typically lead to better utilization of intrapage accesses in case page mode is used. If prefetch is enabled, the prefetch unit will sequentially prefetch one data item of the same width as the last Cortex-M4 or DMA read transaction handled by the EBI. Note that one prefetch transaction might lead to multiple external device transactions as described in Table 14.3 EBI Mapping of AHB Transactions to External Device Transactions on page 255. Prefetch is not performed in reaction to write transactions, nor will prefetch cross bank boundaries. The prefetch unit is enabled via the PREFETCH bitfield in the EBI\_RDTIMING and EBI\_RDTIMINGn registers. When the ITS bitfield in the EBI\_CTRL register is set to 0, the PREFETCH bitfield from EBI\_RDTIMING applies to all 4 memory banks. When ITS is set to 1 the prefetch unit can be individually enabled per bank. In this case register EBI\_RDTIMING only applies to bank 0. Prefetch enabling for bank n is then defined in the EBI\_RDTIMINGn register.

The EBI has a 1 entry 32-bit wide write buffer. The write buffer can be used to limit stalling by partially decoupling the Cortex-M4 or DMA from a potentially slow external device. Only writes which are guaranteed to not cause an error (e.g. timeout) in the EBI will be buffered when the write buffer is enabled, such that precise error generation is guaranteed. The write buffer is disabled via the WBUF-DIS bitfield in the EBI\_WRTIMING and EBI\_WRTIMINGn registers. When the ITS bitfield in the EBI\_CTRL register is set to 0, the WBUF-DIS bitfield from EBI\_WRTIMING applies to all 4 memory banks. When ITS is set to 1 the write buffer can be individually disabled per bank. In this case register EBI\_WRTIMING only applies to bank 0. Write buffer disabling for bank n is then defined in the EBI\_WRTIMINGn register.

The AHBACT status bit in the EBI\_STATUS register indicates whether an AHB transaction is still active in the EBI or not. When performing an AHB write, the AHBACT bit stays 1 until the required transaction(s) with the external device have finished, independent of whether the AHB write gets buffered or not. On an AHB read with prefetching enabled, AHBACT stays high until the potential external device prefetch transaction(s) have finished.

## 14.3.8 Strobe Length

For external devices with low, but non-zero, setup requirements the performance overhead for EBI transactions can be relatively large if a full cycle setup time needs to be used. It is possible to borrow half of the cycle time from a neighboring strobe phase in order to define setup times with a granularity of half the internal clock period.

The durations of the EBI\_ALE, EBI\_REN, EBI\_WEN, EBI\_NANDREN and EBI\_NANDWEN strobes can be individually decreased by half the internal clock period via the HALFALE, HALFRE and HALFWE bitfields in the address timing, read timing and write timing registers respectively. In case of EBI\_ALE the trailing edge of the strobe can be moved half a clock period earlier. In case of EBI\_REN, EBI\_WEN, EBI\_NANDREN and EBI\_NANDWEN the leading edge of the strobe can be moved half a clock period later. Decreasing the length of the EBI\_ALE strobe can be thought of as increasing the length of the RDSETUP phase by the same amount. Similarly, decreasing the length of the EBI\_REN, EBI\_WEN, EBI\_NANDREN, EBI\_NANDWEN strobes can be thought of as increasing the length of the RDSETUP and WRSETUP phases. Note that the length of the ADDRSETUP, RDSTRB, and WRSTRB phases is still 1 or more internal clock cycles. For example, when HALFRE is set to 1 and RDSTRB is programmed to 2, the length of the RDSTRB phase is 2 cycles. The duration of the EBI\_REN pulse is however decreased by half a cycle to 1 1/2 cycles.

The following figures show read and write transactions in the multiplexed 16-bit address, 16-bit data mode in which half strobes are enabled for EBI ALE, EBI REn and EBI WEn.

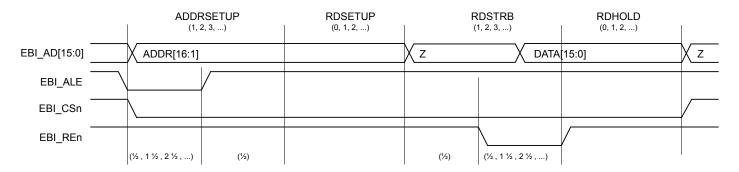

Figure 14.19. EBI Multiplexed Read Operation with Reduced Length Strobes

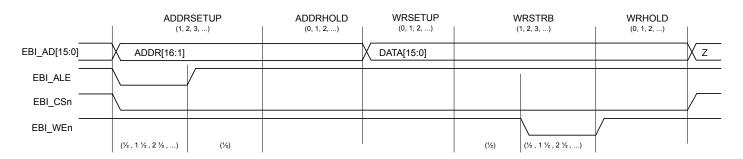

Figure 14.20. EBI Multiplexed Write Operation with Reduced Length Strobes

### 14.3.9 Bus Turn-Around and Idle Cycles

The EBI\_AD lines can be driven by either the EFM32WG or by the external device. Depending on the characteristics of an external device, the RDHOLD should be programmed to ensure adequate bus turnaround time. Default the EBI inserts an initial IDLE cycle, during which the EBI does not drive the EBI\_AD lines, after each external transaction. Furthermore, the EBI deasserts the EBI\_CSn, EBI\_REn, and EBI\_WEn lines during IDLE cycles. In case of subsequent IDLE cycles, after the initial one, the EBI will drive the EBI\_AD lines while keeping the EBI\_CSn, EBI\_REn, and EBI\_WEn lines deasserted. The IDLE state insertion is shown for two back-to-back read transactions in the first following figure. In case that the IDLE state provides the required bus turn-around time, the RDHOLD parameter can be programmed to 0. For increased performance, the automatic IDLE state insertion can be prevented by setting the NOI-DLE/NOIDLEn bits in the EBI\_CTRL register to 1. This scenario is shown in the second following figure for two back-to-back reads in a non-multiplexed addressing mode. Note that in case RDSETUP and RDHOLD are both programmed to 0, then the EBI\_REn line will not be deasserted between back-to-back read transfers. The same will happen for non-multiplexed back-to-back write transactions with WRSETUP and WRHOLD both programmed to 0. In case that NOIDLE/NOIDLEn is 1 and a read is immediately followed by a write on the EBI\_AD lines, one bus turn-around cycle called RDHOLDX is automatically inserted in between the read and the write action. During a RDHOLDX cycle the external EBI signals are driven in the same way as during regular RDHOLD cycles, i.e. the EBI\_REn line will get deasserted while the EBI\_CSn line will stay asserted.

An IDLE cycle will automatically get inserted for the following cases:

- Between two external device transactions in case the NOIDLE/NOIDLEn bit is 0.
- Between two external device transactions to different banks.
- · When no request for an external transaction is available in the EBI.

A RDHOLDX cycle will automatically get inserted for the following case:

Between a read and a subsequent write on the EBI\_AD lines. Note that this is only possible if NOIDLE/ NOIDLEn is set to 1. Also
note that a read in a multiplexed addressing mode (e.g. D16A16ALE) starts with a write on the EBI\_AD lines when it is in the ADDRSETUP state.

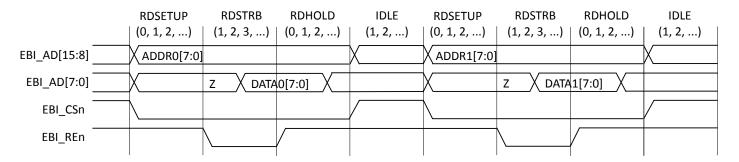

Figure 14.21. EBI Enforced IDLE Cycles between Transactions

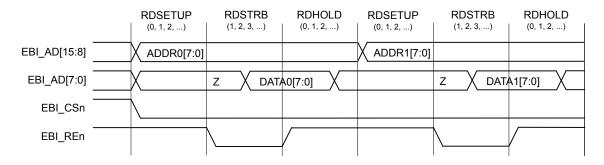

Figure 14.22. EBI No Enforced IDLE Cycles between Transactions

**Note:** In case NOIDLE/NOIDLEn bits are set in EBI\_CTRL the read or write strobes can remain asserted for back-to-back transfers if no further separation is guaranteed via for example RDSETUP, RDHOLD, WRSETUP, or WRHOLD bitfields.

## 14.3.10 Timing

The duration of the states in the transaction is defined by the corresponding uppercase name above the state, e.g. the address setup state in Figure 14.8 EBI Multiplexed 8-Bit Data, 24-Bit Address Write Operation on page 245 is active for a number of internal clock cycles defined by ADDRSET bitfield in the EBI\_ADDRTIMING register. Similar timing can be defined by the RDSTRB bitfield in the EBI\_RDTIMING register and WRSTRB in the EBI\_WRTIMING register. These parameters all have a minimum duration of 1 cycle, which is set by HW in case the bitfield is programmed to 0.

The setup and hold timing parameters are ADDRHOLD in the EBI\_ADDRTIMING register, RDHOLD and RDSETUP in the EBI\_RDTIMING register and WRHOLD and WR SETUP in the EBI\_WRTIMING register. Writing a value m to one of these bitfields results in a duration of the corresponding state of m cycles. If these parameters are set to 0, it effectively means that the state is skipped.

Page mode access time is defined in the RDPA bitfield of the EBI\_PAGECTRL register. This parameters has a minimum duration of 1 cycle, which is set by HW in case the bitfield is programmed to 0.

When the ITS bitfield in the EBI\_CTRL register is set to 0, the timing set defined in the EBI\_ADDRTIMING, EBI\_RDTIMING and EBI\_WRTIMING registers applies to all 4 memory banks. When ITS is set to 1 each memory bank uses an individual timing set. In this case registers EBI\_ADDRTIMING, EBI\_RDTIMING and EBI\_WRTIMING only apply to bank 0. Timing for bank n is then defined in the EBI\_ADDRTIMINGn, EBI\_RDTIMINGn and EBI\_WRTIMINGn registers.

**Note:** All timing related bitfields have a default value which is equal to the highest possible value for these bitfields, which makes the default values a better fit for slow memory devices. This differs from the EFM32G devices in which the default values correspond to the lowest possible values, which would only be appropriate for fast memory devices.

#### 14.3.11 Data Access Width

The mapping of AHB transactions to external device accesses depends on the data width of the external device and on whether or not it supports byte lanes. The data width of external devices is specified in the MODE and MODEn bitfields of the EBI\_CTRL register. An external device is specified to be either 8-bit or 16-bit wide. Availability of byte lane support by the external device is specified via the BL and BLn bitfields of the EBI\_CTRL register. When the ITS bitfield in the EBI\_CTRL register is set to 0, the MODE and BL bitfields apply to all 4 memory banks. When ITS is set to 1 each memory bank uses an individual mode and byte lane enable definition. In this case bitfields MODE and BL only apply to bank 0. The mode and byte lane availability for bank n is then defined in the MODEn and BLn bitfields.

In case the AHB transaction width does not match the width of the selected device, the EBI automatically translates the AHB transaction into 1 or more external device transactions matching the capabilities of that device. If one AHB transaction is translated into multiple external transactions, then the external transactions have incrementing addresses and start with the lowest data byte(s) from the AHB transaction. The translation, and possibly bus fault generation, is explained below and in the following table:

- If the AHB transaction width is larger than the external device width, then multiple consecutive external transactions are performed starting with the least significant data.
- If the AHB transaction width is smaller than the external device width, then EBI behavior depends on whether or not byte lanes are available for the selected device. Reads either use byte lane support when available, or read according to the full external device width and disregard the superfluous data. Writes normally either use byte lane support when available, or perform a read-modify-write sequence to only change the required data. However, NAND Flash does not support byte lanes or random access read-modify-write and therefore a hard fault is generated in case of an 8-bit write to a bank designated as 16-bit NAND bank.

Table 14.3. EBI Mapping of AHB Transactions to External Device Transactions

Data Access by Cortex- M4, DMA, or prefetch	8-bit External Device (non- NAND) transaction(s)	16-bit External Device (non- NAND) transaction(s) (with byte lanes)	16-bit External Device (non- NAND) transaction(s) (without byte lanes)	8-bit NAND Flash transaction(s)	16-bit NAND Flash transaction(s)
8-bit read	1 x 8-bit read	1 x 8-bit read (using byte lane)	1 x 16-bit read	1 x 8-bit read	1 x 16-bit read
16-bit read	2 x 8-bit read	1 x 16-bit read	1 x 16-bit read	2 x 8-bit read	1 x 16-bit read
32-bit read	4 x 8-bit read	2 x 16-bit read	2 x 16-bit read	4 x 8-bit read	2 x 16-bit read
8-bit write	1 x 8-bit write	1 x 8-bit write (using byte lane)	1 x 16-bit read; 1 x 16-bit write (read- modify-write)	1 x 8-bit write	- (Hard fault)
16-bit write	2 x 8-bit write	1 x 16-bit write	1 x 16-bit write	2 x 8-bit write	1 x 16-bit write
32-bit write	4 x 8-bit write	2 x 16-bit write	2 x 16-bit write	4 x 8-bit write	2 x 16-bit write

## 14.3.12 Bank Access

The EBI is split in 4 different address regions, each connected to an individual EBI\_CSn line. When accessing one of the memory regions, the corresponding CSn line is asserted. This way up to 4 separate devices can share the EBI lines and be identified by the EBI CSn line. Each bank can individually be enabled or disabled in the EBI CTRL register.

The bank separation depends on whether the access originates from code space or not and on the setting of the ALTMAP bit in the EBI\_CTRL register. From code space three 32 MB banks and one 128 MB bank can be accessed. From data space either four 64 MB banks (when ALTMAP bit is 0) or four 256 MB banks (when the ALTMAP bit is 1) can be accessed as shown in the following figures.

The EBI regions starting at address 0x80000000 in the memory map of the EFM32WG can also be used for code execution. When running code via EBI regions starting at this address, the Cortex-M4 uses the System bus interface to fetch instructions. This results in reduced performance as the Cortex-M4 accesses stack, other data in SRAM and peripherals using the System bus interface. Code accesses via the System bus interface will not be cached. Furthermore, it should be noted that the address area from 0xA0000000 to 0xC0000000 is marked NX (no-execute) by default. To be able to run code via the EBI efficiently, the EBI is also mapped in the code space at address 0x12000000. When running code from this space, the Cortex-M4 fetches instructions through the I/D-Code bus interface, leaving the System bus interface for data access. Instructions fetched via the I/D-Code bus interface can be cached to increase performance. The EBI regions mapped into the code space can however only be accessed by the CPU, i.e. not the DMA.

Depending on the setting of the ITS bitfield in the EBI\_CTRL register. The external device behavior, including for example data width, timing definitions, page mode operation, and pin polarities, is either defined for all banks at once or individually per bank.

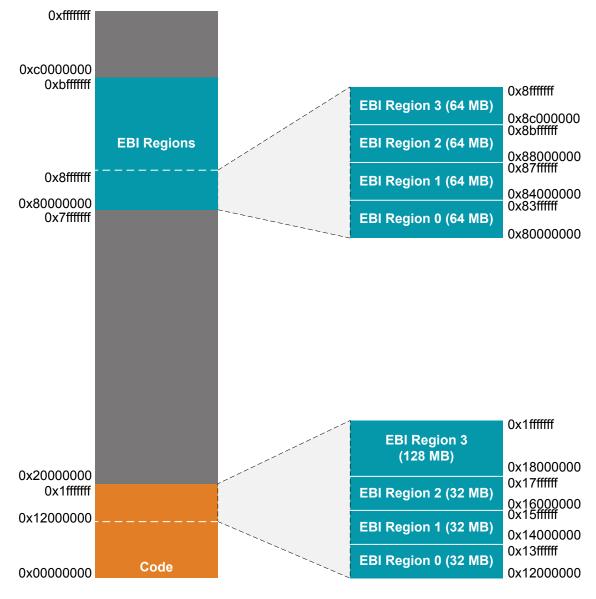

Figure 14.23. EBI Default Memory Map (ALTMAP = 0)

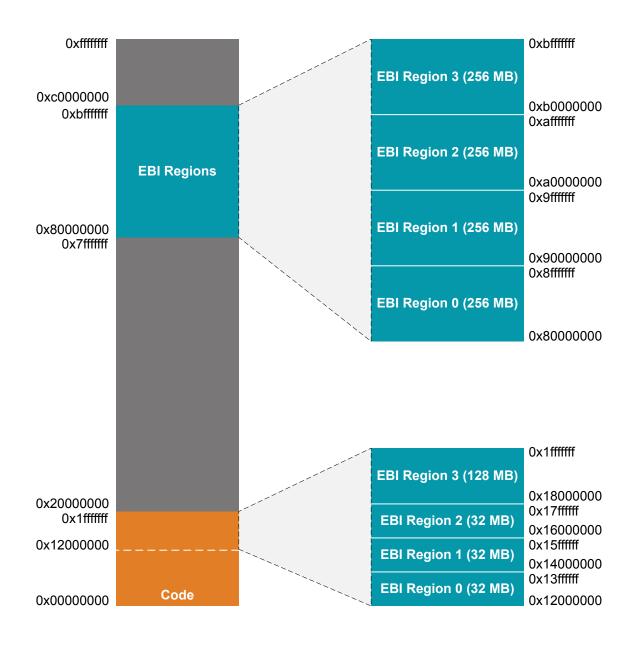

Figure 14.24. EBI Alternative Memory Map (ALTMAP = 1)

## 14.3.13 WAIT/ARDY

Some external devices are able to indicate that they are not finished with either write or read operation by asserting the WAIT / ARDY line. This input signal is used to extend the REn/WEn cycles for slow devices. The interpretation of the polarity of this signal can be configured with the ARDYPOL bit in EBI\_POLARITY. E.g. if the ARDYPOL is set to ACTIVELOW, then the REn/WEn cycle is extended while the ARDY line is kept low. The ARDY functionality is enabled by setting the ARDYEN bit in the EBI\_CTRL register. It is also possible to enable a timeout check, which generates a bus error if the ARDY is not deasserted within the timeout period. This prevents a system lock up condition in the case that the external device does not deassert ARDY. The timeout functionality is disabled by setting ARDYTODIS in the EBI\_CTRL register.

When the ITS bitfield in the EBI\_CTRL register is set to 0, the wait behavior defined in the ARDYEN and ARDYTODIS bitfields applies to all 4 memory banks. When ITS is set to 1 each memory bank uses an individual wait behavior definition. In this case bitfields ARDYEN and ARDYTODIS only apply to bank 0. Wait behavior for bank n is then defined in the ARDYNEN and ARDYTONDIS bitfields.

#### 14.3.14 NAND Flash Support

NAND Flash devices offer high density at relatively low cost when compared to NOR Flash devices. Unlike NOR Flash, which offers random read access, NAND Flash devices are based on page access and use an indirect interface. Furthermore, a NAND Flash can contain invalid bits leading to invalid blocks, which leads to requirements such as bit error detection/correction and bad block management.

The EBI offers support for glueless connection of a NAND Flash by implementing dedicated EBI\_NANDREn and EBI\_NANDWEn pins and by providing hardware for single error correction double error detection (SEC-DED) Error Correction Code (ECC) generation. NAND Flash support is enabled by setting the EN bitfield in the EBI\_NANDCTRL register to 1. The BANKSEL bitfield in EBI\_NANDCTRL defines which memory bank has a NAND Flash devices attached to it. NAND Flash data width, read timing, and write timing are programmed via the standard EBI registers as described in 14.3.14.2 Width and Timing Configuration. ECC support is described in Section 14.3.15 Error Correction Code.

Both standard and Chip Enable Don't Care (CEDC) NAND Flash devices are supported and they can be attached as shown in the following figures. For standard NAND Flash devices, the Chip Enable (CEn) pin needs to remain asserted low during the entire read cycle busy period, in which data is transferred from the memory array into the NAND Flash internal data registers in order to prevent an early return to standby mode. CEDC NAND Flash devices do not have this restriction, but they do not support the automatic sequential read function. For CEDC NAND Flash the shared EBI\_REn and EBI\_WEn pins can be used instead of the dedicated EBI\_NANDREn and EBI\_NANDWEn pins.

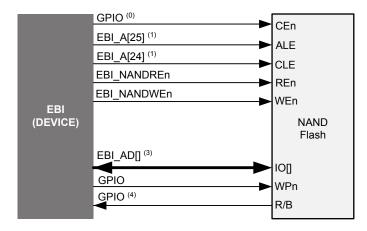

Figure 14.25. EBI Connection with Standard NAND Flash

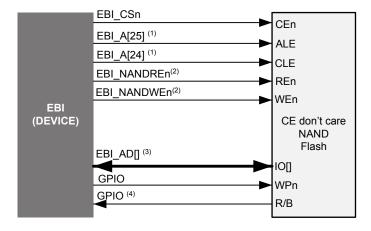

Figure 14.26. EBI Connection with Chip Enable Don't Care NAND Flash

#### Note:

- (0) For a standard NAND Flash the EBI\_CSn should be left unconnected
- (1) The address lines mapping to the NAND Flash ALE and CLE signals can be chosen as explained in 14.3.14.1 Register Selection
- (2) For a CEDC NAND Flash the shared EBI\_REn and EBI\_WEn pins can be used instead of the dedicated EBI\_NANDREn and EBI\_NANDWEn pins
- (3) Both 8-bit and 16-bit NAND Flash are supported.
- (4) The NAND Flash ready/busy (R/B) signal should be observed via GPIO (not via EBI\_ARDY)

#### 14.3.14.1 Register Selection

NAND Flash uses an indirect I/O interface in which the NAND Flash is controlled by programming the NAND Flash internal Command, Address, and Data registers. NAND Flash does not use dedicated address lines. Because of this indirect I/O interface the NAND Flash memory size is not restricted by the memory map of the EFM32WG. The NAND Command, Address, and Data registers can be accessed via memory mapped IO in which two address lines are chosen for connection with the ALE and CLE signals. The memory mapping and the two used address lines should be chosen such that they adhere to the ALE/CLE encoding shown in the following table. Either EBI\_A or EBI\_AD address lines can be used as long as the chosen addressing mode does not multiplex data signals onto the chosen lines. The EBI\_A[25:24] address lines used in Figure 14.25 EBI Connection with Standard NAND Flash on page 258 and Figure 14.26 EBI Connection with Chip Enable Don't Care NAND Flash on page 258 are just an example.

Table 14.4. EBI NAND Flash Register Select

ALE	CLE	Selected NAND Flash Register
0	0	Data Register
0	1	Command Register
1	0	Address Register
1	1	Undefined

## 14.3.14.2 Width and Timing Configuration

The regular EBI registers are used for defining transfer width, read timing, and write timing for the transactions on the NAND Flash interface. NAND Flash specific parameters as for example block size or the number of address cycles are not configured in the EBI and need to be dealt with via driver software. Also higher level tasks as for example wear-leveling, bad block management, and logical-to-physical block mapping should be addressed via driver software.

External transaction width is defined via the address mode as defined in MODE field of EBI\_CTRL. As only 3 NAND Flash registers are memory mapped it suffices to use either the D8A8 or D16 address mode. The D16A16ALE and D8A24ALE address modes can also be used, but they require unnecessary external address latch cycles and/or circuitry. For a 8-bit wide NAND Flash device, the D8A8 address mode is therefore recommended, whereas for a 16-bit wide NAND Flash device the D16 address mode is recommended. If the AHB transaction width does not match the external NAND device transaction width, then automatic transaction translation is performed as described in 14.3.11 Data Access Width. Note that a bus fault is generated in case of an 8-bit write to a 16-bit NAND device as neither byte lanes nor read-modify-write is supported for NAND Flash.

NAND Flash write timing is defined in the EBI\_WRTIMING(n) register. The following figures show the command latch, address latch and data input timing respectively assuming the D8A8 address mode with EBI\_AD[x] used as ALE and EBI\_AD[y] used as CLE.

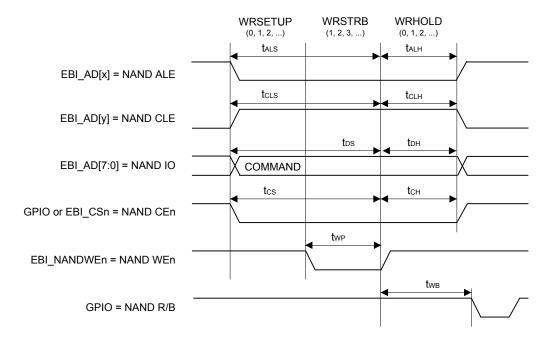

Figure 14.27. EBI NAND Flash Command Latch Timing

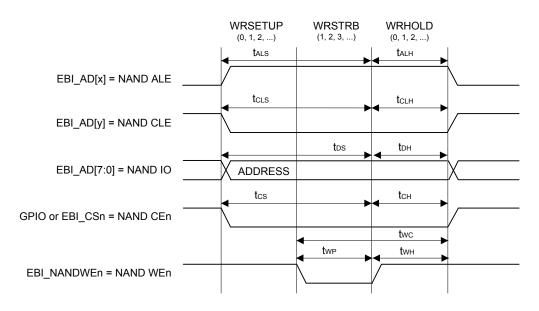

Figure 14.28. EBI NAND Flash Address Latch Timing

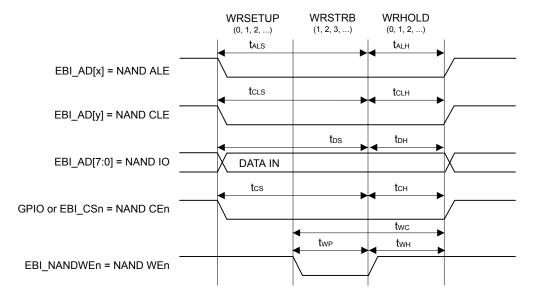

Figure 14.29. EBI NAND Flash Data Input Timing

The EBI\_WRTIMING(n) setting requirements for satisfying the NAND Flash timing parameters for command latching, address latching and data input timing are shown in the following table.

Table 14.5. EBI NAND Flash Write Timing

NAND Flash Write Timing Parameter	EBI Write Timing Parameter Requirements
tADL	<= t(WRHOLD) + t(WRSETUP) + t(WRSTRB)
tALS	<= t(WRSETUP) + t(WRSTRB)
tCS	<= t(WRSETUP) + t(WRSTRB)
tCLS	<= t(WRSETUP) + t(WRSTRB)
tDS	<= t(WRSETUP) + t(WRSTRB)

NAND Flash Write Timing Parameter	EBI Write Timing Parameter Requirements
tALH	<= t(WRHOLD)
tCH	<= t(WRHOLD)
tCLH	<= t(WRHOLD)
tDH	<= t(WRHOLD)
tWC	<= t(WRHOLD) + t(WRSETUP) + t(WRSTRB)
tWH	<= t(WRHOLD) + t(WRSETUP)
tWP	<= t(WRSTRB)
tWB	(R/B edges can be detected by edge triggered GPIO interrupts)

NAND Flash read timing is defined in the EBI\_RDTIMING(n) register. The following figure shows the NAND Flash data output timing assuming the D8A8 address mode.

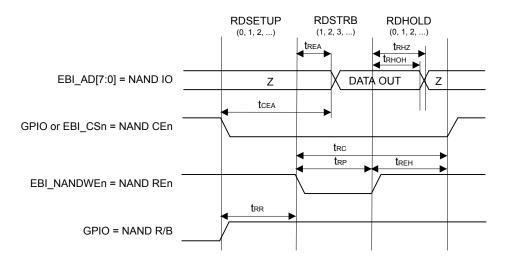

Figure 14.30. EBI NAND Flash Data Output Timing

The EBI\_RDTIMING(n) setting requirements for satisfying the NAND Flash timing parameters for data output timing are shown in the following table.

Table 14.6. EBI NAND Flash Read Timing

NAND Read Timing Parameter	EBI Read Timing Parameter Requirements
tCEA	<= t(RDSETUP) + t(RDSTRB)
tREA	<= t(RDSTRB)
tRP	<= t(RDSTRB)
tRHZ	<= t(RDHOLD)
tREH	<= t(RDHOLD) + t(RDSETUP)
tRC	<= t(RDHOLD) + t(RDSETUP) + t(RDSTRB)
tRR	<= t(RDSETUP) (assuming software wait for R/B high)
tAR	<= t(RDSETUP)
tCLR	<= t(RDSETUP)
tIR	<= t(RDSETUP)

The NAND Flash timing parameters tWHR and tRHW define separation of read and write pulses and therefore they can be satisfied by a combination of EBI\_RDTIMING(n) and EBI\_WRTIMING(n) settings as shown in the following table.

Table 14.7. EBI NAND Flash Read/Write Timing Requirements

NAND Timing Parameter	EBI Timing Parameter
tWHR	<= t(WRHOLD) + t(RDSETUP)
tRHW	<= t(RDHOLD) + t(WRSETUP)

Remaining NAND Flash timing parameters, e.g. tRST and tPROG, should be dealt with in software.

#### 14.3.14.3 Application Examples

A typical 528-byte page read sequence for an 8-bit wide NAND Flash is as follows:

- Configuration: Enable and select the memory bank connected to the NAND Flash device via the EN and BANKSEL bitfields in the EBI\_NANDCTRL register. Set the MODE field of the EBI\_CTRL register to D8A8 indicating that the attached device is 8-bit wide. Program the EBI\_RDTIMING and EBI\_WRTIMING registers to fulfill the NAND timing requirements.
- Command and address phase: Program the NAND Command register to the page read command and program the NAND Address register to the required read address. This can be done via Cortex- M4 or DMA writes to the memory mapped NAND Command and Address registers. The automatic data access width conversions described in 14.3.11 Data Access Width can be used if desired to for example automatically perform 4 consecutive address byte transactions in response to one 32-bit word AHB write to the NAND Address register (in this case the 2 address LSBs should not be used to map onto the NAND ALE/CLE signals).
- Data transfer phase: Wait for the NAND Flash internal data transfer phase to complete as indicated via its ready/busy (R/B) pin. The user can use the GPIO interrupt functionality for this. The 528-byte data is now ready for sequential transfer from the NAND Flash Data register.
- Read phase: Clear the ECC\_PARITY register and start Error Code Correction (ECC) parity generation by setting both the ECC-START and ECCCLEAR bitfields in the EBI\_CMD register to 1. Now all subsequently transferred data to/from the NAND Flash devices is used to generate the ECC parity code into the EBI\_ECCPARITY register. Read 512 subsequent bytes of main area data from the NAND Flash Data register via DMA transfers. This can for example be done via 32-bit word DMA transfers (as long as the two address LSBs are not used to map onto the NAND ALE/CLE signals). Stop ECC parity generation by setting the ECCSTOP bitfield in the EBI\_CMD register to 1 so that following transactions will not modify the parity result. Read out the final 16 bytes from the NAND Flash spare data area.
- Error correction phase: Compare the ECC code contained in the read spare area data against the computed ECC code from the EBI\_ECCPARITY register. The user software can accept, correct, or discard the read data according the comparison result. No automatic correction is performed.

A typical 528-byte page program sequence for an 8-bit wide NAND Flash is as follows:

- Configuration: Configure the EBI for NAND Flash support via the EBI\_NANDCTRL, EBI\_CTRL, EBI\_RDTIMING and EBI\_WRTIM-ING registers.
- Command and address phase: Program the NAND Command register to command for page programming (serial data input) and program the NAND Address register to the desired write address.
- Write phase: Clear the ECC\_PARITY register and start Error Code Correction (ECC) parity generation by setting both the ECC-START and ECCCLEAR bitfields in the EBI\_CMD register to 1. Now all subsequently transferred data to/from the NAND Flash devices is used to generate the ECC parity code into the EBI\_ECCPARITY register. Write 512 subsequent bytes of user main data to the NAND Flash Data register via for example DMA transfers. Stop ECC parity generation and read out the computed ECC parity data from EBI\_ECCPARITY. Write the final 16 bytes of spare data including the computed ECC parity data bytes.
- Program phase: Write the auto program command to the NAND Flash Command register after which the NAND Flash will indicate
  that it is busy via its read/busy (R/B) pin. After read/busy goes high again, the success of the program command can be verified by
  programming the read status command.

#### 14.3.15 Error Correction Code

The EBI provides provides hardware support for generation of an Error Correction Code (ECC). The used ECC is a Hamming (Hsiao) code providing single bit error correction and double error detection (SECDED). ECC can be used to detect and/or correct failing bits in a NAND Flash page. ECC generation is enabled by setting bitfield ECCSTART in the EBI\_CMD register to 1. All subsequent data traffic to/from the memory bank specified in the BANKSEL bitfield of the EBI\_NANDCTRL register is then used for generation of the ECC into the EBI\_ECCPARITY register independent of the address in that bank. ECC generation is stopped by writing 1 to the ECCSTOP bitfield in the EBI\_CMD register. The EBI\_ECCPARITY register is cleared by writing 1 to the ECCCLEAR register. The ECCACT status bit in the EBI\_STATUS register shows whether ECC generation is active or not.

The ECC computation is as shown in the following figure and table. Although the table only shows the ECC generation for 8-bit data transfers, the ECC hardware also works for 16-bit data transfers. In that case only the interpretation of the parity bits is different.

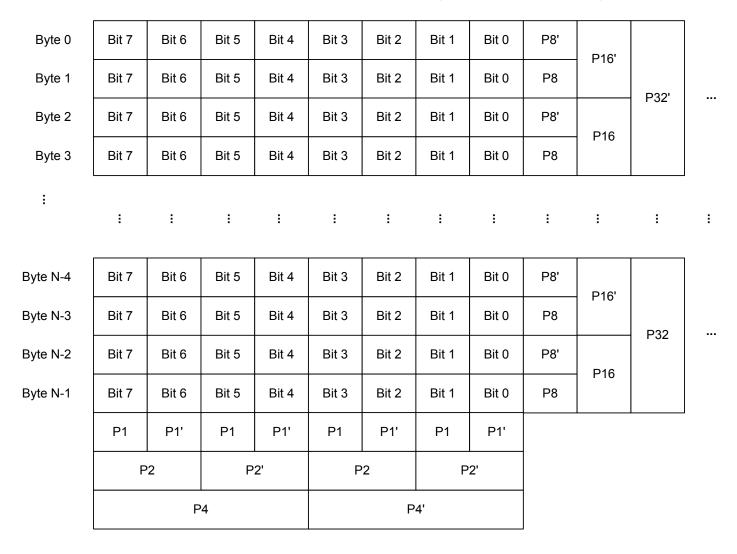

Figure 14.31. EBI ECC Generation

Table 14.8. EBI ECC Bit/Column Parity

Parity Bit	Generation for 8-Bit Data
P1'	Bit 6 xor Bit 4 xor Bit 2 xor Bit 0 xor P1'
P1	Bit 7 xor Bit 5 xor Bit 3 xor Bit 1 xor P1
P2'	Bit 5 xor Bit 4 xor Bit 1 xor Bit 0 xor P2'
P2	Bit 7 xor Bit 6 xor Bit 3 xor Bit 2 xor P2

Parity Bit	Generation for 8-Bit Data
P4'	Bit 3 xor Bit 2 xor Bit 1 xor Bit 0 xor P4'
P4	Bit 7 xor Bit 6 xor Bit 5 xor Bit 4 xor P4

Table 14.9. EBI ECC Byte/Row Parity

Parity Bit	Generation for 8-Bit Data
RP(x)	Byte(x)(7) xor Byte(x)(6) xor Byte(x)(5) xor Byte(x)(4) xor Byte(x) (3) xor Byte(x)(2) xor Byte(x)(1) xor Byte(x)(0)
P8'	RP(0) xor RP(2) xor RP(4) xor RP(6) xor xor RP(N-4) xor RP(N-2)
P8	RP(1) xor RP(3) xor RP(5) xor RP(7) xor xor RP(N-3)xor RP(N-1)
P16'	RP(0) xor RP(1) xor RP(4) xor RP(5) xor xor RP(N-4) xor RP(N-3)
P16	RP(2) xor RP(3) xor RP(6) xor RP(7) xor xor RP(N-2) xor RP(N-1)

The generated ECC code can be read from the EBI\_ECCPARITY register according to the format shown in the following figure. The number of valid ECC bits depends on the number of transferred bytes during the time that the ECC hardware is running as indicated in the following table.

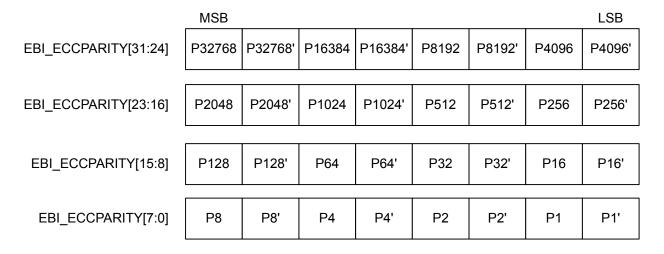

Figure 14.32. EBI EBI\_ECCPARITY Format

Table 14.10. EBI EBI\_ECCPARITY Calid Bits

Number of Data Bytes Used for ECC Generation	Valid EBI_ECCPARITY Bits
256	EBI_ECCPARITY[21:0]
512	EBI_ECCPARITY[23:0]
1024	EBI_ECCPARITY[25:0]
2048	EBI_ECCPARITY[27:0]

Number of Data Bytes Used for ECC Generation	Valid EBI_ECCPARITY Bits
4096	EBI_ECCPARITY[29:0]
8192	EBI_ECCPARITY[31:0]

Software can compare, XOR, the parity data generated in EBI\_ECCPARITY with the parity information stored in the spare area for the used data set. The syndrome resulting from XOR'ing the valid EBI\_ECCPARITY bits with the ECC code read from the spare area can be used for error detection and correction as shown in the following table.

Table 14.11. EBI Error Detection Result

Error Detection Result	Syndrome	Interpretation
No Error	Syndrome has all valid Pn, Pn' bits 0	No error has been detected
1-bit Correctable Error	For all valid syndrome (Pn, Pn') pairs: Pn = not(Pn')	1 bit in the user main data is incorrect and it can be corrected. For 8-bit wide data the position of the incorrect bit is indicated by bit pattern (P4, P2, P1); the position of the incorrect byte is indicated by (, P32, P16, P8). For 16-bit wide data the position of the incorrect bit is (P8, P4, P2, P1); the incorrect byte number is indicated by (, P64, P32, P16)
ECC Error	1 bit of the XOR result is high	An error has been detected in the ECC itself. No error has been detected in the user data
Uncorrectable Error	Other cases	Multiple (2 or more) bits are incorrect. This error cannot be corrected

#### 14.3.16 TFT Direct Drive

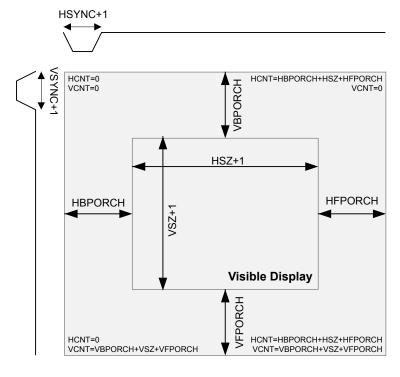

TFT Direct Drive can be used to automatically transfer frame data stored in either internal or external memory to a TFT display without frame buffer. The EBI generates the necessary RGB control signals for the TFT display and it coordinates and aligns the pixel data transfers accordingly. The Direct Drive engine is enabled by setting the DD bitfield in the EBI\_TFTCTRL register to either INTERNAL or EXTERNAL. The RGB interface consists of 8 or 16 data lines on EBI\_AD together with the EBI\_DATAEN, EBI\_VSYNC, EBI\_HSYNC and EBI\_DCLK control signals. EBI\_TFTCSn indicates whether the DD bitfield is programmed to DISABLED or not. Whether Direct Drive is active or not can also be read via the DDACT status bit in the EBI\_STATUS register.

The dimensions of the visible display are defined in the VSZ and HSZ bitfields of the EBI\_TFTSIZE register. Hardware automatically adds 1 to the size programmed in these bitfields. The front and back porch sizes are defined in the HFPORCH, HBPORCH, VFPORCH and VBPORCH bitfields of the EBI\_TFTHPORCH and EBI\_TFTVPORCH registers. The porch and visible display sizes define the number of EBI\_DCLK pulses per line and the number of lines per frame according to the following equations.

Number of EBI\_DCLK pulses per line = HBPORCH + (HSZ + 1) + HFPORCH

Number of lines per frame = VBPORCH + (VSZ + 1) + VFPORCH

The horizontal and vertical synchronization pulses begin at the starts of the horizontal and vertical back porch intervals respectively. For the HSYNC pulse a delayed start position can be defined in the HSYNCSTART bitfield of the EBI\_TFTHPORCH register. The end of the HSYNC pulse is not delayed and therefore the HSYNC pulse width is shortened when using a non-zero HSYNCSTART. The widths, or rather end positions, of the HSYNC and VSYNC synchronization pulses are defined in the HSYNC and VSYNC bitfields of the EBI\_TFTSIZE register respectively. The horizontal synchronization pulse width is specified in pixels. The vertical synchronization pulse width is specified in lines. Hardware automatically adds 1 to the width programmed in these bitfields. The EBI\_TFTSIZE bitfields are shown in the following figure. When Direct Drive is enabled, the VCNT and HCNT bitfields in the EBI\_TFTSTATUS register show how the frame display progresses. VCNT is a counter containing the current line position in a frame. It counts from 0 (first line in the vertical back porch) to VBPORCH + VSZ + VFPORCH (last line in the vertical front porch). HCNT is a counter containing the current pixel position within a line. It counts from 0 (first pixel in the horizonal back porch) to HBPORCH + HSZ + HFPORCH (last pixel in the horizontal front porch).

Total width = HBPORCH + (HSZ + 1) + HFPORCH

Total height = VBPORCH + (VSZ + 1) + VFPORCH

Figure 14.33. EBI TFT Size

While the Direct Drive engine is transferring frame data from internal or external memory to the TFT, the EBI can still be used for other EBI transfers to external devices. The interleaving of such EBI transfers with transfers originating from the Direct Drive engine is controlled via the INTERLEAVE field in the EBI\_TFTCTRL register. Interleaving can be limited to occur only during the vertical and horizontal porch intervals by setting the INTERLEAVE field to PORCH. EBI accesses outside the porch intervals while INTERLEAVE is set to

PORCH can cause the insertion of a high number of wait states on the AHB bus. In case the TFT dot clock EBI\_DCLK is relatively slow compared to the external device access time, interleaving can also be allowed during the active interval of the TFT by setting the INTERLEAVE bitfield to ONEPERDCLK or UNLIMITED. In both cases interleaving during the porch intervals is unlimited as it is when the PORCH setting is used. If INTERLEAVE is set to ONEPERDCLK then at most 1 EBI access is inserted per EBI\_DCLK period in the active display interval at the point immediately after the pixel transfer. Wait states are inserted on the AHB bus while waiting for this insertion point. The access time of such an interleaved transfer should be guaranteed by software to fit in the free interval between pixel transfers as indicated in Figure 14.39 EBI TFT Pixel Timing on page 274. If INTERLEAVE is set to UNLIMITED, which is the default, then there are no restrictions on performing EBI transactions during Direct Drive operation. Although transactions related to Direct Drive have priority over other EBI transactions, jitter on the EBI\_DCLK can be introduced in case an EBI transaction is ongoing while the Direct Drive engine wants to insert its next transaction. In case the programmed EBI\_DCLK period can not be met, the DDJIT interrupt flag in the EBI\_IF register is set and the EBI\_DCLK period is stretched to accommodate the delayed pixel data.

**Note:** If INTERLEAVE is limited to PORCH only and zero porch sizes are programmed in the EBI\_TFTHPORCH and EBI\_TFTVPORCH registers, then no slots are left open for interleaving traffic and therefore interleaving EBI accesses can never finish.

#### 14.3.16.1 Direct Drive from Internal Memory

Any internal memory can be used as the frame source location for Direct Drive. Direct Drive display from internal memory is started by setting the DD bitfield in the EBI\_TFTCTRL register to INTERNAL. The TFT controller indicates that the pixel buffer EBI\_TFTDD is empty and needs to be filled by raising the corresponding DMA request. This DMA request is initially set and it is cleared when EBI\_TFTDD is written. It is set again once the pixel data has been transferred to the display. One DMA request is generated for each visible pixel. The Direct Drive engine will automatically align the data written to EBI\_TFTDD according to the setup and hold requirements with respect to EBI\_DCLK and send it out to the TFT via the EBI\_AD lines. Whether the EBI\_TFTDD buffer is full or empty is also signaled by the DDEMPTY interrupt flag in the EBI\_IF register and by the TFTDDEMPTY status bit in the EBI\_STATUS register. Given the relatively low performance of using software polling and interrupts compared to using DMA, these non-DMA mechanisms are only advised for very low pixel rates. If pixel data is not provided in time the EBI\_DCLK will be stretched to accommodate the late pixel data and the Direct Drive Jitter interrupt flag DDJIT in the EBI\_IF register is set. The following figure shows the setup for Direct Drive from internal memory.

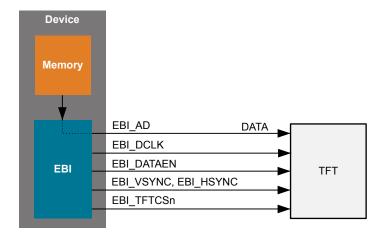

Figure 14.34. EBI TFT Direct Drive from Internal Memory

#### 14.3.16.2 Direct Drive from External Memory

Direct Drive can also use an external memory bank as the frame source location. The used bank is defined in the BANKSEL bitfield of the EBI\_TFTCTRL register. Direct Drive display from external memory is started by setting the DD bitfield in the EBI\_TFTCTRL register to EXTERNAL. Data is then streamed directly from the external memory to the TFT. The following figures show the setup for Direct Drive from external memory when using non-multiplexed and multiplexed address and data lines.

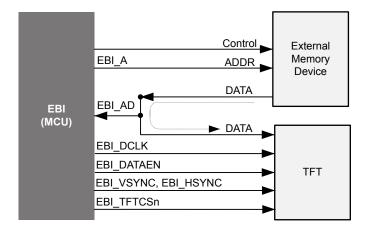

Figure 14.35. EBI TFT Direct Drive from External Memory (Non-Multiplexed Address/Data)

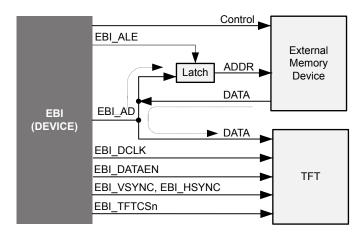

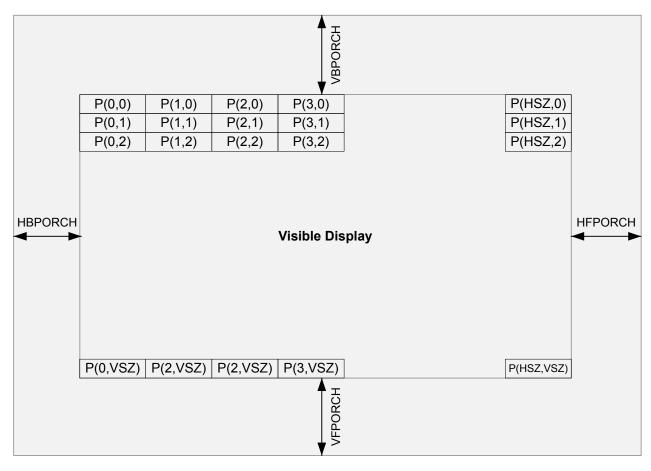

Figure 14.36. EBI TFT Direct Drive from External Memory (Multiplexed Address/Data)

The start address for the frame transfer is defined in the EBI TFTFRAMEBASE register. The Direct Drive address is automatically incremented for each visible pixel and it does therefore not depend on the programmed porch sizes. The address increment depends on the WIDTH bitfield in the EBI TFTCTRL register. The increment per visible pixel is 1 if the WIDTH bitfield in the EBI TFTCTRL register is programmed to BYTE and it is 2 if WIDTH is programmed to HALFWORD. Additionally a horizontal stride is added to the Direct Drive address at the end of each visible line. This stride can be programmed in the HSTRIDE bitfield of the EBI TFTSTRIDE register. The first visible pixel always corresponds to the address defined in the EBI\_TFTFRAMEBASE register. On either the vertical or horizontal synchronization event, as defined in the FBCTRIG bitfield of the EBI TFTCTRL register, the EBI TFTFRAMEBASE register is copied into an internal frame base buffer (FBC). This allows software to reprogram the EBI TFTFRAMEBASE register based on VSYNC or HSYNC interrupts, which in turn can be used to for example implement double buffering or scrolling schemes. The HSYNC and VSYNC interrupts are generated at the same time as the local copy of EBI TFTFRAMEBASE is made. If software reprograms EBI TFTFRA-MEBASE in the interrupt service routine, then the new value will only be used for address generation of the next line (in case FBCTRIG equals HSYNC) or the next frame (in case FBCTRIG equals VSYNC). For example, when FBCTRIG equals HSYNC and the interrupt service routine triggered by the HSYNC interrupt reads VCNT as 0, then a software update of EBI TFTFRAMEBASE will take effect for Direct Drive addresses of the line which corresponds to a VCNT value of 1. Note that the EBI\_TFTSTRIDE register is not relevant in case the FBCTRIG is set to HSYNC as the HSYNC events reloads the internal frame base copy (FBC) with EBI TFTFRAMEBASE at the start of each line. The Direct Drive address computation is summarized in the following figure.

FBCTRIG = VSYNC:

Local frame base copy FBC gets assigned with EBI\_TFTFRAMEBASE on every EBI\_VSYNC stobe.

Direct Drive Address for pixel P(x,y) = FBC + (x \* PSZ) + (y \* ((PSZ \* (HSZ + 1)) + HSTRIDE))

FBCTRIG = HSYNC:

Local frame base copy FBC gets assigned with EBI\_TFTFRAMEBASE on every EBI\_HSYNC stobe.

Direct Drive Address for pixel P(x,y) = FBC + (x \* PSZ)

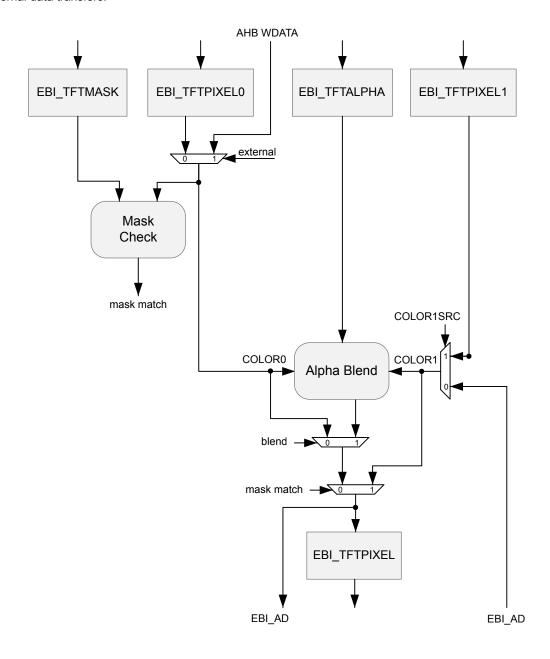

The address increment per pixel (PSZ) is 1 if the WIDTH bitfield in EBI\_TFTCTRL is programmed to BYTE and 2 if the WIDTH bitfield is programmed to HALFWORD.

Figure 14.37. EBI Direct Drive Address

**Note:** In case that the memory bank used for external Direct Drive is defined as 16-bit wide, then the Direct Drive address is internally shifted one bit to the right before being output on the EBI\_AD or EBI\_A lines.

## 14.3.17 Alpha Blending and Masking

Automatic alpha blending and masking can be performed on AHB data written to or via the EBI. Alpha blending combines a foreground color with a background color into a new blended color and is further described in 14.3.17.1 Alpha Blending. Masking is a mechanism to suppress writes matching a specific color. It is used to preserve the background color and is further described in 14.3.17.2 Masking. Masking, if enabled, is applied before alpha blending as shown in the following figure. Masking and alpha blending can be used for both internal and external data transfers.

external = (MASKBLEND == EMASK) or (MASKBLEND == EALPHA) or (MASKBLEND == EMASKEALPHA)

blend = (MASKBLEND == IALPHA) or (MASKBLEND == EALPHA)

Figure 14.38. EBI TFT Alpha Blending and Masking

## 14.3.17.1 Alpha Blending

Automatic alpha blending can be performed on AHB data written to or via the EBI. Alpha blending can be enabled for either internal or external writes by setting the MASKBLEND bitfield in the EBI\_TFTCTRL register. Internal writes are writes to the internal EBI\_TFTPIXEL0 register. External writes are writes to the external device attached to the bank defined in the BANKSEL bitfield of the EBI\_TFTCTRL register. Alpha blending works on two data items: a foreground Color0 = {R0, G0, B0} and a background Color1 = {R1, G1, B1}. These data items are encoded in either 565 RGB or 555 RGB format as defined in the RGBMODE bitfield of the EBI\_TFTCTRL register. In case that the 555 RGB format is used, only the 15 least significant bits of Color0 and Color1 are used for the alpha blending operation itself. The most significant bit of the foreground Color0 is passed on unmodified as the most significant bit of the alpha blending result. Alpha blending is performed according to the following formula:

$$AlphaBlend(Color0, Color1) = \frac{((R0, G0, B0) \times EBI\_TFTALPHA) + ((R1, G1, B1) \times (256 - EBI\_TFTALPHA))}{256}$$

The 9-bit alpha blending factor is defined in the EBI\_TFTALPHA register. The maximum allowed value for EBI\_TFTALPHA is 256. An alpha value of 0 corresponds to a fully transparent color, whereas an alpha value of 256 corresponds to a fully opaque color. The RGB Color0 data is taken from either the internal write data (written to EBI\_TFTPIXEL0) or from the external write data (written to bank BANKSEL). The Color0 source selection is based on the MASKBLEND bitfield of the EBI\_TFTCTRL register. Internal write data is used for MASKBLEND settings equal to IMASK, IALPHA, or IMASKIALPHA. External write data is used for MASKBLEND settings equal to EMASK, EALPHA, or EMASKEALPHA. The RGB data for Color1 is read from either the BANKSEL memory bank or from the EBI\_TFTPIXEL1 register as defined in the COLOR1SRC bitfield of the EBI\_TFTCTRL register. The alpha blended result will be written to the BANKSEL memory bank for external writes or to the EBI\_TFTPIXEL register for internal writes. For transactions involving an external memory device, the automatic transaction translation rules as described in 14.3.11 Data Access Width apply. For example, 1 32-bit wide AHB write to a 16-bit wide external memory can be used to automatically perform 2 16-bit alpha blending operations into external memory. Three configurations of data source and destination are supported as described next.

In-place alpha blending into external memory is performed by writing RGB data D to address A in bank BANKSEL with COLOR1SRC set to MEM and MASKBLEND set to EMASK, EALPHA, or EMASKEALPHA. Note that in this case the EBI automatically translates the AHB write transaction into a read-modify-write sequence for the external memory.

Memory[A] = AlphaBlend(D, Memory[A])

Alpha blending into external memory with a Color1 from register is performed by writing RGB data D to address A in bank BANKSEL with COLOR1SRC set to PIXEL1 and MASKBLEND set to EMASK, EALPHA, or EMASKEALPHA:

Memory[A] = AlphaBlend(D, EBI TFTPIXEL1)

Internal alpha blending into register EBI\_TFTPIXEL is performed by writing RGB data D to EBI\_TFTPIXEL0 with COLOR1SRC set to PIXEL1 and MASKBLEND set to IMASK, IALPHA, or IMASKEALPHA. This alpha blending interface is intended for use by both the Cortex-M4 and the DMA controller. For DMA operation three DMA requests are generated. One DMA request indicating that EBI\_TFTPIXEL0 requires new data, one DMA request indicating that EBI\_TFTPIXEL1 requires new data, and one DMA request indicating that new blended data is available in EBI\_TFTPIXEL. The write into EBI\_TFTPIXEL0 triggers the alpha blending operation. If software wants to reprogram EBI\_TFTPIXEL1, then this should be done before the EBI\_TFTPIXEL0 write, which triggers the alpha blending. The status of the internal alpha blending interface can also be read via the TFTPIXEL0EMPTY, TFTPIXEL1EMPTY, and TFTPIXELFULL bits in the EBI\_STATUS register.

EBI\_TFTPIXEL = AlphaBlend(EBI\_TFTPIXEL0, EBI\_TFTPIXEL1)

#### 14.3.17.2 Masking

The masking feature can be used to suppress writes. Instead of the write data, the original background color of a pixel is kept. Masking is supported for writes to an external device and for writes to internal register EBI\_TFTPIXELO. The 16-bit data value corresponding to the write data to be masked is defined in the EBI\_TFTMASK register. Masking is always based on 16-bit data and it does not depend on the RGB mode defined in the RGBMODE bitfield of the EBI\_TFTCTRL register. For transactions involving an external memory device, the automatic transaction translation rules as described in 14.3.11 Data Access Width apply. For example, 1 32-bit wide AHB write to a 16-bit wide external memory can be used to perform masking operations on both 16-bit transactions to the external device. Masking can for example be used when drawing an icon with rounded corners into an external frame buffer. Such an icon can be written to the frame buffer using a 2-dimensional copy action. If the color of a pixel outside the rounded corners is set to match the value defined in the EBI\_TFTMASK register, then such a matching data transfer is suppressed. The resulting image in the frame buffer will keep its original background around the corners of the icon.

External masking is enabled by setting the EMASK bit in the EBI\_TFTCTRL register to 1. If enabled, writes to the memory bank defined in the BANKSEL bitfield of the EBI\_TFTCTRL register are suppressed in case the write data matches the value in EBI\_TFTMASK.

Internal masking is enabled by setting the IMASK bit in the EBI\_TFTCTRL register to 1. If enabled and EBI\_TFTPIXEL0 is written with data matching EBI\_TFTMASK, then the background color from EBI\_TFTPIXEL1 is copied into EBI\_TFTPIXEL. If enabled and EBI\_TFTPIXEL0 is written with data not matching EBI\_TFTMASK, then the color from EBI\_TFTPIXEL0 (possibly alpha blended with EBI\_TFTPIXEL1) is written into EBI\_TFTPIXEL. The three DMA requests and EBI\_STATUS bits as described for internal alpha blending also apply for internal masking.

### 14.3.18 Direct Drive Timing

The timing definition for operating a TFT display in Direct Drive mode depends on where the frame buffer source is located. In case internal memory is used as source, then only the TFT timing as defined in the EBI\_TFTTIMING register is relevant. In case external memory is used as the source memory, then both the timing parameters of the TFT display and the timing parameters of the memory bank defined in the BANKSEL bitfield of the EBI\_TFTCTRL register are relevant.

The minimum dot clock, EBI DCLK, period is defined in the DCLKPERIOD bitfield of the EBI TFTTIMING register. This parameter has a minimum duration of 1 cycle, which is set by HW, and writing a value n to this bitfield results in an extended duration of 1+n cycles. At cycle 0 (and then periodically with period DCLKPERIOD + 1) the EBI DCLK inactive edges are generated. At the cycle defined in the TFTSTART bitfield of the EBI\_TFTTIMING the TFT Direct Drive transaction is started. The TFTSTART bitfield can be used to define the duty cycle of the EBI\_DCLK. This parameter has a minimum duration of 1 cycle, which is set by HW, and writing a value n to this bitfield results in an extended duration of 1+n cycles. After performing the required actions to produce the required TFT pixel data on the EBI AD lines, the TFT transaction will pass through its TFTSETUP and TFTHOLD states as indicated in the first following figure. In this figure, the duration of the states in the TFT transaction is defined by the corresponding uppercase name above the state and it is expressed in internal clock cycles. The TFT setup and hold times are set in the TFTHOLD and TFTSETUP bitfields in the EBI\_TFTTIM-ING register. Writing a value m to one of these bitfields results in a duration of the corresponding state of m internal clock cycles. If these parameters are set to 0, it effectively means that the state is skipped. The TFT setup and hold timing is with respect to the active edge of EBI\_DCLK as defined in the DCLKPOL bitfield in the EBI\_TFTPOLARITY register. The TFT setup and hold timing applies to all TFT signals: EBI AD, EBI DATAEN, EBI VSYNC, EBI HSYNC and EBI TFTCSn. The active EBI DCLK edge is generated in between the TFTSETUP and TFTHOLD states. The TFTSTART bitfield therefore impacts the position of the active EBI DCLK edge. The later the TFT transaction is started, the later it will transition from its TFTSETUP to TFTHOLD state. If needed, the EBI DCLK period is automatically stretched beyond the DCLKPERIOD to complete the TFT transaction. EBI DCLK period stretching occurs when the TFT transaction does not complete in the specified time, which in turn can occur because of the following reasons:

- Specified timing parameters are conflicting. This can for example happen if the TFT setup plus hold time is programmed to be longer than the EBI\_DCLK period.
- TFT transaction is delayed by an ongoing EBI transaction. This transaction interference can be controlled by setting the transaction interleaving strategy in the INTERLEAVE bitfield of the EBI\_TFTCTRL register.
- TFT transaction data is not delivered in time. For internal Direct Drive this is caused by the Cortex-M4 or DMA not delivering the data in time. For external Direct Drive the timing parameters defining the external device read access might not allow the TFT transaction to complete in time.

In case the specified DCLK\_PERIOD is not met, the DDJIT interrupt flag in the EBI\_IF register will be set.

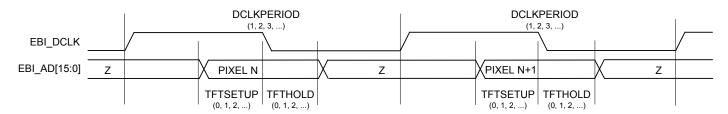

Figure 14.39. EBI TFT Pixel Timing

When driving the TFT from internal memory, the TFT timing is defined in the EBI\_TFTTIMING register as shown in the following figure. Before each TFT transaction to the visible part of the display, the EBI will request new pixel data via an interrupt or DMA request. At the time specified in the TFTSTART bitfield of the EBI\_TFTTIMING register (and when pixel data has been provided), the TFT transaction will start. For internal Direct Drive the TFT state machine will place the pixel data on the EBI\_AD lines during the TFTWDATA state after which the state machine will pass through the programmable TFTSETUP and TFTHOLD states.

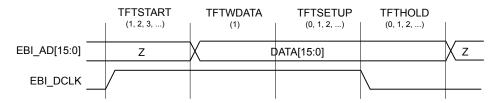

Figure 14.40. EBI TFT Direct Drive Internal Timing

When the TFT is driven directly from an external memory, the timing definitions for the bank defined in the BANKSEL bitfield of the EBI\_TFTCTRL register and those for the TFT are both used by Direct Drive to generate transactions satisfying the requirements of both the memory device and the TFT display. The timing definition for the external memory device should be programmed according to its requirements independent of the TFT timing. The following figure shows an example of the Direct Drive engine accessing an external

memory using the multiplexed 16-bit data, 16-bit address (D16A16ALE) mode. The TFTSETUP and TFTHOLD states are now enclosed within the read transaction states of the chosen mode. The external device read transaction is started at a time as defined by TFTSTART. The read strobe on EBI\_REn is automatically extended in duration to satisfy the TFT setup and hold requirements defined in the TFTSETUP and TFTHOLD bitfields.

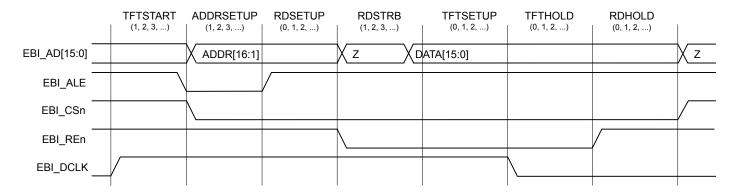

Figure 14.41. EBI TFT Direct Drive External Timing

The timing parameters related to the horizontal timing are shown in the following figure. These parameters are defined as pixel or EBI\_DCLK counts. The horizontal porch widths are defined in the HBPORCH and HFPORCH bitfields of the EBI\_TFTHPORCH register. A porch which has its width parameter programmed to 0 will be skipped. The width and start position of the horizontal synchronization pulse EBI\_HSYNC is programmed via the HSYNC and HSYNCSTART bitfields in the EBI\_TFTHPORCH register.

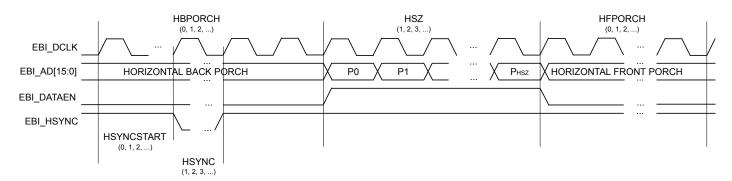

Figure 14.42. EBI TFT Horizontal Porch Timing

The timing parameters related to the vertical timing are shown in the following figure. These parameters are defined as line or EBI\_HSYNC counts. The vertical porch widths are defined in the VBPORCH and VFPORCH bitfields of the EBI\_TFTVPORCH register. A porch which has its width parameter programmed to 0 will be skipped. The width of the vertical synchronization pulse EBI\_VSYNC is programmed via the VSYNC bitfield in the EBI\_TFTVPORCH register.

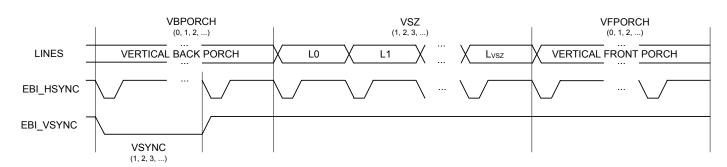

Figure 14.43. EBI TFT Vertical Porch Timing

The active edge of the EBI\_DCLK and the other TFT related signals are by default driven off the positive edge of the internal clock. The edges of the EBI\_DCLK can also be driven off the negative edge of the internal clock by setting the SHIFTDCLK bitfield in the EBI\_TFTCTRL register to 1. The Direct Drive engine then shifts the active DCLK edge 1/2 an internal cycle into the TFTHOLD state. Effectively the length of TFTSETUP state is increased by 1/2 an internal cycle, whereas the length of the TFTHOLD state is decreased by 1/2 an internal cycle. SHIFTDCLK should not be set if TFTHOLD is set to zero cycles. The effect of the SHIFTDCLK bitfield is shown in the following figures for a setup using the falling EBI\_DCLK clock as its active edge.

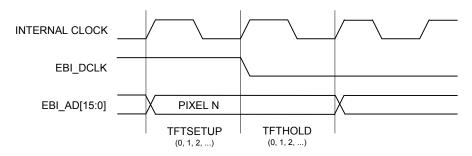

Figure 14.44. EBI TFT Pixel Timing: EBI\_DCLK driven off Positive Edge Internal Clock

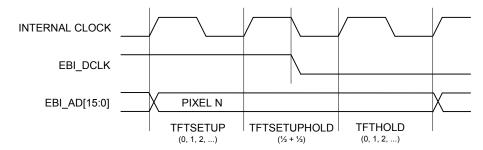

Figure 14.45. EBI TFT Pixel Timing: EBI\_DCLK driven off Negative Edge Internal Clock

### 14.3.19 Control Signal Polarity

It is possible to individually configure the control signals to be active high/low by setting or clearing the appropriate bits in the EBI\_PO-LARITY register. When the ITS bitfield in the EBI\_CTRL register is set to 0, the polarities defined in the EBI\_POLARITY register applies to all 4 memory banks. When ITS is set to 1 each memory bank uses an individual polarity definition. In this case register EBI\_POLARITY only applies to bank 0. Timing for bank n is then defined in the EBI\_POLARITYn register.

The TFT control signals can also be individually configured to be active high/low by setting or clearing the appropriate bits in the EBI TFTPOLARITY register.

## 14.3.20 Pin Configuration

In order to give the EBI access to the external pins of the EFM32WG, the GPIO must be configured accordingly. The lines must be set to Push-Pull, which is described in detail in the GPIO section.

All the EBI pins are enabled in the EBI\_ROUTE register. The EBI\_AD, EBI\_WEn and EBI\_REn pins are all enabled by the EBIPEN bit, the EBI\_CSn pins are enabled by the corresponding CSxPEN bit, the EBI\_ALE pin is enabled by the ALEPEN bit, the EBI\_BL pins are enabled by the BLPEN bit, the EBI\_NANDWEN and EBI\_NANDREN pins are enabled by the NANDPEN bit, the TFT pins EBI\_DCLK, EBI\_VSYNC and EBI\_HSYNC are all enabled by the TFTPEN bit, the EBI\_DATAEN pin is enabled by the DATAENPEN bit, the EBI\_CSTFT pin is enabled by the CSTFTPEN bit, the EBI\_A pins are enabled by the ALB and APEN bitfields, and the EBI\_ARDY pin is enabled by the ARDYPEN bit of the EBI\_ROUTE register.

For some of the EBI pins, alternative pin locations can be chosen by setting the LOCATION bitfield in the EBI\_ROUTE register. These alternative locations are specified in the datasheet.

#### 14.3.21 Interrupts

The TFT controller has 6 separate interrupt flags (VSYNC, HSYNC, VBPORCH, VFPORCH, DDEMPTY, DDJIT) in EBI IF.

The VSYNC, HSYNC, VBPORCH, and VFPORCH interrupt flags indicate various synchronization points during the display of a frame. The following figure shows the timing of the VSYNC, HSYNC, VBPORCH, and VFPORCH interrupt flags. The VSYNC and HSYNC flags are set at the beginning of a frame and at the beginning of a line respectively. The VBPORCH and VFPORCH flags are set at the end of the vertical back porch and at the beginning of the vertical front porch respectively (provided that the related porch is defined with a non-zero width).

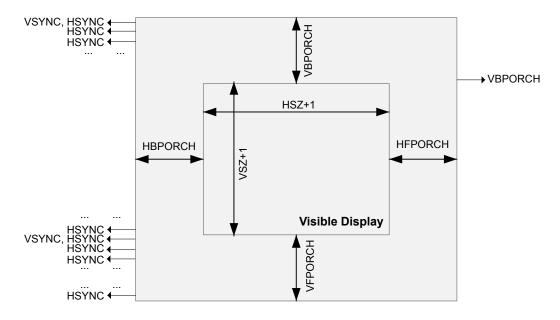

Figure 14.46. EBI TFT Interrupts

The DDEMPTY interrupt flag indicates that the EBI\_TFTDD register is empty during Direct Drive from internal memory. The DDJIT interrupt flag indicates that the DCLKPERIOD is not met during Direct Drive operation.

Setting one of the interrupt flags will result in an EBI interrupt if the corresponding interrupt enable bit is set in the EBI\_IEN register. All generated interrupts from the EBI will activate the same interrupt vector when enabled.

## 14.3.22 DMA Request

In internal Direct Drive mode, when the DD bitfield in EBI\_TFTCTRL register is INTERNAL, the TFT controller sends out a DMA request when the pixel buffer EBI\_TFTDD is empty and needs to be filled. This request is initially set and it is cleared when EBI\_TFTDD is written. It is set again once the pixel data has been transferred to the display. One DMA request is generated for each visible pixel.

The masking and alpha blending hardware uses three DMA requests related to the status of thee internal masking and alpha blending registers EBI\_TFTPIXEL0, EBI\_TFTPIXEL1, and EBI\_TFTPIXEL. The DMA request for EBI\_TFTPIXEL0 indicates that new data can be written to be used for internal masking or alpha blending. This request is initially set and it is cleared when EBI\_TFTPIXEL0 is written. The request is set again when EBI\_TFTPIXEL is read. The DMA request for EBI\_TFTPIXEL1 is initially set and it is cleared when EBI\_TFTPIXEL1 is written. Only when both EBI\_TFTPIXEL0 and EBI\_TFTPIXEL1 have been written, will a EBI\_TFTPIXEL read set the DMA request for EBI\_TFTPIXEL1 again. The DMA request for EBI\_TFTPIXEL indicates whether new masked and/or blended data is available for reading in EBI\_TFTPIXEL or not. It is set after completion of internal masking and alpha blending in reaction to a write to EBI\_TFTPIXEL0. It is cleared when EBI\_TFTPIXEL is read.

## 14.4 Register Map

The offset register address is relative to the registers base address.

	This field sets the TF	T Direct Drive In	terleave m	ode.
	Value	Mode		Description
	0	UNLIMITED		Allow unlimited interleaved EBI accesses per EBI_DCLK period. This can cause jitter on the EBI_DCLK
	1	ONEPERDCL	.K	Allow 1 interleaved EBI access per EBI_DCLK period.
	2	PORCH		Only allow EBI accesses during TFT porches.
9	FBCTRIG	0	RW	TFT Frame Base Copy Trigger
	Sets the trigger on whon the internal buffer.		AMEBASE	is copied into an internal buffer. Direct Drive address generation is based
	Value	Mode		Description
	0	VSYNC		TFTFRAMEBASE is buffered on the vertical synchronization event EBI_VSYNC.
	1	HSYNC		TFTFRAMEBASE is buffered on the horizontal synchronization event EBI_HSYNC.
8	SHIFTDCLKEN	0	RW	TFT EBI_DCLK Shift Enable
				n off the negative (instead of the positive) edge of the internal clock. FFTHOLD in EBI_TFTTIMING is at least 1.
7:5	Reserved	To ensure contions.	mpatibility v	with future devices, always write bits to 0. More information in 2.1 Conven-
4:2	MASKBLEND	0x0	RW	TFT Mask and Blend Mode
	This field sets the Ma	sk and Blend M	ode.	
	Value	Mode		Description
	0	DISABLED		Masking and Blending are disabled.
	1	IMASK		Internal Masking is enabled.
	2	IALPHA		Internal Alpha Blending is enabled.
	3	IMASKIALPH	A	Internal Masking and Alpha Blending are enabled.
	5	EMASK		External Masking is enabled.
	6	EALPHA		External Alpha Blending is enabled.
	7	EMASKEALP	HA	External Masking and Alpha Blending are enabled.
1:0	DD	0x0	RW	TFT Direct Drive Mode
	This field sets the Dir	ect Mode.		
	Value	Mode		Description
	0	DISABLED		Direct Drive is disabled.

Bit	Name	Reset	Access	Description
	1	INTERNAL		Direct Drive from internal memory enabled and started.
	2	EXTERNAL		Direct Drive from external memory enabled and started.

#### 15. USB - Universal Serial Bus Controller

#### **Quick Facts**

#### What?

The USB is a full-speed/low-speed USB 2.0 compliant USB Controller that can be used in OTG Dual Role Device, Device and Host configurations. The on-chip 3.3V regulator delivers up to 50 mA and can also be used to power external components, eliminating the need for an external LDO. The on-chip regulator allows the system to run from a battery utilizing the full voltage range of the EFM32 still being compliant with the 3.3V +/- 10% USB voltage range.

#### Why?

USB provides a robust, industry-standard way to interface PCs and other portable devices.

#### How?

The flexible and highly software-configurable architecture of the USB Controller makes it easy to implement both device- and host-capable solutions. The on-chip OTG PHY with software controllable pull-up and pull-down resistors, VBUS comparators and ID-line detection reduces the number of external components to a minimum. Third-party USB software stacks are also available, reducing the development time substantially. By utilizing the very low energy consumption in EM2, the USB device will be able to wake up and perform tasks several times a second without violating the 2.5 mA maximum average current during suspend.

#### 15.1 Introduction

The USB is a full-speed/low-speed USB 2.0 compliant OTG host/device controller. The architecture is very flexible and allows the USB to be used in On-the-go (OTG) Dual-Role Device, Device and Host-only configurations. The USB supports HNP and SRP protocols and both OTG Revisions 1.3 and 2.0 are supported. The on-chip voltage regulator and PHY reduces the number of external components to a minimum. A switchable external 5V supply or step-up regulator is needed for OTG Dual Role Device and Host configurations.

#### 15.2 Features

- Fully compliant with Universal Serial Bus Specification, Revision 2.0
- Supports full-speed (12 Mbit/s) and low-speed (1.5 Mbit/s) host and device
- Dedicated Internal DMA Controller
- 12 software-configurable endpoints (6 IN, 6 OUT) in addition to endpoint 0
- · 2 kB endpoint memory
- · Resume/Reset detection in EM2 (during suspend)
- · SRP detection in EM2 (during host session off)
- · Soft connect/disconnect
- Full OTG support
  - · Compliant with On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification, Revision 2.0
  - · Compliant with USB On-The-Go Supplement, Revision 1.3
  - Supports Host Negotiation Protocol (HNP) and Session Request Protocol (SRP)
- · On-chip PHY
  - · Internal pull-up and pull-down resistors
  - · Voltage comparators for monitoring VBUS voltage
  - · A/B Device identification using ID line
  - · Charge/discharge of VBUS for VBUS-pulsing
- · Internal 3.3 V Regulator
  - Output voltage: 3.3V
  - · Output current: 50 mA
  - Input voltage range: 4.0 5.5V
  - · Enabled automatically when input voltage applied
  - · Low quiescent current: 100 μA
  - · Dedicated input pin allows regulator to be used in OTG and host configurations
  - · Output pin can be used to power the EFM32 itself as well as external components
  - · Regulator voltage output sense feature for detecting USB plug/unplug events (also available in EM2/3)

#### 15.3 USB System Description

A block diagram of the USB is shown in the following figure.

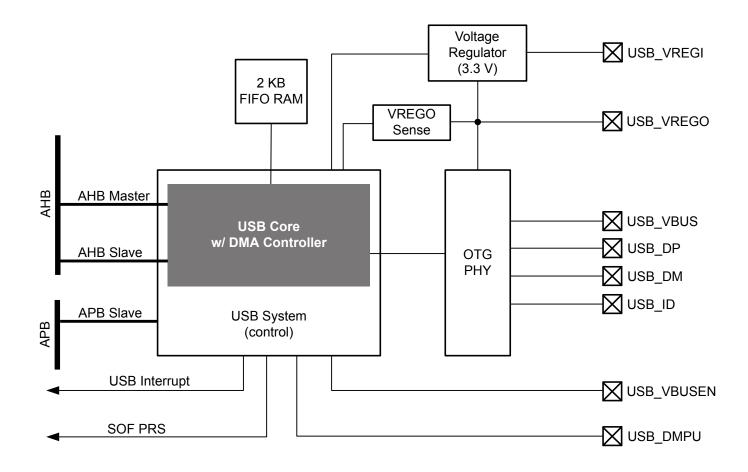

Figure 15.1. USB Block Diagram

The USB consists of a digital logic part, a 2 kB endpoint RAM, OTG PHY and a voltage regulator with output voltage sensor. The voltage regulator provides a stable 3.3 V supply for the PHY, but can also be used to power the EFM32 itself as well as external components.

The digital logic of the USB is split into two parts: system and core.

The system part is accessed using USB registers from offset 0x000 to 0x018 and controls the voltage regulator and enabling/disabling of the PHY and USB pins. This part is clocked by HFCORECLK<sub>USB</sub> and is accessed using an APB slave interface. The system part can thus be accessed independently of the core part, without HFCORECLK<sub>USBC</sub> running.

The core part is clocked by HFCORECLK<sub>USBC</sub> and is accessed using an AHB slave interface. This interface is used for accessing the FIFO contents and the registers in the core part starting at offset 0x3C000. An additional master interface is used by the internal DMA controller of the core. The core part takes care of all the USB protocol related functionality. The clock to the system part must not be disabled when the core part is active.

There are 8 pins associated with the USB. USB\_VBUS should be connected to the VBUS (5V) pin on the USB receptacle. It is connected to the voltage comparators and current sink/source in the PHY. USB\_DP and USB\_DM are the USB D+ and D- pins. These are the USB data signaling pins. USB\_ID is the OTG ID pin used to detect the device type (A or B). This pin can be left unconnected when not used. USB\_VREGI is the input to the voltage regulator and USB\_VREGO is the regulated output. USB\_VBUSEN is used to turn on and off VBUS power when operating as host-only or OTG A-Device. USB\_DMPU is used to enable/disable an external D- pull-up resistor. This is needed for low-speed device only. USB\_VBUSEN and USB\_DMPU will be high-impedance until the pins are enabled from software. Thus, if a defined level is required during start-up an external pull-up/pull-down can be used.

#### 15.3.1 USB Initialization

The USB requires the device to run from a 48 MHz crystal (2500 ppm or better). The core part of the USB will always run from HFCOR-ECLK<sub>USBC</sub> which is HFCLK undivided (48 MHz). The current consumption for the rest of the device can be reduced by dividing down HFCORECLK using the CMU\_HFCORECLKDIV register. Bandwidth requirements for the specific USB application must be taken into account when dividing down HFCORECLK.

Follow these steps to enable the USB:

- 1. Enable the clock to the system part by setting USB in CMU HFCORECLKEN0.
- 2. If the internal USB regulator is bypassed (by applying 3.3V on USB\_VREGI and USB\_VREGO externally), disable the regulator by setting VREGDIS in USB\_CTRL.
- 3. If the PHY is powered from VBUS using the internal regulator, the VREGO sense circuit should be enabled by setting VREGOSEN in USB\_CTRL.
- 4. Enable the USB PHY pins by setting PHYPEN in USB ROUTE.
- 5. If host or OTG dual-role device, set VBUSENAP in USB\_CTRL to the desired value and then enable the USB\_VBUSEN pin in USB\_ROUTE. Set the MODE for the pin to PUSHPULL.
- 6. If low-speed device, set DMPUAP in USB\_CTRL to the desired value and then enable the USB\_DMPU pin in USB\_ROUTE. Set the MODE for the pin to PUSHPULL.
- 7. Make sure HFXO is ready and selected. The core part requires the undivided HFCLK to be 48 MHz when USB is active (during suspend/session-off a 32 kHz clock is used).
- 8. Enable the clock to the core part by setting USBC in CMU HFCORECLKENO.
- 9. Wait for the core to come out of reset. This is easiest done by polling a core register with non-zero reset value until it reads a non-zero value. This takes approximately 20 48-MHz cycles.
- 10. Start initializing the USB core as described in USB Core Description.

## 15.3.2 Configurations

The USB can be used as Device, OTG Dual Role Device or Host. The sections below describe the different configurations. External ESD protection and series resistors for impedance matching are required. The voltage regulator requires a 4.7  $\mu$ F external decoupling capacitor on the input and a 1  $\mu$ F external decoupling capacitor on the output. Decoupling not related to USB is not shown in the figures.

## 15.3.2.1 Bus-Powered Device

A bus-powered device configuration is shown in the following figure. In this configuration, the voltage regulator powers the PHY and the EFM32 at 3.3 V. The voltage regulator output (USB VREGO) can also be used to power other components of the system.

In this configuration, the VREGO sense circuit should be left disabled.

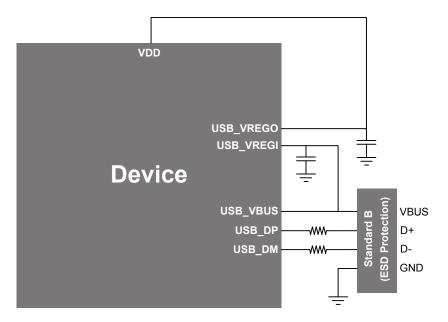

Figure 15.2. Bus-Powered Device

#### 15.3.2.2 Self-Powered Device

A self-powered device configuration is shown in the following figure. When the USB is configured as a self-powered device, the voltage regulator is typically used to power the PHY only, although it may also be used to power other 3.3 V components. When the USB is connected to a host, the voltage regulator is activated. Software can detect this event by enabling the VREGO Sense High (VREGOSH) interrupt. The PHY pins can then be enabled and USB traffic can start. The VREGO Sense Low (VREGOSL) interrupt can be used to detect when VBUS voltage disappears (for example if the USB cable is unplugged).

In this configuration, the VREGO sense circuit must be enabled.

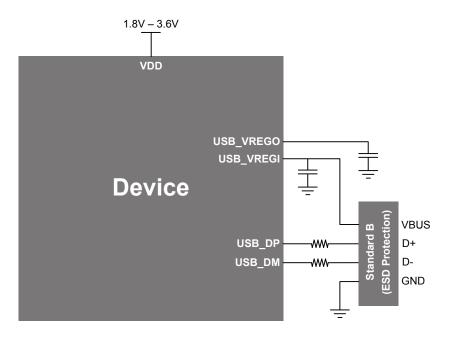

Figure 15.3. Self-Powered Device

## 15.3.2.3 Self-Powered Device (with Bus-Power Switch)

A self-powered device (with bus-power switch) may switch power supply to VBUS when connected to a host. This is typically useful for extending the life of battery-powered devices and enables the use of coin-cell driven systems with low maximum peak current. The external components required typically include 2 transistors, 2 diodes and a few resistors. See application note for details. This allows seamless power supply switching between a battery and the voltage regulator output.

The VREGO Sense High interrupt is used to detect when VBUS becomes present. Software can then enable the external transistor connected to USB\_VREGO, effectively switching the power source. A regular GPIO pin is used to control this transistor. If necessary, the application may have to reduce the current consumption before switching to the USB power source. If VBUS voltage is removed, the circuit switches automatically back to the battery power supply. If necessary software must react quickly to this event and reduce the current consumption (for example by reducing the clock frequency) to avoid excessive voltage drop. This configuration is shown in the following figure.

In this configuration, the VREGO sense circuit must be enabled.

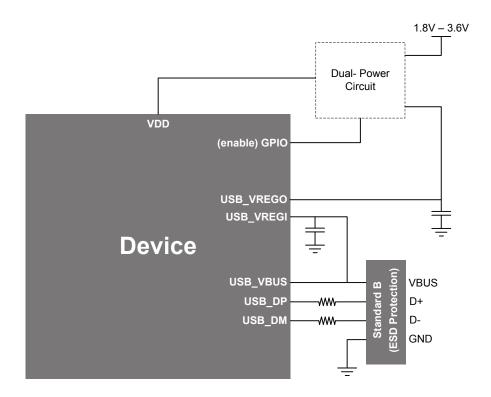

Figure 15.4. Self-Powered Device (with Bus-Power Switch)

# 15.3.2.4 OTG Dual Role Device (5V)

An OTG Dual Role Device (5V) configuration is shown in the following figure. When 5V is available, the internal regulator can be used to power the EFM32. An external power switch is needed to control VBUS power. For over-current detection a regular GPIO input pin with interrupt is used. The application should turn off or limit VBUS power when over-current is detected. In OTG mode, the maximum VBUS decoupling capacitance is  $6.5 \, \mu F$ .

In this configuration, the VREGO sense circuit should be left disabled.

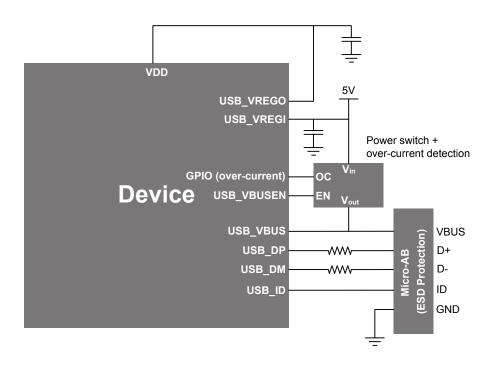

Figure 15.5. OTG Dual Role Device (5V)

# 15.3.2.5 OTG Dual Role Device (5V Step-Up Regulator)

An OTG Dual Role Device (5V step-up regulator) configuration is shown in the following figure. When 5V is not available, an external 5V step-up regulator is needed. In this configuration, the voltage for the EFM32 must be in the range 3.0V - 3.6V. In this mode the voltage regulator is bypassed by connecting both the input and output to the external supply. This effectively causes the PHY to be powered directly from the external 3.0 - 3.6 V supply. The voltage regulator should be disabled when operating in this mode. For overcurrent detection a regular GPIO input pin with interrupt is used. The application should turn off or limit VBUS power when over-current is detected. In OTG mode, the maximum VBUS decoupling capacitance is  $6.5 \, \mu F$ .

In this configuration, the VREGO sense circuit should be left disabled.

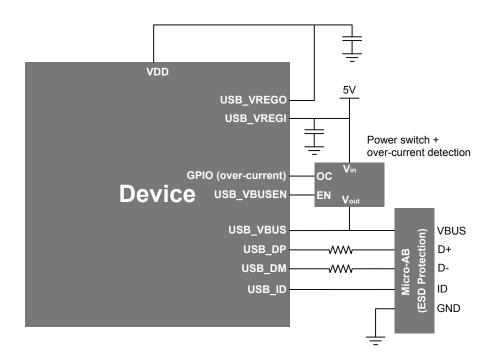

Figure 15.6. OTG Dual Role Device (5V Step-Up Regulator)

## 15.3.2.6 Host

A host configuration is shown in the following figure. In this example a 5V step-up regulator is used. If 5V is available, a power switch can be used instead, as shown in Figure 15.5 OTG Dual Role Device (5V) on page 329. The host configuration is equal to OTG Dual Role Device, except for the USB\_ID pin which is not used and the USB connector which is a USB Standard-A Connector. In host mode, the minimum VBUS decoupling capacitance is  $96 \, \mu F$ .

In this configuration, the VREGO sense circuit should be left disabled.

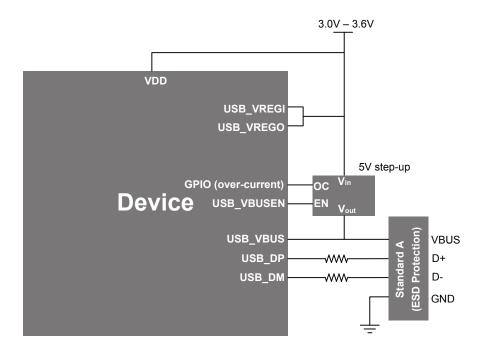

Figure 15.7. Host

#### 15.3.3 PHY

The USB includes an internal full-speed/low-speed PHY with built-in pull-up/pull-down resistors, VBUS comparators and ID line state sensing. During suspend, the PHY enters a low-power state where only the single-ended receivers are active. The PHY is disabled by default and should be enabled by setting PHYPEN in USB ROUTE before the USB core clock is enabled.

The PHY is powered by the internal voltage regulator output (USB\_VREGO). To power the PHY directly from an external source (for example an external 3.3 V LDO), connect both USB\_VREGO and USB\_VREGI to the external 3.3 V supply voltage. To stop the quiescent current present with the voltage regulator enabled in this configuration, disable the regulator by setting VREGDIS in USB\_CTRL after power up. Then the regulator is effectively bypassed.

When VREGO Sense is enabled, the PHY is automatically disabled internally when the VREGO Sense output is low. This will happen if VBUS-power disappears. The application can detect this by keeping the VREGO Sense Low Interrupt enabled. Note that PHYPEN in USB\_ROUTE will not be set to 0 in this case. Also, the PHY must always be disabled manually when there is no voltage applied to VREGO.

#### 15.3.4 Voltage Regulator

The voltage regulator is used to regulate the 5 V VBUS voltage down to 3.3 V which is the operating voltage for the PHY.

A decoupling capacitor is required on USB\_VREGI and USB\_VREGO. Note that the USB standard requires the total capacitance on VBUS to be 1 µF minimum and 10 uF maximum for regular devices. OTG devices can have maximum 6.5 µF capacitance on VBUS.

The voltage regulator is enabled by default and can thus be used to power the EFM32 itself. Systems not using the USB should disable the regulator by setting VREGDIS in USB\_CTRL. A voltage sense circuit monitors the output voltage and can be used to detect when the voltage regulator becomes active. This sense circuit can also be used to detect when the voltage drops (typically due to the USB cable being unplugged). If regulator voltage monitoring is not required (i.e. it is known that the VREGO voltage is always present), the sense circuit should be left disabled.

During suspend, the bias current for the regulator can be reduced if the current requirements in EM2/3 are low. The bias current in EM2/3 is controlled by BIASPROGEM23 in USB\_CTRL. When EM2/3 is entered, the bias current for the regulator switches to what is specified in BIASPROGEM23 in USB\_CTRL. When entering EM0 again (due to USB resume/reset signaling or any other wake-up interrupt) the regulator switches back to using the value specified in BIASPROGEM01 in USB\_CTRL.

#### 15.3.5 Interrupts and PRS

Interrupts from the core and system part share a common USB interrupt line to the CPU. The interrupt flags for the system part are grouped together in the USB\_IF register. The interrupt events from the core are controlled by several core interrupt flag registers.

There are two PRS outputs from the USB: SOF and SOFSR. In Host mode, SOF toggles every time an SOF is generated. In Device mode, SOF toggles every time an SOF token is received from the USB host or when an SOF token is missed at the start of frame. In Host mode, SOFSR toggles every time an SOF is successfully transmitted. In Device mode, SOFSR toggles only when a valid SOF token is received from the USB host. Both PRS outputs must be synchronized in the PRS when used (i.e. it is an asynchronous PRS output). The edge-to-pulse converter in the PRS can be used to convert the edges into pulses if needed. The PRS outputs go to 0 in EM2/3.

#### 15.3.6 USB in EM2

During suspend and session-off EM2 should be used to save power and meet the average current requirements dictated by the USB standard. Before entering EM2, HFCORECLK<sub>USBC</sub> must be switched from 48 MHz to 32 kHz (LFXO or LFRCO). This is done using the CMU\_CMD and CMU\_STATUS registers. While HFCORECLK<sub>USBC</sub> is 32 kHz, the USB core registers (starting from offset 0x3C000) cannot be accessed and the the internal DMA in the USB core will not be able to access the AHB bus. Upon EM2 wake-up, HFCORECLK<sub>USBC</sub> must be switched back to 48 MHz before accessing the core registers. The device always starts up from HFRCO so software must restart HFXO and switch from HFRCO to HFXO. The USB system clock, HFCORECLK<sub>USB</sub>, must be kept enabled during EM2. The USB system registers can be accessed immediately upon EM2 wake-up, while running from HFRCO. Follow the steps outlined the USB Core Description when entering EM2 during suspend and session-off.

The FIFO content is lost when entering EM2. In addition, most of the USB core registers are reset and therefore need to be backed up in RAM.

EM3 cannot be used when the USB is active. However, EM3 can be used while waiting for the internal voltage regulator to be activated (i.e. VBUS becomes 5V).

## 15.4 USB Core Description

This section describes the programming requirements for the USB Core in Host and Device modes.

Important features/parameters for the core are:

- · HNP- and SRP-Capable OTG (Device and Host)
- · Internal DMA (Buffer Pointer Based)
- · Dedicated TX FIFOS for each endpoint in device mode
- 6 IN/OUT endpoints in addition to endpoint 0 (in device mode)
- 14 host channels (in host mode)
- · Dynamic FIFO sizing
- · Non-Periodic Request Queue Depth: 8
- · Host Mode Periodic Request Queue Depth: 8

The core has the following limitations:

- · Link Power Management (LPM) is not supported
- · ADP is not supported

## 15.4.1 Overview: Programming the Core

Each significant programming feature of the core is discussed in a separate section.

This chapter uses abbreviations for register names and their fields. For detailed information on registers, see the end of this chapter.

The application must perform a core initialization sequence. If the cable is connected during power-up, the Current Mode of Operation bit in the Core Interrupt register (USB\_GINTSTS.CURMOD) reflects the mode. The core enters Host mode when an "A" plug is connected, or Device mode when a "B" plug is connected.

This section explains the initialization of the core after power-on. The application must follow the initialization sequence irrespective of Host or Device mode operation. All core global registers are initialized according to the core's configuration.

- 1. Program the following fields in the Global AHB Configuration (USB\_GAHBCFG) register.
  - · DMA Mode bit
  - · AHB Burst Length field
  - · Global Interrupt Mask bit = 1
  - · Non-periodic TxFIFO Empty Level (can be enabled only when the core is operating in Slave mode as a host.)
  - Periodic TxFIFO Empty Level (can be enabled only when the core is operating in Slave mode)
- 2. Program the following field in the Global Interrupt Mask (USB GINTMSK) register:
  - USB GINTMSK.RXFLVLMSK = 0
- 3. Program the following fields in USB\_GUSBCFG register.
  - · HNP Capable bit
  - · SRP Capable bit
  - · External HS PHY or Internal FS Serial PHY Selection bit
  - · Time-Out Calibration field
  - · USB Turnaround Time field
- 4. The software must unmask the following bits in the USB\_GINTMSK register.
  - OTG Interrupt Mask
  - · Mode Mismatch Interrupt Mask
- 5. The software can read the USB\_GINTSTS.CURMOD bit to determine whether the core is operating in Host or Device mode. The software the follows either the 15.4.1.1 Host Initialization or 15.4.1.2 Device Initialization sequence.

**Note:** The core is designed to be interrupt-driven. Polling interrupt mechanism is not recommended: this may result in undefined resolutions.

**Note:** In device mode, just after Power On Reset or a Soft Reset, the USB\_GINTSTS.SOF bit is set to 1 for debug purposes. This status must be cleared and can be ignored.

#### 15.4.1.1 Host Initialization

To initialize the core as host, the application must perform the following steps.

- 1. Program USB GINTMSK.PRTINT to unmask.
- 2. Program the USB\_HCFG register to select full-speed host.
- 3. Program the USB\_HPRT.PRTPWR bit to 1. This drives VBUS on the USB.
- 4. Wait for the USB HPRT.PRTCONNDET interrupt. This indicates that a device is connect to the port.
- 5. Program the USB\_HPRT.PRTRST bit to 1. This starts the reset process.
- 6. Wait at least 10 ms for the reset process to complete.
- 7. Program the USB\_HPRT.PRTRST bit to 0.
- 8. Wait for the USB HPRT.PRTENCHNG interrupt.
- 9. Read the USB\_HPRT.PRTSPD field to get the enumerated speed.
- 10. Program the USB\_HFIR register with a value corresponding to the selected PHY clock. At this point, the host is up and running and the port register begins to report device disconnects, etc. The port is active with SOFs occurring down the enabled port.
- 11. Program the RXFSIZE register to select the size of the receive FIFO.
- 12. Program the NPTXFSIZE register to select the size and the start address of the Non-periodic Transmit FIFO for non-periodic transactions.
- 13. Program the USB HPTXFSIZ register to select the size and start address of the Periodic Transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel as described in 15.4.1.2 Device Initialization.

### 15.4.1.1.1 Host Connection

The following steps explain the host connection flow:

- 1. When the USB Cable is plugged to the Host port, the core triggers USB\_GINTSTS.CONIDSTSCHNG interrupt.
- When the Host application detects USB\_GINTSTS.CONIDSTSCHNG interrupt, the application can perform one of the following actions:
  - Turn on VBUS by setting USB\_HPRT.PRTPWR = 1 or
  - · Wait for SRP Signaling from Device to turn on VBUS.
- 3. The PHY indicates VBUS power-on by detecting a VBUS valid voltage level.
- 4. When the Host Core detects the device connection, it triggers the Host Port Interrupt (USB\_GINTSTS.PRTINT) to the application.
- 5. When USB\_GINTSTS.PRTINT is triggered, the application reads the USB\_HPRT register to check if the Port Connect Detected (USB\_HPRT.PRTCONNDET) bit is set or not.

#### 15.4.1.1.2 Host Disconnection

The following steps explain the host disconnection flow:

1. When the Device is disconnected from the USB Cable (but the cable is still connected to the USB host), the Core triggers USB GINTSTS.DISCONNINT (Disconnect Detected) interrupt.

**Note:** If the USB cable is disconnected from the Host port without removing the device, the core generates an additional interrupt - USB GINTSTS.CONIDSTSCHNG (Connector ID Status Change).

2. The Host application can choose to turn off the VBUS by programming USB\_HPRT.PRTPWR = 0.

### 15.4.1.2 Device Initialization

The application must perform the following steps to initialize the core at device on, power on, or after a mode change from Host to Device.

- 1. Program the following fields in USB DCFG register.
  - · Device Speed
  - · Non-Zero-Length Status OUT Handshake
  - · Periodic Frame Interval
- 2. Program the USB GINTMSK register to unmask the following interrupts.
  - USB Reset
  - · Enumeration Done
  - · Early Suspend
  - USB Suspend
- 3. Wait for the USB\_GINTSTS.USBRST interrupt, which indicates a reset has been detected on the USB and lasts for about 10 ms. On receiving this interrupt, the application must perform the steps listed in 15.4.4.1.1 Initialization on USB Reset.
- 4. Wait for the USB\_GINTSTS.ENUMDONE interrupt. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the USB\_DSTS register to determine the enumeration speed and perform the steps listed in 15.4.4.1.2 Initialization on Enumeration Completion.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

#### 15.4.1.2.1 Device Connection

The device connect process varies depending on the if the VBUS is on or off when the device is connected to the USB cable.

#### When VBUS is on When the Device is Connected

If VBUS is on when the device is connected to the USB cable, there is no SRP from the device. The device connection flow is as follows:

- 1. The device triggers the USB GINTSTS.SESSREQINT [bit 30] interrupt bit.
- 2. When the device application detects the USB\_GINTSTS.SESSREQINT interrupt, it programs the required bits in the USB\_DCFG register.
- 3. When the Host drives Reset, the Device triggers USB\_GINTSTS.USBRST [bit 12] on detecting the Reset. The host then follows the USB 2.0 Enumeration sequence.

### When VBUS is off When the Device is Connected

If VBUS is off when the device is connected to the USB cable, the device initiates SRP in OTG Revision 1.3 mode. The device connection flow is as follows:

- The application initiates SRP by writing the Session Request bit in the OTG Control and Status register. The core perform data-line pulsing followed by VBUS pulsing.
- 2. The host starts a new session by turning on VBUS, indicating SRP success. The core interrupts the application by setting the Session Request Success Status Change bit in the OTG Interrupt Status register.
- 3. The application reads the Session Request Success bit in the OTG Control and Status register and programs the required bits in USB\_DCFG register.
- 4. When Host drives Reset, the Device triggers USB\_GINTSTS.USBRST on detecting the Reset. The host then follows the USB 2.0 Enumeration sequence.

#### 15.4.1.2.2 Device Disconnection

The device session ends when the USB cable is disconnected or if the VBUS is switched off by the Host.

The device disconnect flow is as follows:

- 1. When the USB cable is unplugged or when the VBUS is switched off by the Host, the Device core trigger USB\_GINTSTS.OTGINT [bit 2] interrupt bit.
- When the device application detects USB\_GINTSTS.OTGINT interrupt, it checks that the USB\_GOTGINT.SESENDDET (Session End Detected) bit is set to 1.

#### 15.4.1.2.3 Device Soft Disconnection

The application can perform a soft disconnect by setting the Soft disconnect bit (SFTDISCON) in Device Control Register (USB DCTL).

#### Send/Receive USB Transfers -> Soft Disconnect -> Soft reset -> USB Device Enumeration

Sequence of operations:

- 1. The application configures the device to send or receive transfers.
- 2. The application sets the Soft disconnect bit (SFTDISCON) in the Device Control Register (USB\_DCTL).
- 3. The application sets the Soft Reset bit (CSFTRST) in the Reset Register (USB GRSTCTL).
- 4. Poll the USB GRSTCTL register until the core clears the soft reset bit, which ensures the soft reset is completed properly.
- 5. Initialize the core according to the instructions in 15.4.1.2 Device Initialization.

#### Suspend -> Soft Disconnect -> Soft Reset -> USB Device Enumeration

Sequence of operations:

- 1. The core detects a USB suspend and generates a Suspend Detected interrupt.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core puts the PHY in suspend mode, and the PHY clock stops.
- 3. The application clears the Stop PHY Clock bit in the Power and Clock Gating Control register, and waits for the PHY clock to come back. The core takes the PHY back to normal mode, and the PHY clock comes back.
- 4. The application sets the Soft disconnect bit (SFTDISCON) in Device Control Register (USB DCTL).
- 5. The application sets the Soft Reset bit (CSFTRST) in the Reset Register (USB GRSTCTL).
- 6. Poll the USB\_GRSTCTL register until the core clears the soft reset bit, which ensures the soft reset is completed properly.
- 7. Initialize the core according to the instructions in 15.4.1.2 Device Initialization.

# 15.4.2 Modes of Operation

- 15.4.2.1 Overview: DMA/Slave Modes
- 15.4.2.2 DMA Mode
- 15.4.2.3 Slave Mode

#### 15.4.2.1 Overview: DMA/Slave Modes

The application can operate the core in either of two modes:

- In 15.4.2.2 DMA Mode The core fetches the data to be transmitted or updates the received data on the AHB.
- In 15.4.2.3 Slave Mode The application initiates the data transfers for data fetch and store.

#### 15.4.2.2 DMA Mode

In DMA Mode, the OTG host uses the AHB master Interface for transmit packet data fetch (AHB to USB) and receive data update (USB to AHB). The AHB master uses the programmed DMA address (USB\_HCx\_DMAADDR register in host mode and USB\_DIEPx\_DMAADDR/USB\_DOEPx\_DMAADDR register in device mode) to access the data buffers.

### 15.4.2.2.1 Transfer-Level Operation

In DMA mode, the application is interrupted only after the programmed transfer size is transmitted or received (provided the core detects no NAK/Timeout/Error response in Host mode, or Timeout/CRC Error in Device mode). The application must handle all transaction errors. In Device mode, all the USB errors are handled by the core itself.

#### 15.4.2.2.2 Transaction-Level Operation

This mode is similar to transfer-level operation with the programmed transfer size equal to one packet size (either maximum packet size, or a short packet size).

## 15.4.2.3 Slave Mode

In Slave mode, the application can operate the core either in transaction-level (packet-level) operation or in pipelined transaction-level operation.

#### 15.4.2.3.1 Transaction-Level Operation

The application handles one data packet at a time per channel/endpoint in transaction-level operations. Based on the handshake response received on the USB, the application determines whether to retry the transaction or proceed with the next, until the end of the transfer. The application is interrupted on completion of every packet. The application performs transaction-level operations for a channel/endpoint for a transmission (host: OUT/device: IN) or reception (host: IN/device: OUT) as shown in the following figures.

#### **Host Mode**

For an OUT transaction, the application enables the channel and writes the data packet into the corresponding (Periodic or Non-periodic) transmit FIFO. The core automatically writes the channel number into the corresponding (Periodic or Non-periodic) Request Queue, along with the last DWORD write of the packet. For an IN transaction, the application enables the channel and the core automatically writes the channel number into the corresponding Request queue. The application must wait for the packet received interrupt, then empty the packet from the receive FIFO.

### **Device Mode**

For an IN transaction, the application enables the endpoint, writes the data packet into the corresponding transmit FIFO, and waits for the packet completion interrupt from the core. For an OUT transaction, the application enables the endpoint, waits for the packet received interrupt from the core, then empties the packet from the receive FIFO.

**Note:** The application has to finish writing one complete packet before switching to a different channel/endpoint FIFO. Violating this rule results in an error.

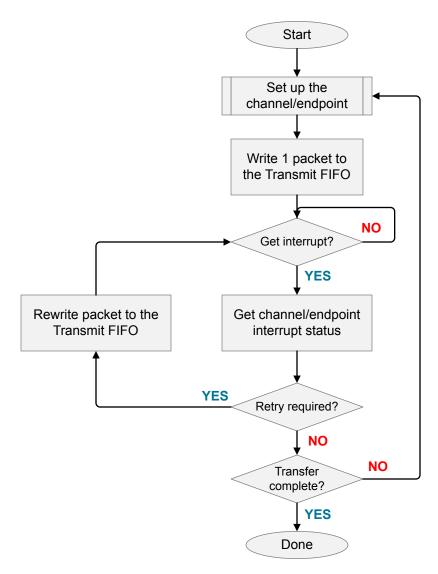

Figure 15.8. Transmit Transaction-Level Operation in Slave Mode

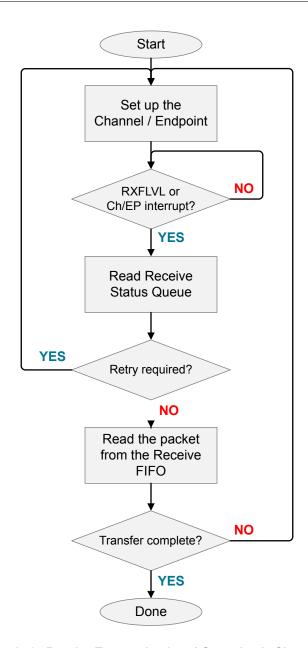

Figure 15.9. Receive Transaction-Level Operation in Slave Mode

## 15.4.2.3.2 Pipelined Transaction-Level Operation

The application can pipeline more than one transaction (IN or OUT) with pipelined transaction-level operation, which is analogous to Transfer mode in DMA mode. In pipelined transaction-level operation, the application can program the core to perform multiple transactions. The advantage of this mode compared to transaction-level operation is that the application is not interrupted on a packet basis.

### 15.4.2.3.2.1 Host Mode

For an OUT transaction, the application sets up a transfer and enables the channel. The application can write multiple packets back-to-back for the same channel into the transmit FIFO, based on the space availability. It can also pipeline OUT transactions for multiple channels by writing into the HCHARn register, followed by a packet write to that channel. The core writes the channel number, along with the last DWORD write for the packet, into the Request queue and schedules transactions on the USB in the same order.

For an IN transaction, the application sets up a transfer and enables the channel, and the core writes the channel number into the Request queue. The application can schedule IN transactions on multiple channels, provided space is available in the Request queue. The core initiates an IN token on the USB only when there is enough space to receive at least of one maximum-packet-size packet of the channel in the top of the Request queue.

#### 15.4.2.3.2.2 Device Mode

For an IN transaction, the application sets up a transfer and enables the endpoint. The application can write multiple packets back-to-back for the same endpoint into the transmit FIFO, based on available space. It can also pipeline IN transactions for multiple channels by writing into the USB\_DIEPx\_CTL register followed by a packet write to that endpoint. The core writes the endpoint number, along with the last DWORD write for the packet into the Request queue. The core transmits the data in the transmit FIFO when an IN token is received on the USB.

For an OUT transaction, the application sets up a transfer and enables the endpoint. The core receives the OUT data into the receive FIFO, when it has available space. As the packets are received into the FIFO, the application must empty data from it.

From this point on in this chapter, the terms "Pipelined Transaction mode" and "Transfer mode" are used interchangeably.

### 15.4.3 Host Programming Model

Before you program the Host, read 15.4.1 Overview: Programming the Core and 15.4.2 Modes of Operation.

This section discusses the following topics:

- 15.4.3.1 Channel Initialization
- 15.4.3.2 Halting a Channel
- 15.4.3.3 Sending a Zero-Length Packet in Slave/DMA Modes
- 15.4.3.4 Handling Babble Conditions
- 15.4.3.5 Handling Disconnects
- 15.4.3.6 Host Programming Operations
  - 15.4.3.6.1 Writing the Transmit FIFO in Slave Mode
  - 15.4.3.6.2 Reading the Receive FIFO in Slave Mode

#### 15.4.3.1 Channel Initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps.

- 1. Program the USB\_GINTMSK register to unmask the following:
- 2. Channel Interrupt
  - Non-periodic Transmit FIFO Empty for OUT transactions (applicable for Slave mode that operates in pipelined transaction-level with the Packet Count field programmed with more than one).
  - Non-periodic Transmit FIFO Half-Empty for OUT transactions (applicable for Slave mode that operates in pipelined transaction-level with the Packet Count field programmed with more than one).
- 3. Program the USB USB HAINTMSK register to unmask the selected channels' interrupts.
- Program the HCINTMSK register to unmask the transaction-related interrupts of interest given in the Host Channel Interrupt register.
- 5. Program the selected channel's USB HCx TSIZ register.

Program the register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).

- 6. Program the selected channels' USB\_HCx\_DMAADDR register(s) with the buffer start address (DMA mode only).
- 7. Program the USB\_HCx\_CHAR register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the Channel Enable bit to 1 only when the application is ready to transmit or receive any packet).

Repeat the above steps for other channels.

**Note:** De-allocate channel means after the transfer has completed, the channel is disabled. When the application is ready to start the next transfer, the application re-initializes the channel by following these steps.

### 15.4.3.2 Halting a Channel

The application can disable any channel by programming the USB\_HCx\_CHAR register with the USB\_HCx\_CHAR.CHDIS and USB\_HCx\_CHAR.CHENA bits set to 1. This enables the host to flush the posted requests (if any) and generates a Channel Halted interrupt. The application must wait for the USB\_HCx\_INT.CHHLTD interrupt before reallocating the channel for other transactions. The host does not interrupt the transaction that has been already started on USB.

In Slave mode operation, before disabling a channel, the application must ensure that there is at least one free space available in the Non-periodic Request Queue (when disabling a non-periodic channel) or the Periodic Request Queue (when disabling a periodic channel). The application can simply flush the posted requests when the Request queue is full (before disabling the channel), by programming the USB\_HCx\_CHAR register with the USB\_HCx\_CHAR.CHDIS bit set to 1, and the USB\_HCx\_CHAR.CHENA bit reset to 0.

The core generates a RXFLVL interrupt when there is an entry in the queue. The application must read/ pop the USB\_GRXSTSP register to generate the Channel Halted interrupt.

To disable a channel in DMA mode operation, the application need not check for space in the Request queue. The host checks for space in which to write the Disable request on the disabled channel's turn during arbitration. Meanwhile, all posted requests are dropped from the Request queue when the USB\_HCx\_CHAR.CHDIS bit is set to 1.

The application is expected to disable a channel under any of the following conditions:

- 1. When a USB\_HCx\_INT.XFERCOMPL interrupt is received during a non-periodic IN transfer or high-bandwidth interrupt IN transfer (Slave mode only)
- 2. When a USB\_HCx\_INT.STALL, USB\_HCx\_INT.XACTERR, USB\_HCx\_INT.BBLERR, or USB\_HCx\_INT.DATATGLERR interrupt is received for an IN or OUT channel (Slave mode only). For high-bandwidth interrupt INs in Slave mode, once the application has received a DATATGLERR interrupt it must disable the channel and wait for a Channel Halted interrupt. The application must be able to receive other interrupts (DATATGLERR, NAK, Data, XACTERR, BBLERR) for the same channel before receiving the halt.
- 3. When a USB\_GINTSTS.DISCONNINT (Disconnect Device) interrupt is received. The application must check for the USB\_HPRT.PRTCONNSTS, because when the device directly connected to the host is disconnected, USB\_HPRT.PRTCONNSTS is reset. The software must issue a soft reset to ensure that all channels are cleared. When the device is reconnected, the host must issue a USB Reset.
- 4. When the application aborts a transfer before normal completion (Slave and DMA modes).

**Note:** In DMA mode, keep the following guideline in mind: Channel disable must not be programmed for periodic channels. At the end of the next frame (in the worst case), the core generates a channel halted and disables the channel automatically.

# 15.4.3.3 Sending a Zero-Length Packet in Slave/DMA Modes

To send a zero-length data packet, the application must initialize an OUT channel as follows.

- 1. Program the USB\_HCx\_TSIZ register of the selected channel with a correct PID, XFERSIZE = 0, and PKTCNT = 1.
- 2. Program the USB\_HCx\_CHAR register of the selected channel with CHENA = 1 and the device's endpoint characteristics, such as type, speed, and direction.

The application must treat a zero-length data packet as a separate transfer, and cannot combine it with a non-zero-length transfer.

### 15.4.3.4 Handling Babble Conditions

The core handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When the core detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already-written data in the Rx buffer and generates a Babble interrupt to the application.

When detects a port babble, it flushes the RxFIFO and disables the port. The core then generates a Port Disabled Interrupt (USB\_GINTSTS.PRTINT, USB\_HPRT.PRTENCHNG). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the Port Disabled interrupt) by checking USB\_HPRT.PRTOVRCURRACT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

## 15.4.3.5 Handling Disconnects

If the device is disconnected suddenly, a USB\_GINTSTS.DISCONNINT interrupt is generated. When the application receives this interrupt, it must issue a soft reset by programming the USB\_GRSTCTL.CSFTRST bit.

# 15.4.3.6 Host Programming Operations

The table below provides links to the programming sequence for the different types of USB transactions.

**Table 15.1. Host Programming Operations** 

Mode	IN	OUT/SETUP
Control	'	
Slave	15.4.3.6.5 Bulk and Control IN Transactions in Slave Mode	15.4.3.6.4 Bulk and Control OUT/SETUP Transactions in Slave Mode
DMA	15.4.3.6.8 Bulk and Control IN Transactions in DMA Mode	15.4.3.6.7 Bulk and Control OUT/SETUP Transactions in DMA Mode
Bulk	·	
Slave	15.4.3.6.5 Bulk and Control IN Transactions in Slave Mode	15.4.3.6.4 Bulk and Control OUT/SETUP Transactions in Slave Mode

## 15.4.3.6.1 Writing the Transmit FIFO in Slave Mode

The following figure shows the flow diagram for writing to the transmit FIFO in Slave mode. The host automatically writes an entry (OUT request) to the Periodic/Non-periodic Request Queue, along with the last DWORD write of a packet. The application must ensure that at least one free space is available in the Periodic/Non-periodic Request Queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in DWORDs. If the packet size is non-DWORD aligned, the application must use padding. The host determines the actual packet size based on the programmed maximum packet size and transfer size.

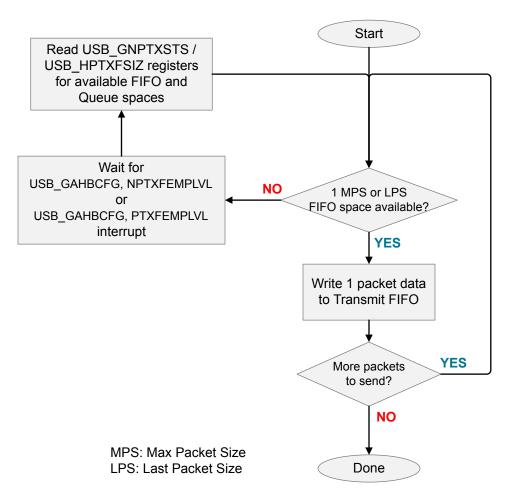

Figure 15.10. Transmit FIFO Write Task in Slave Mode

## 15.4.3.6.2 Reading the Receive FIFO in Slave Mode

The following figure shows the flow diagram for reading the receive FIFO in Slave mode. The application must ignore all packet statuses other than IN Data Packet (0b0010).

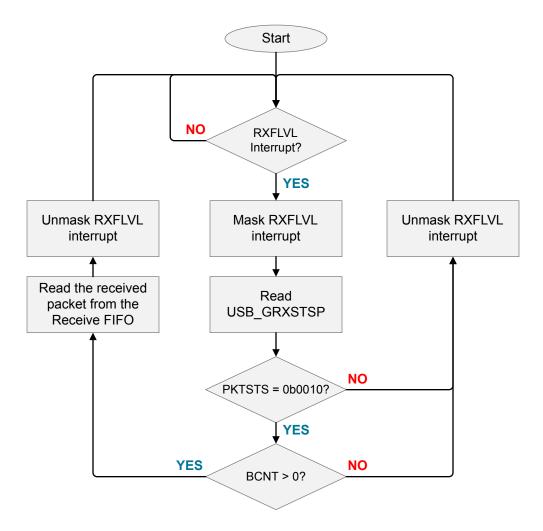

Figure 15.11. Receive FIFO Read Task in Slave Mode

# 15.4.3.6.3 Control Transactions in Slave Mode

Setup, Data, and Status stages of a control transfer must be performed as three separate transfers. Setup- Data- or Status-stage OUT transactions are performed similarly to the bulk OUT transactions explained in 15.4.3.6.4 Bulk and Control OUT/SETUP Transactions in Slave Mode. Data- or Status-stage IN transactions are performed similarly to the bulk IN transactions explained in 15.4.3.6.5 Bulk and Control IN Transactions in Slave Mode. For all three stages, the application is expected to set the USB\_HC1\_CHAR.EPTYPE field to Control. During the Setup stage, the application is expected to set the USB\_HC1\_TSIZ.PID field to SETUP.

## 15.4.3.6.4 Bulk and Control OUT/SETUP Transactions in Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization. See Figure 15.10 Transmit FIFO Write Task in Slave Mode on page 343 and 15.4.3.6.2 Reading the Receive FIFO in Slave Mode for Read or Write data to and from the FIFO in Slave mode.

A typical bulk or control OUT/SETUP pipelined transaction-level operation in Slave mode is shown in Figure 15.12 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in Slave Mode on page 346. See channel 1 (ch\_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The Non-periodic Transmit FIFO can hold two packets (128 bytes for FS).
- The Non-periodic Request Queue depth = 4.

### 15.4.3.6.4.1 Normal Bulk and Control OUT/SETUP Operations

The sequence of operations in the following figure (channel 1) is as follows:

- 1. Initialize channel 1 as explained in 15.4.3.1 Channel Initialization.
- 2. Write the first packet for channel 1.
- 3. Along with the last DWORD write, the core writes an entry to the Non-periodic Request Queue.
- 4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame.
- 5. Write the second (last) packet for channel 1.
- 6. The core generates the XFERCOMPL interrupt as soon as the last transaction is completed successfully.
- 7. In response to the XFERCOMPL interrupt, de-allocate the channel for other transfers.

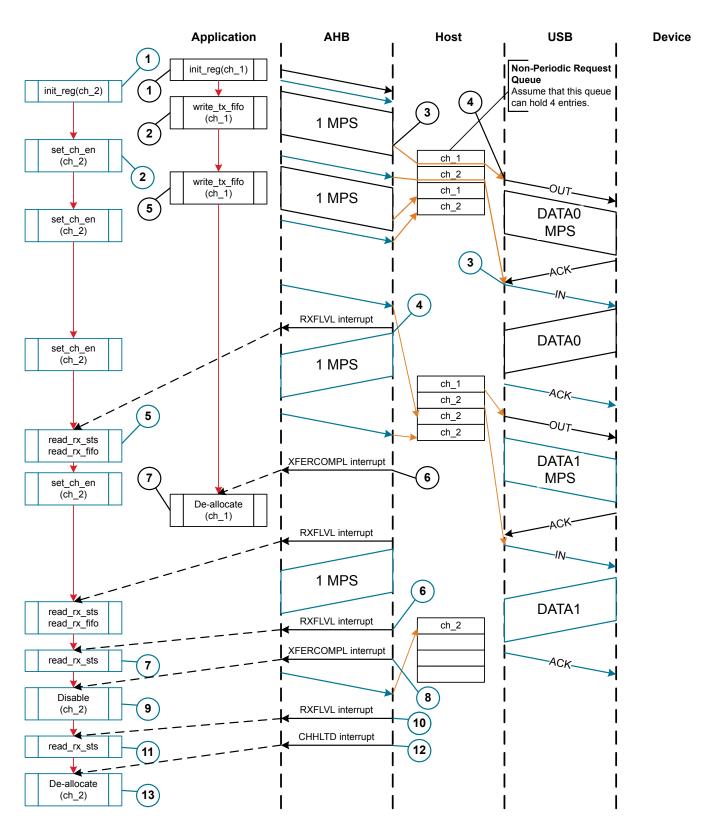

Figure 15.12. Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in Slave Mode

## 15.4.3.6.4.2 Handling Interrupts

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in Slave mode is shown in the following code samples.

```
Unmask (NAK/XACTERR/STALL/XFERCOMPL)
if (XFERCOMPL)
   Reset Error Count
   Mask ACK
   De-allocate Channel
else if (STALL)
   Transfer Done = 1
   Unmask CHHLTD
   Disable Channel
else if (NAK or XACTERR)
   Rewind Buffer Pointers
   Unmask CHHLTD
   Disable Channel
   if (XACTERR)
      Increment Error Count
      Unmask ACK
   else
      Reset Error Count
else if (CHHLTD)
   Mask CHHLTD
   if (Transfer Done or (Error_count == 3))
      De-allocate Channel
   else
      Re-initialize Channel
else if (ACK)
   Reset Error Count
   Mask ACK
```

The application is expected to write the data packets into the transmit FIFO when space is available in the transmit FIFO and the Request gueue. The application can make use of USB\_GINTSTS.NPTXFEMP interrupt to find the transmit FIFO space.

The application is expected to write the requests as and when the Request queue space is available and until the XFERCOMPL interrupt is received.

# 15.4.3.6.5 Bulk and Control IN Transactions in Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization. See Figure 15.10 Transmit FIFO Write Task in Slave Mode on page 343 and Figure 15.11 Receive FIFO Read Task in Slave Mode on page 344 for read or write data to and from the FIFO in Slave mode.

A typical bulk or control IN pipelined transaction-level operation in Slave mode is shown in Figure 15.12 Normal Bulk/Control OUT/ SETUP and Bulk/Control IN Transactions in Slave Mode on page 346. See channel 2 (ch\_2). The assumptions are:

- 1. The application is attempting to receive two maximum-sized packets (transfer size = 1,024 bytes).
- 2. The receive FIFO can contain at least one maximum-packet-size packet and two status DWORDs per packet (72 bytes for FS).
- 3. The Non-periodic Request Queue depth = 4.

## 15.4.3.6.5.1 Normal Bulk and Control IN Operations

The sequence of operations in Figure 15.12 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in Slave Mode on page 346 is as follows:

- 1. Initialize channel 2 as explained in 15.4.3.1 Channel Initialization.
- 2. Set the USB HC2 CHAR.CHENA bit to write an IN request to the Non-periodic Request Queue.
- 3. The core attempts to send an IN token after completing the current OUT transaction.
- 4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
- 5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
- 6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
- 7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (USB\_GRXSTSR.PKTSTS != 0b0010).
- 8. The core generates the XFERCOMPL interrupt as soon as the receive packet status is read.
- 9. In response to the XFERCOMPL interrupt, disable the channel (see 15.4.3.2 Halting a Channel) and stop writing the USB\_HC2\_CHAR register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the USB\_HC2\_CHAR register is written.
- 10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
- 11. Read and ignore the receive packet status.
- 12. The core generates a CHHLTD interrupt as soon as the halt status is popped from the receive FIFO.
- 13. In response to the CHHLTD interrupt, de-allocate the channel for other transfers.

**Note:** For Bulk/Control IN transfers, the application must write the requests when the Request queue space is available, and until the XFERCOMPL interrupt is received.

## 15.4.3.6.5.2 Handling Interrupts

The channel-specific interrupt service routine for bulk and control IN transactions in Slave mode is shown in the following code samples.

```
Unmask (XACTERR/XFERCOMPL/BBLERR/STALL/DATATGLERR)
if (XFERCOMPL)
   Reset Error Count
   Unmask CHHLTD
   Disable Channel
   Reset Error Count
   Mask ACK
else if (XACTERR or BBLERR or STALL)
   Unmask CHHLTD
   Disable Channel
   if (XACTERR)
      Increment Error Count
      Unmask ACK
else if (CHHLTD)
   Mask CHHLTD
   if (Transfer Done or (Error_count == 3))
      De-allocate Channel
   else
      Re-initialize Channel
else if (ACK)
   Reset Error Count
   Mask ACK
else if (DATATGLERR)
   Reset Error Count
```

# 15.4.3.6.6 Control Transactions in DMA Mode

Setup, Data, and Status stages of a control transfer must be performed as three separate transfers. Setup- and Data- or Status-stage OUT transactions are performed similarly to the bulk OUT transactions explained in 15.4.3.6.7 Bulk and Control OUT/SETUP Transactions in DMA Mode. Data- or Status-stage IN transactions are performed similarly to the bulk IN transactions explained in 15.4.3.6.8 Bulk and Control IN Transactions in DMA Mode. For all three stages, the application is expected to set the USB\_HC1\_CHAR.EPTYPE field to Control. During the Setup stage, the application is expected to set the USB\_HC1\_TSIZ.PID field to SETUP.

#### 15.4.3.6.7 Bulk and Control OUT/SETUP Transactions in DMA Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization.

This section discusses the following topics:

- 15.4.3.6.7.1 Overview
- 15.4.3.6.7.2 Normal Bulk and Control OUT/SETUP Operations
- 15.4.3.6.7.3 NAK Handling with DMA
- 15.4.3.6.7.4 Handling Interrupts

## 15.4.3.6.7.1 Overview

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The Non-periodic Transmit FIFO can hold two packets (128 bytes for FS).
- The Non-periodic Request Queue depth = 4.

### 15.4.3.6.7.2 Normal Bulk and Control OUT/SETUP Operations

The sequence of operations in Figure 15.12 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in Slave Mode on page 346 is as follows:

- 1. Initialize and enable channel 1 as explained in 15.4.3.1 Channel Initialization.
- The host starts fetching the first packet as soon as the channel is enabled. For DMA mode, the host uses the programmed DMA address to fetch the packet.
- 3. After fetching the last DWORD of the second (last) packet, the host masks channel 1 internally for further arbitration.
- 4. The host generates a CHHLTD interrupt as soon as the last packet is sent.
- 5. In response to the CHHLTD interrupt, de-allocate the channel for other transfers.

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in DMA mode is shown in 15.4.3.6.7.4 Handling Interrupts.

## 15.4.3.6.7.3 NAK Handling with DMA

- 1. The Host sends a Bulk OUT Transaction.
- 2. The Device responds with NAK.
- 3. If the application has unmasked NAK, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding of buffer pointers and re-initializing the Channel without application intervention.
- 4. When the Device returns an ACK, the core continues with the transfer.

Optionally, the application can utilize these interrupts. If utilized by the application:

- · The NAK interrupt is masked by the application.
- The core does not generate a separate interrupt when NAK is received by the Host functionality.

# **Application Programming Flow**

- 1. The application programs a channel to do a bulk transfer for a particular data size in each transaction.
  - · Packet Data size can be up to 512 KBytes
  - · Zero-length data must be programmed as a separate transaction.
- 2. Program the transfer size register with:
  - · Transfer size
  - · Packet count
  - 3. Program the DMA address.
  - 4. Program the USB\_HCx\_CHAR to enable the channel.
  - 5. The Interrupt handling by the application is as depicted in the flow diagram.

**Note:** The NAK interrupts are still generated internally. The application can mask off these interrupts from reaching it. The application can use these interrupts optionally.

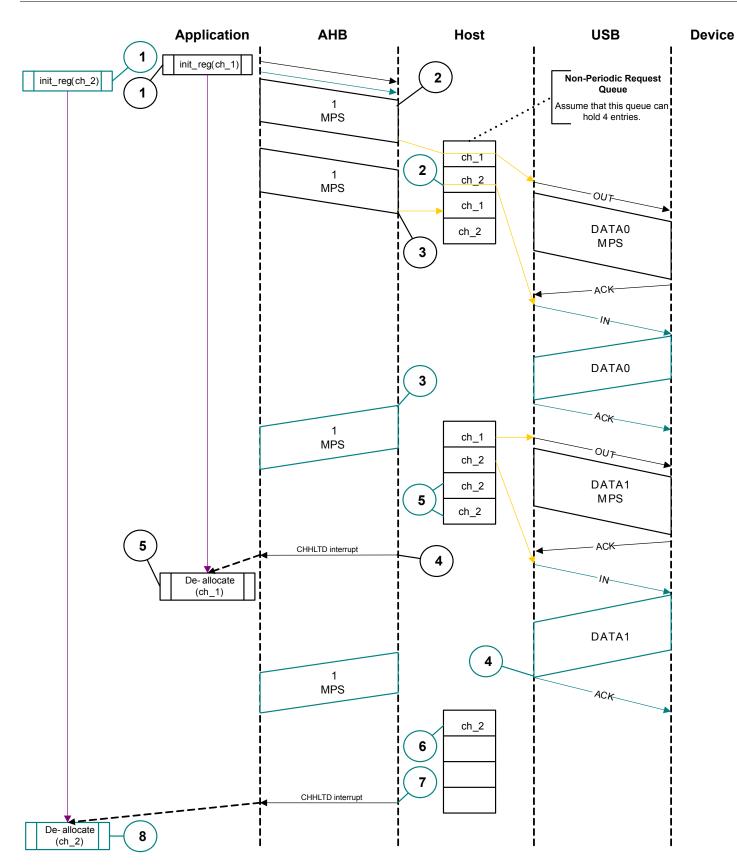

Figure 15.13. Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in DMA Mode

# 15.4.3.6.7.4 Handling Interrupts

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in DMA mode is shown in the following code samples.

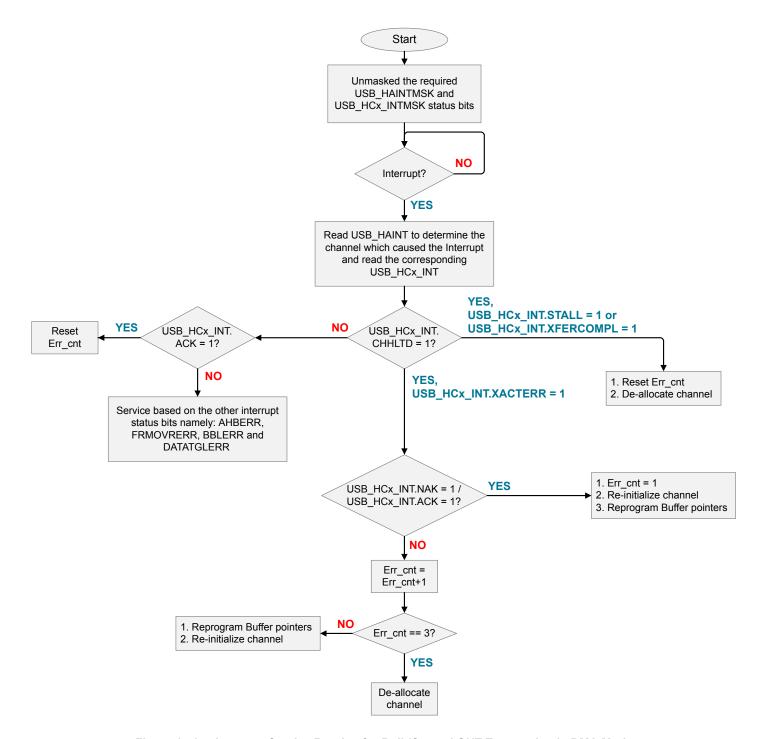

Figure 15.14. Interrupt Service Routine for Bulk/Control OUT Transaction in DMA Mode

In the previous figure, the Interrupt Service Routine is not required to handle NAK responses. This is the difference of proposed flow with respect to current flow. Similar flow is applicable for Control flow also.

The NAK status bits in USB\_HCx\_INT registers are updated. The application can unmask these interrupts when it requires the core to generate an interrupt for NAK. The NAK status is updated because during Xact\_err scenarios, this status provides a means for the application to determine whether the Xact\_err occurred three times consecutively or there were NAK responses in between two Xact\_err. This provides a mechanism for the application to reset the error counter accordingly. The application must read the NAK/ACK along with the xact\_err. If NAK/ACK is not set, the Xact\_err count must be incremented otherwise application must initialize the Xact\_err count to 1.

```
Unmask (CHHLTD)
if (CHHLTD)
   if (XFERCOMPL or STALL)
      Reset Error Count (Error_count=1)
      Mask ACK
      De-allocate Channel
   else if (XACTERR)
      if (NAK/ACK)
         Error_count = 1
         Re-initialize Channel
         Rewind Buffer Pointers
      else
         Error_count = Error_count + 1
         if (Error_count == 3)
            De allocate channel
         else
            Re-initialize Channel
            Rewind Buffer Pointers
else if (ACK)
   Reset Error Count (Error_count=1)
  Mask ACK
```

As soon as the channel is enabled, the core attempts to fetch and write data packets, in multiples of the maximum packet size, to the transmit FIFO when space is available in the transmit FIFO and the Request queue. The core stops fetching as soon as the last packet is fetched.

## 15.4.3.6.8 Bulk and Control IN Transactions in DMA Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization.

A typical bulk or control IN operation in DMA mode is shown in Figure 15.13 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in DMA Mode on page 352. See channel 2 (ch\_2).

The assumptions are:

- 1. The application is attempting to receive two maximum-packet-size packets (transfer size = 1,024 bytes).
- 2. The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (72 bytes for FS).
- 3. The Non-periodic Request Queue depth = 4.

# 15.4.3.6.8.1 Normal Bulk and Control IN Operations

The sequence of operations in Figure 15.13 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in DMA Mode on page 352 is as follows:

- 1. Initialize and enable channel 2 as explained in 15.4.3.1 Channel Initialization.
- 2. The host writes an IN request to the Request queue as soon as channel 2 receives the grant from the arbiter. (Arbitration is performed in a round-robin fashion, with fairness.).
- 3. The host starts writing the received data to the system memory as soon as the last byte is received with no errors.
- 4. When the last packet is received, the host sets an internal flag to remove any extra IN requests from the Request queue.
- 5. The host flushes the extra requests.
- 6. The final request to disable channel 2 is written to the Request queue. At this point, channel 2 is internally masked for further arbitration.
- 7. The host generates the CHHLTD interrupt as soon as the disable request comes to the top of the queue.
- 8. In response to the CHHLTD interrupt, de-allocate the channel for other transfers.

#### 15.4.3.6.8.2 Handling Interrupts

The channel-specific interrupt service routine for bulk and control IN transactions in DMA mode is shown in the following flow:

```
Unmask (CHHLTD)
if (CHHLTD)
   if (XFERCOMPL or STALL or BBLERR)
      Reset Error Count Mask ACK De-allocate Channel
   else if (XACTERR)
      if (Error_count == 2)
         De-allocate Channel
      else
         Unmask ACK
         Unmask NAK
         Unmask DATATGLERR
         Increment Error
         Count Re-initialize Channel
   }
else if (ACK or NAK or DATATGLERR)
   Reset Error Count
  Mask ACK
   Mask NAK
   Mask DATATGLERR
```

## 15.4.3.6.9 Interrupt OUT Transactions in Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization. See Figure 15.10 Transmit FIFO Write Task in Slave Mode on page 343 and Figure 15.11 Receive FIFO Read Task in Slave Mode on page 344 for read or write data to and from the FIFO in Slave mode.

A typical interrupt OUT operation in Slave mode is shown in Figure 15.15 Normal Interrupt OUT/IN Transactions in Slave Mode on page 357. See channel 1 (ch. 1). The assumptions are:

- The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet.
- · Periodic Request Queue depth = 4.

## 15.4.3.6.9.1 Normal Interrupt OUT Operation

The sequence of operations in Figure 15.15 Normal Interrupt OUT/IN Transactions in Slave Mode on page 357 is as follows:

- 1. Initialize and enable channel 1 as explained in 15.4.3.1 Channel Initialization. The application must set the USB HC1 CHAR.ODDFRM bit.
- 2. Write the first packet for channel 1. For a high-bandwidth interrupt transfer, the application must write the subsequent packets up to MC (maximum number of packets to be transmitted in the next frame times before switching to another channel).
- 3. Along with the last DWORD write of each packet, the host writes an entry to the Periodic Request Queue.
- 4. The host attempts to send an OUT token in the next (odd) frame.
- 5. The host generates an XFERCOMPL interrupt as soon as the last packet is transmitted successfully.
- 6. In response to the XFERCOMPL interrupt, reinitialize the channel for the next transfer.

## 15.4.3.6.9.2 Handling Interrupts

The channel-specific interrupt service routine for Interrupt OUT transactions in Slave mode is shown in the following flow:

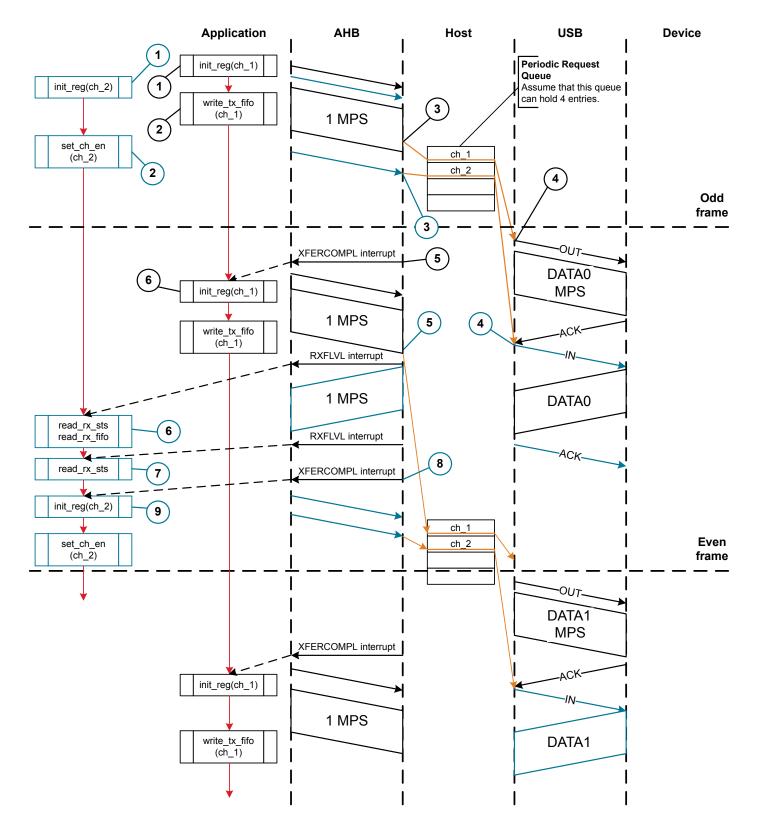

Figure 15.15. Normal Interrupt OUT/IN Transactions in Slave Mode

```
Unmask (NAK/XACTERR/STALL/XFERCOMPL/FRMOVRUN)
if (XFERCOMPL)
{
```

```
Reset Error Count
   Mask ACK
   De-allocate Channel
else if (STALL or FRMOVRUN)
   Mask ACK
   Unmask CHHLTD
   Disable Channel
   if (STALL)
      Transfer Done = 1
else if (NAK or XACTERR)
   Rewind Buffer Pointers
   Reset Error Count
   Mask ACK
   Unmask CHHLTD
   Disable Channel
else if (CHHLTD)
{
   Mask CHHLTD
   if (Transfer Done or (Error_count == 3))
      De-allocate Channel
   else
      Re-initialize Channel (in next b_interval - 1 Frame)
else if (ACK)
   Reset Error Count
   Mask ACK
```

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the Request queue up to the count specified in the MC field before switching to another channel. The application uses the USB GINTSTS.NPTXFEMP interrupt to find the transmit FIFO space.

### 15.4.3.6.10 Interrupt IN Transactions in Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization. See Figure 15.10 Transmit FIFO Write Task in Slave Mode on page 343 and Figure 15.11 Receive FIFO Read Task in Slave Mode on page 344 for read or write data to and from the FIFO in Slave mode.

A typical interrupt-IN operation in Slave mode is shown in Figure 15.15 Normal Interrupt OUT/IN Transactions in Slave Mode on page 357. See channel 2 (ch\_2). The assumptions are:

- 1. The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd. (transfer size = 1,024 bytes).
- 2. The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (1,031 bytes for FS).
- 3. Periodic Request Queue depth = 4.

### 15.4.3.6.10.1 Normal Interrupt IN Operation

The sequence of operations in Figure 15.15 Normal Interrupt OUT/IN Transactions in Slave Mode on page 357 (channel 2) is as follows:

- 1. Initialize channel 2 as explained in 15.4.3.1 Channel Initialization. The application must set the USB\_HC2\_CHAR.ODDFRM bit.
- 2. Set the USB\_HC2\_CHAR.CHENA bit to write an IN request to the Periodic Request Queue. For a high-bandwidth interrupt transfer, the application must write the USB\_HC2\_CHAR register MC (maximum number of expected packets in the next frame) times before switching to another channel.
- 3. The host writes an IN request to the Periodic Request Queue for each USB\_HC2\_CHAR register write with a CHENA bit set.
- 4. The host attempts to send an IN token in the next (odd) frame.
- 5. As soon as the IN packet is received and written to the receive FIFO, the host generates an RXFLVL interrupt.
- 6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
- 7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (USB\_GRXSTSR.PKTSTS != 0b0010).
- 8. The core generates an XFERCOMPL interrupt as soon as the receive packet status is read.
- 9. In response to the XFERCOMPL interrupt, read the USB\_HC2\_TSIZ.PKTCNT field. If USB\_HC2\_TSIZ.PKTCNT != 0, disable the channel (as explained in 15.4.3.2 Halting a Channel) before re-initializing the channel for the next transfer, if any). If USB\_HC2\_TSIZ.PKTCNT == 0, reinitialize the channel for the next transfer. This time, the application must reset the USB\_HC2\_CHAR.ODDFRM bit.

## 15.4.3.6.10.2 Handling Interrupts

The channel-specific interrupt service routine for an interrupt IN transaction in Slave mode is a follows.

```
Unmask (NAK/XACTERR/XFERCOMPL/BBLERR/STALL/FRMOVRUN/DATATGLERR)
if (XFERCOMPL)
{
   Reset Error Count
   Mask ACK
   if (USB_HCx_TSIZ.PKTCNT == 0)
      De-allocate Channel
   else
      Transfer Done = 1
      Unmask CHHLTD
      Disable Channel
else if (STALL or FRMOVRUN or NAK or DATATGLERR or BBLERR)
   Mask ACK
   Unmask CHHLTD
   Disable Channel
   if (STALL or BBLERR)
      Reset Error Count
      Transfer Done = 1
   else if (!FRMOVRUN)
      Reset Error Count
else if (XACTERR)
   Increment Error Count
   Unmask ACK
   Unmask CHHLTD
   Disable Channel
else if (CHHLTD)
   Mask CHHLTD
   if (Transfer Done or (Error_count == 3))
      De-allocate Channel
   else
      Re-initialize Channel (in next b_interval - 1 Frame)
else if (ACK)
   Reset Error Count
   Mask ACK
```

The application is expected to write the requests for the same channel when the Request queue space is available up to the count specified in the MC field before switching to another channel (if any).

## 15.4.3.6.11 Interrupt OUT Transactions in DMA Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization.

A typical interrupt OUT operation in DMA mode is shown in Figure 15.16 Normal Interrupt OUT/IN Transactions in DMA Mode on page 363. See channel 1 (ch\_1). The assumptions are:

- The application is attempting to transmit one packet in every frame (up to 1 maximum packet size of 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet (1 KB for FS).
- Periodic Request Queue depth = 4.

## 15.4.3.6.11.1 Normal Interrupt OUT Operation

- 1. Initialize and enable channel 1 as explained in 15.4.3.1 Channel Initialization.
- 2. The host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last DWORD fetch. In high-bandwidth transfers, the host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
- 3. The host attempts to send the OUT token in the beginning of the next odd frame.
- 4. After successfully transmitting the packet, the host generates a CHHLTD interrupt.
- 5. In response to the CHHLTD interrupt, reinitialize the channel for the next transfer.

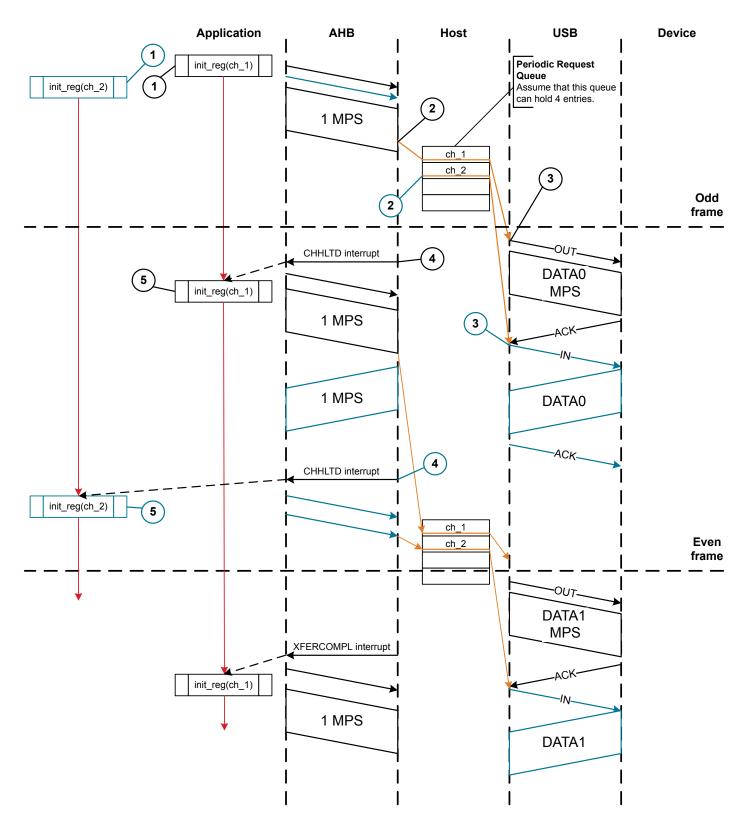

Figure 15.16. Normal Interrupt OUT/IN Transactions in DMA Mode

## 15.4.3.6.11.2 Handling Interrupts

The following code sample shows the channel-specific ISR for an interrupt OUT transaction in DMA mode.

```
Unmask (CHHLTD)
if (CHHLTD)
{
   if (XFERCOMPL)
   {
      Reset Error Count
      Mask ACK
      if (Transfer Done)
         De-allocate Channel
      else
         Re-initialize Channel (in next b_interval - 1 Frame)
   else if (STALL)
      Transfer Done = 1
      Reset Error Count
      Mask ACK
      De-allocate Channel
   else if (NAK or FRMOVRUN)
      Mask ACK
      Rewind Buffer Pointers
      Re-initialize Channel (in next b_interval - 1 Frame)
      if (NAK)
         Reset Error Count
   else if (XACTERR)
      if (Error_count == 2)
         De-allocate Channel
      else
         Increment Error Count
         Rewind Buffer Pointers
         Unmask ACK
         Re-initialize Channel (in next b_interval - 1 Frame)
else if (ACK)
   Reset Error Count
   Mask ACK
```

As soon as the channel is enabled, the core attempts to fetch and write data packets, in maximum packet size multiples, to the transmit FIFO when the space is available in the transmit FIFO and the Request queue. The core stops fetching as soon as the last packet is fetched (the number of packets is determined by the MC field of the USB\_HCx\_CHAR register).

### 15.4.3.6.12 Interrupt IN Transactions in DMA Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization.

A typical interrupt IN operation in DMA mode is shown in Figure 15.16 Normal Interrupt OUT/IN Transactions in DMA Mode on page 363. See channel 2 (ch. 2). The assumptions are:

- · The application is attempting to receive one packet in every frame (up to 1 maximum packet size of 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (1,032 bytes for FS).
- Periodic Request Queue depth = 4.

#### 15.4.3.6.12.1 Normal Interrupt IN Operation

The sequence of operations in Figure 15.16 Normal Interrupt OUT/IN Transactions in DMA Mode on page 363 (channel 2) is as follows:

- 1. Initialize and enable channel 2 as explained in 15.4.3.1 Channel Initialization.
- 2. The host writes an IN request to the Request queue as soon as the channel 2 gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the host writes consecutive writes up to MC times.
- 3. The host attempts to send an IN token at the beginning of the next (odd) frame.
- 4. As soon the packet is received and written to the receive FIFO, the host generates a CHHLTD interrupt.
- 5. In response to the CHHLTD interrupt, reinitialize the channel for the next transfer.

### 15.4.3.6.12.2 Handling Interrupts

The channel-specific interrupt service routine for Interrupt IN transactions in DMA mode is as follows.

```
Unmask (CHHLTD)
if (CHHLTD)
{
   if (XFERCOMPL)
      Reset Error Count
      Mask ACK
      if (Transfer Done)
         De-allocate Channel
      else
         Re-initialize Channel (in next b_interval - 1 Frame)
   else if (STALL or BBLERR)
      Reset Error Count
      Mask ACK
      De-allocate Channel
   else if (NAK or DATATGLERR or FRMOVRUN)
      Mask ACK
      Re-initialize Channel (in next b_interval - 1 Frame)
      if (DATATGLERR or NAK)
         Reset Error Count
   else if (XACTERR)
      if (Error_count == 2)
         De-allocate Channel
      else
         Increment Error Count
         Unmask ACK
         Re-initialize Channel (in next b_interval - 1 Frame)
else if (ACK)
   Reset Error Count
   Mask ACK
```

As soon as the channel is enabled, the core attempts to write the requests into the Request queue when the space is available up to the count specified in the MC field.

#### 15.4.3.6.13 Isochronous OUT Transactions in Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization. See Figure 15.10 Transmit FIFO Write Task in Slave Mode on page 343 and Figure 15.11 Receive FIFO Read Task in Slave Mode on page 344 for read or write data to and from the FIFO in Slave mode.

A typical isochronous OUT operation in Slave mode is shown in Figure 15.17 Normal Isochronous OUT/IN Transactions in Slave Mode on page 368. See channel 1 (ch. 1). The assumptions are:

- The application is attempting to send one packet every frame (up to 1 maximum packet size), starting with an odd frame. (transfer size = 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet (1 KB).
- Periodic Request Queue depth = 4.

#### 15.4.3.6.13.1 Normal Isochronous OUT Operation

The sequence of operations in Figure 15.18 Normal Isochronous OUT/IN Transactions in DMA Mode on page 371 (channel 1) is as follows:

- 1. Initialize and enable channel 1 as explained in 15.4.3.1 Channel Initialization. The application must set the USB\_HC1\_CHAR.ODDFRM bit.
- 2. Write the first packet for channel 1. For a high-bandwidth isochronous transfer, the application must write the subsequent packets up to MC (maximum number of packets to be transmitted in the next frame) times before switching to another channel.
- 3. Along with the last DWORD write of each packet, the host writes an entry to the Periodic Request Queue.
- 4. The host attempts to send the OUT token in the next frame (odd).
- 5. The host generates the XFERCOMPL interrupt as soon as the last packet is transmitted successfully.
- 6. In response to the XFERCOMPL interrupt, reinitialize the channel for the next transfer.

### 15.4.3.6.13.2 Handling Interrupts

The channel-specific interrupt service routine for isochronous OUT transactions in Slave mode is shown in the following flow:

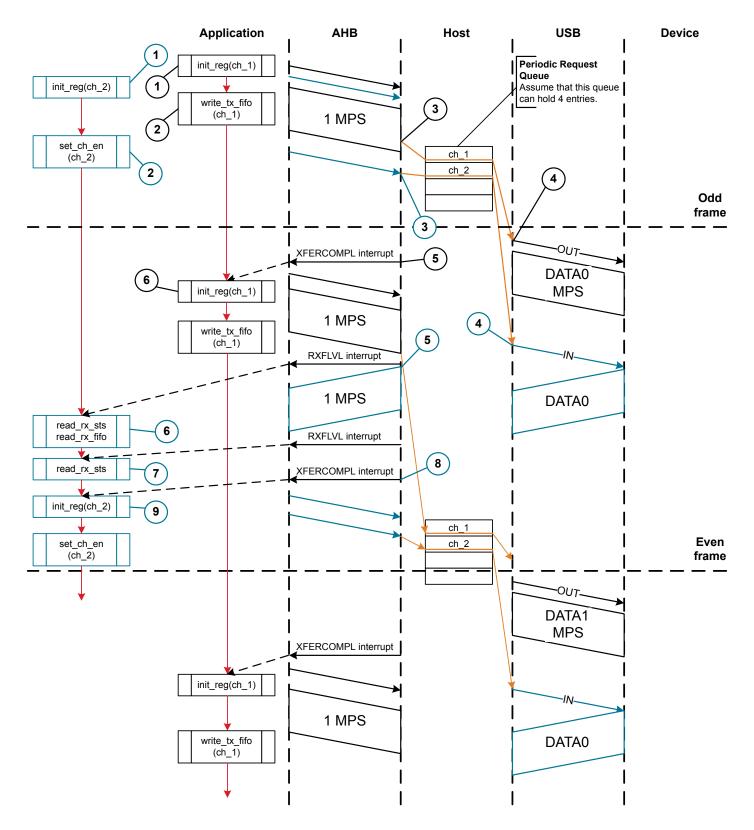

Figure 15.17. Normal Isochronous OUT/IN Transactions in Slave Mode

```
Unmask (FRMOVRUN/XFERCOMPL)
if (XFERCOMPL)
{
```

```
De-allocate Channel
}
else if (FRMOVRUN)
{
    Unmask CHHLTD
    Disable Channel
}
else if (CHHLTD)
{
    Mask CHHLTD
    De-allocate Channel
}
```

#### 15.4.3.6.14 Isochronous IN Transactions in Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization. See Figure 15.10 Transmit FIFO Write Task in Slave Mode on page 343 and Figure 15.11 Receive FIFO Read Task in Slave Mode on page 344 for read or write data to and from the FIFO in Slave mode.

A typical isochronous IN operation in Slave mode is shown in Figure 15.17 Normal Isochronous OUT/IN Transactions in Slave Mode on page 368. See channel 2 (ch\_2). The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame. (transfer size = 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (1,031 bytes for FS).
- · Periodic Request Queue depth = 4.

#### 15.4.3.6.14.1 Normal Isochronous IN Operation

The sequence of operations in Figure 15.17 Normal Isochronous OUT/IN Transactions in Slave Mode on page 368 (channel 2) is as follows:

- 1. Initialize channel 2 as explained in 15.4.3.1 Channel Initialization. The application must set the USB HC2 CHAR.ODDFRM bit.
- 2. Set the USB\_HC2\_CHAR.CHENA bit to write an IN request to the Periodic Request Queue. For a high-bandwidth isochronous transfer, the application must write the USB\_HC2\_CHAR register MC (maximum number of expected packets in the next frame) times before switching to another channel.
- 3. The host writes an IN request to the Periodic Request Queue for each USB\_HC2\_CHAR register write with the CHENA bit set.
- The host attempts to send an IN token in the next odd frame.
- 5. As soon as the IN packet is received and written to the receive FIFO, the host generates an RXFLVL interrupt.
- 6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
- 7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (USB\_GRXSTSR.PKTSTS != 0b0010).
- 8. The core generates an XFERCOMPL interrupt as soon as the receive packet status is read.
- 9. In response to the XFERCOMPL interrupt, read the USB\_HC2\_TSIZ.PKTCNT field. If USB\_HC2\_TSIZ.PKTCNT != 0, disable the channel (as explained in 15.4.3.2 Halting a Channel) before re-initializing the channel for the next transfer, if any. If USB\_HC2\_TSIZ.PKTCNT == 0, reinitialize the channel for the next transfer. This time, the application must reset the USB\_HC2\_CHAR.ODDFRM bit.

#### 15.4.3.6.14.2 Handling Interrupts

The channel-specific interrupt service routine for an isochronous IN transaction in Slave mode is as follows.

```
Unmask (XACTERR/XFERCOMPL/FRMOVRUN/BBLERR)
if (XFERCOMPL or FRMOVRUN)
{
   if (XFERCOMPL and (USB_HCx_TSIZ.PKTCNT == 0))
      Reset Error Count
      De-allocate Channel
   else
      Unmask CHHLTD
      Disable Channel
else if (XACTERR or BBLERR)
   Increment Error Count
   Unmask CHHLTD
   Disable Channel
else if (CHHLTD)
   Mask CHHLTD
   if (Transfer Done or (Error_count == 3))
      De-allocate Channel
   else
      Re-initialize Channel
```

### 15.4.3.6.15 Isochronous OUT Transactions in DMA Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization.

A typical isochronous OUT operation in DMA mode is shown in Figure 15.18 Normal Isochronous OUT/IN Transactions in DMA Mode on page 371. See channel 1 (ch. 1). The assumptions are:

- The application is attempting to transmit one packet every frame (up to 1 maximum packet size of 1,024 bytes).
- · The Periodic Transmit FIFO can hold one packet (1 KB).
- Periodic Request Queue depth = 4.

#### 15.4.3.6.15.1 Normal Isochronous OUT Operation

- 1. Initialize and enable channel 1 as explained in 15.4.3.1 Channel Initialization.
- 2. The host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last DWORD fetch. In high-bandwidth transfers, the host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
- 3. The host attempts to send an OUT token in the beginning of the next (odd) frame.
- 4. After successfully transmitting the packet, the host generates a CHHLTD interrupt.
- 5. In response to the CHHLTD interrupt, reinitialize the channel for the next transfer.

## 15.4.3.6.15.2 Handling Interrupts

The channel-specific interrupt service routine for Isochronous OUT transactions in DMA mode is shown in the following flow:

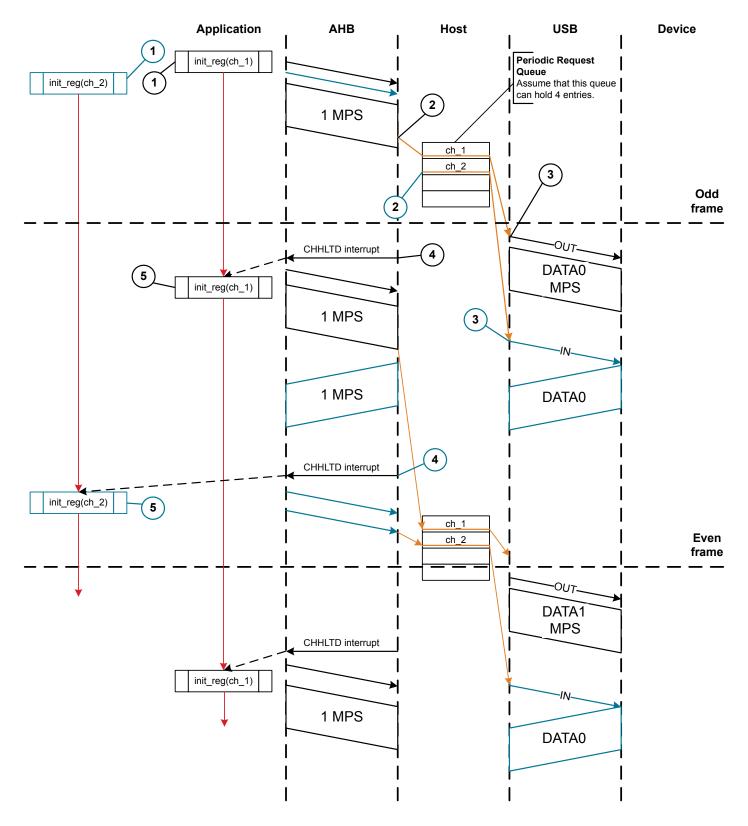

Figure 15.18. Normal Isochronous OUT/IN Transactions in DMA Mode

```
Unmask (CHHLTD)
if (CHHLTD)
{
```

```
if (XFERCOMPL or FRMOVRUN)
{
    De-allocate Channel
}
```

#### 15.4.3.6.16 Isochronous IN Transactions in DMA Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the connected device, it must initialize a channel as described in 15.4.3.1 Channel Initialization.

A typical isochronous IN operation in DMA mode is shown in Figure 15.18 Normal Isochronous OUT/IN Transactions in DMA Mode on page 371. See channel 2 (ch. 2). The assumptions are:

- The application is attempting to receive one packet in every frame (up to 1 maximum packet size of 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDS per packet (1,031 bytes).
- · Periodic Request Queue depth = 4.

#### 15.4.3.6.16.1 Normal Isochronous IN Operation

The sequence of operations in Figure 15.18 Normal Isochronous OUT/IN Transactions in DMA Mode on page 371 (channel 2) is as follows:

- 1. Initialize and enable channel 2 as explained in 15.4.3.1 Channel Initialization.
- 2. The host writes an IN request to the Request queue as soon as the channel 2 gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the host performs consecutive writes up to MC times.
- 3. The host attempts to send an IN token at the beginning of the next (odd) frame.
- 4. As soon the packet is received and written to the receive FIFO, the host generates a CHHLTD interrupt.
- 5. In response to the CHHLTD interrupt, reinitialize the channel for the next transfer.

### 15.4.3.6.16.2 Handling Interrupts

The channel-specific interrupt service routine for an isochronous IN transaction in DMA mode is as follows.

```
Unmask (CHHLTD)
if (CHHLTD)
{
    if (XFERCOMPL or FRMOVRUN)
    {
        if (XFERCOMPL and (USB_HCx_TSIZ.PKTCNT == 0))
        {
            Reset Error Count
            De-allocate Channel
        }
        else
        {
            De-allocate Channel
        }
    }
    else if (XACTERR or BBLERR)
    {
        if (Error_count == 2)
        {
            De-allocate Channel
        }
        else
        {
            Increment Error Count
            Re-enable Channel (in next b_interval - 1 Frame)
        }
    }
}
```

### 15.4.4 Device Programming Model

Before you program the Device, be sure to read 15.4.1 Overview: Programming the Core and 15.4.2 Modes of Operation.

#### 15.4.4.1 Endpoint Initialization

This section addresses the following topics:

- 15.4.4.1.1 Initialization on USB Reset
- 15.4.4.1.2 Initialization on Enumeration Completion
- 15.4.4.1.3 Initialization on SetAddress Command
- 15.4.4.1.4 Initialization on SetConfiguration/SetInterface Command
- 15.4.4.1.5 Endpoint Activation
- 15.4.4.1.6 Endpoint Deactivation
- 15.4.4.1.7 Device DMA/Slave Mode Initialization

#### 15.4.4.1.1 Initialization on USB Reset

- 1. Set the NAK bit for all OUT endpoints
  - USB DOEPx CTL.SNAK = 1 (for all OUT endpoints)
- 2. Unmask the following interrupt bits:
  - USB USB DAINTMSK.INEP0 = 1 (control 0 IN endpoint)
  - USB USB DAINTMSK.OUTEP0 = 1 (control 0 OUT endpoint)
  - USB DOEPMSK.SETUP = 1
  - USB DOEPMSK.XFERCOMPL = 1
  - USB\_DIEPMSK.XFERCOMPL = 1
  - USB\_DIEPMSK.TIMEOUTMSK = 1
- To transmit or receive data, the device must initialize more registers as specified in 15.4.4.1.7 Device DMA/Slave Mode Initialization.
- Set up the Data FIFO RAM for each of the FIFOs
  - Program the USB\_GRXFSIZ Register, to be able to receive control OUT data and setup data. At a minimum, this must be equal
    to 1 max packet size of control endpoint 0 + 2 DWORDs (for the status of the control OUT data packet) + 10 DWORDs (for
    setup packets).
  - Program the Device IN Endpoint Transmit FIFO size register (depending on the FIFO number chosen), to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
- 5. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
  - USB DOEP0TSIZ.SUPCNT = 3 (to receive up to 3 back-to-back SETUP packets)
  - · In DMA mode, USB DOEP0DMAADDR register with a memory address to store any SETUP packets received

At this point, all initialization required to receive SETUP packets is done, except for enabling control OUT endpoint 0 in DMA mode.

#### 15.4.4.1.2 Initialization on Enumeration Completion

- 1. On the Enumeration Done interrupt (USB\_GINTSTS.ENUMDONE), read the USB\_DSTS register to determine the enumeration speed.
- Program the USB\_DIEPOCTL.MPS field to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
- 3. In DMA mode, program the USB\_DOEP0CTL register to enable control OUT endpoint 0, to receive a SETUP packet.
  - USB DOEP0CTL.EPENA = 1

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

### 15.4.4.1.3 Initialization on SetAddress Command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

- 1. Program the USB DCFG register with the device address received in the SetAddress command.
- 2. Program the core to send out a status IN packet.

### 15.4.4.1.4 Initialization on SetConfiguration/SetInterface Command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

- 1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
- 2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
- 3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
- 4. For details on a particular endpoint's activation or deactivation, see 15.4.4.1.5 Endpoint Activation and 15.4.4.1.6 Endpoint Deactivation.
- 5. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the USB\_USB\_DAINTMSK register.
- 6. Set up the Data FIFO RAM for each FIFO. See 15.4.7.1 Data FIFO RAM Allocation for more detail.
- 7. After all required endpoints are configured, the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

#### 15.4.4.1.5 Endpoint Activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

- 1. Program the characteristics of the required endpoint into the following fields of the USB\_DIEPx\_CTL register (for IN or bidirectional endpoints) or the USB\_DOEPx\_CTL register (for OUT or bidirectional endpoints).
  - · Maximum Packet Size
  - USB Active Endpoint = 1
  - Endpoint Start Data Toggle (for interrupt and bulk endpoints)
  - Endpoint Type
  - · TxFIFO Number
- Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

### 15.4.4.1.6 Endpoint Deactivation

This section describes the steps required to deactivate an existing endpoint.

- 1. In the endpoint to be deactivated, clear the USB Active Endpoint bit in the USB\_DIEPx\_CTL register (for IN or bidirectional endpoints) or the USB\_DOEPx\_CTL register (for OUT or bidirectional endpoints).
- 2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, resulting in a timeout on the USB.

## 15.4.4.1.7 Device DMA/Slave Mode Initialization

The application must meed the following conditions to set up the device core to handle traffic.

- In Slave mode, USB\_GINTMSK.NPTXFEMPMSK, and USB\_GINTMSK.RXFLVLMSK must be unset.
- In DMA mode, the aforementioned interrupts must be masked.

#### 15.4.4.1.8 Transfer Stop Process

When the core is operating as a device, use the following programing sequence if you want to stop any transfers (because of an interrupt from the host, typically a reset).

# 15.4.4.1.8.1 Transfer Stop Programming Flow for IN Endpoints

### Sequence of operations:

- 1. Disable the IN endpoint by programming USB DIEP0CTL/USB DIEPx CTL.EPDIS = 1.
- 2. Wait for the USB\_DIEPx\_INT.EPDISBLD interrupt, which indicates that the IN endpoint is completely disabled. When the EP-DISBLD interrupt is asserted, the core clears the following bits:
  - USB DIEPOCTL/USB DIEPx CTL.EPDIS = 0
  - USB\_DIEPOCTL/USB\_DIEPx\_CTL.EPENA = 0
- 3. Flush the TX FIFO by programming the following bits:
  - USB GRSTCTL.TXFFLSH = 1
  - USB GRSTCTL.TXFNUM = FIFO number specific to endpoint
- 4. The application can start polling till USB\_GRSTCTL.TXFFLSH is cleared. When this bit is cleared, it ensures that there is no data left in the TX FIFO.

### 15.4.4.1.8.2 Transfer Stop Programming Flow for OUT Endpoints

#### Sequence of operations:

- 1. Enable all OUT endpoints by setting USB\_DOEP0CTL/USB\_DOEPx\_CTL.EPENA = 1.
- 2. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in 15.4.4.2.2.5 Setting the Global OUT NAK. This ensures that data in the RX FIFO is sent to the application successfully. Set USB\_DCTL.USB\_DCTL.SGOUTNAK = 1.
- Wait for the USB\_GINTSTS.GOUTNAKEFF interrupt.
- 4. Disable all active OUT endpoints by programming the following register bits:
  - USB DOEP0CTL/USB DOEPx CTL.EPENA = 1
  - USB\_DOEP0CTL/USB\_DOEPx\_CTL.EPDIS = 1
  - USB DOEP0CTL/USB DOEPx CTL.SNAK = 1
- 5. Wait for the USB\_DOEP0INT/USB\_DOEPx\_INT.EPDISBLD interrupt for each OUT endpoint programmed in the previous step. The USB\_DOEP0INT/USB\_DOEPx\_INT.EPDISBLD interrupt indicates that the corresponding OUT endpoint is completely disabled. When the EPDISBLD interrupt is asserted, the core clears the following bits:
  - USB DOEP0CTL/USB DOEPx CTL.EPENA = 0
  - USB\_DOEP0CTL/USB\_DOEPx\_CTL.EPDIS = 0

**Note:** The application must not flush the Rx FIFO, as the Global OUT NAK effective interrupt earlier ensures that there is no data left in the Rx FIFO.

### 15.4.4.2 Device Programming Operations

The table below provides links to the programming sequence for different USB transaction types.

**Table 15.2. Transaction Programming Sequences** 

Device Mode	IN	SETUP	OUT
Control			
Slave	15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode	15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes	15.4.4.2.2.8 Generic Non-Iso- chronous OUT Data Transfers in DMA and Slave Modes
DMA	15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode	15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes	15.4.4.2.2.8 Generic Non-Iso- chronous OUT Data Transfers in DMA and Slave Modes
Bulk			
Slave	15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode		15.4.4.2.2.8 Generic Non-Iso- chronous OUT Data Transfers in DMA and Slave Modes
DMA	15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode	_	15.4.4.2.2.8 Generic Non-Iso- chronous OUT Data Transfers in DMA and Slave Modes
Interrupt			
Slave	15.4.4.2.3.13 Generic Periodic IN (Interrupt and Isochronous) Data Transfers and 15.4.4.2.3.14 Generic Periodic IN Data Transfers Using the Periodic Transfer Interrupt Feature		15.4.4.2.2.8 Generic Non-Iso- chronous OUT Data Transfers in DMA and Slave Modes and 15.4.4.2.2.10 Generic Interrupt OUT Data Transfers Using Peri- odic Transfer Interrupt Feature
DMA	15.4.4.2.3.13 Generic Periodic IN (Interrupt and Isochronous) Data Transfers and 15.4.4.2.3.14 Generic Periodic IN Data Transfers Using the Periodic Transfer Interrupt Feature		15.4.4.2.2.8 Generic Non-Iso- chronous OUT Data Transfers in DMA and Slave Modes and 15.4.4.2.2.10 Generic Interrupt OUT Data Transfers Using Peri- odic Transfer Interrupt Feature
Isochronous			
Slave	15.4.4.2.3.13 Generic Periodic IN (Interrupt and Isochronous) Data Transfers	_	15.4.4.2.2.2 Control Read Transfers (SETUP, Data IN, Status OUT) and 15.4.4.2.2.12 Incomplete Iso- chronous OUT Data Transfers in DMA and Slave Modes
DMA	15.4.4.2.3.13 Generic Periodic IN (Interrupt and Isochronous) Data Transfers and 15.4.4.2.3.14 Generic Periodic IN Data Transfers Using the Periodic Transfer Interrupt Feature	_	15.4.4.2.2.2 Control Read Transfers (SETUP, Data IN, Status OUT) and 15.4.4.2.2.12 Incomplete Iso- chronous OUT Data Transfers in DMA and Slave Modes

### 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes

This section describes the internal data flow and application-level operations during data OUT transfers and setup transactions.

#### 15.4.4.2.1.1 Control Setup Transactions

This section describes how the core handles SETUP packets and the application's sequence for handling setup transactions. To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. See 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.

### **Application Requirements**

- 1. To receive a SETUP packet, the USB\_DOEPx\_TSIZ.SUPCNT field in a control OUT endpoint must be programmed to a non-zero value. When the application programs the SUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the USB\_DOEPx\_CTL.NAK status and USB\_DOEPx\_CTL.EPENA bit setting. The SUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the SUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the SUPCNT field, but the application possibly is not be able to determine the correct number of SETUP packets received in the Setup stage of a control transfer.
  - USB\_DOEPx\_TSIZ.SUPCNT = 3
- 2. In DMA mode, the OUT endpoint must also be enabled, to transfer the received SETUP packet data from the internal receive FIFO to the external memory.
  - USB DOEPx CTL.EPENA = 1
- 3. The application must always allocate some extra space in the Receive Data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
  - The space to be Reserved is (4 \* n) + 6 DWORDs, where n is the number of control endpoints supported by the device. Three DWORDs are required for the first SETUP packet, 1 DWORD is required for the Setup Stage Done DWORD, and 6 DWORDs are required to store two extra SETUP packets among all control endpoints.
  - 3 DWORDs per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (Setup Packet Pattern). The core reserves this space in the receive data.
  - FIFO to write SETUP data only, and never uses this space for data packets.
- 4. In Slave mode, the application must read the 2 DWORDs of the SETUP packet from the receive FIFO. In DMA mode, the core writes the 2 DWORDs of SETUP data to the memory.
- 5. The application must read and discard the Setup Stage Done DWORD from the receive FIFO.

#### **Internal Data Flow**

- 1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and Stall bit settings.
  - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
- 2. For every SETUP packet received on the USB, 3 DWORDs of data is written to the receive FIFO, and the SUPCNT field is decremented by 1.
  - · The first DWORD contains control information used internally by the core
  - · The second DWORD contains the first 4 bytes of the SETUP command
  - · The third DWORD contains the last 4 bytes of the SETUP command
- 3. When the Setup stage changes to a Data IN/OUT stage, the core writes an entry (Setup Stage Done DWORD) to the receive FIFO, indicating the completion of the Setup stage.
- 4. On the AHB side, SETUP packets are emptied either by the DMA or the application. In DMA mode, the SETUP packets (2 DWORDs) are written to the memory location programmed in the USB\_DOEPx\_DMAADDR register, only if the endpoint is enabled. If the endpoint is not enabled, the data remains in the receive FIFO until the enable bit is set.
- 5. When either the DMA or the application pops the Setup Stage Done DWORD from the receive FIFO, the core interrupts the application with a USB\_DOEPx\_INT.SETUP interrupt, indicating it can process the received SETUP packet.
  - The core clears the endpoint enable bit for control OUT endpoints.

### **Application Programming Sequence**

- 1. Program the USB DOEPx TSIZ register.
  - USB DOEPx TSIZ.SUPCNT = 3
- 2. In DMA mode, program the USB\_DOEPx\_DMAADDR register and USB\_DOEPx\_CTL register with the endpoint characteristics and set the Endpoint Enable bit (USB\_DOEPx\_CTL.EPENA).
  - Endpoint Enable = 1
- 3. In Slave mode, wait for the USB\_GINTSTS.RXFLVL interrupt and empty the data packets from the receive FIFO, as explained in 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode. This step can be repeated many times.
- 4. Assertion of the USB DOEPx INT.SETUP interrupt marks a successful completion of the SETUP Data Transfer.
  - On this interrupt, the application must read the USB\_DOEPx\_TSIZ register to determine the number of SETUP packets received and process the last received SETUP packet.
  - In DMA mode, the application must also determine if the interrupt bit USB\_DOEPx\_INT.BACK2BACKSETUP is set. This bit is set if the core has received more than three back-to-back SETUP packets. If this is the case, the application must ignore the USB\_DOEPx\_TSIZ.SUPCNT value and use the USB\_DOEPx\_DMAADDR directly to read out the last SETUP packet received. USB\_DOEPx\_DMAADDR-8 provides the pointer to the last valid SETUP data.

**Note:** If the application has not enabled EP0 before the host sends the SETUP packet, the core ACKs the SETUP packet and stores it in the FIFO, but does not write to the memory until EP0 is enabled. When the application enables the EP0 (first enable) and clears the NAK bit at the same time the Host sends DATA OUT, the DATA OUT is stored in the RxFIFO. The OTG core then writes the setup data to the memory and disables the endpoint. Though the application expects a Transfer Complete interrupt for the Data OUT phase, this does not occur, because the SETUP packet, rather than the DATA OUT packet, enables EP0 the first time. Thus, the DATA OUT packet is still in the RxFIFO until the application re-enables EP0. The application must enable EP0 one more time for the core to process the DATA OUT packet.

The following figure charts this flow:

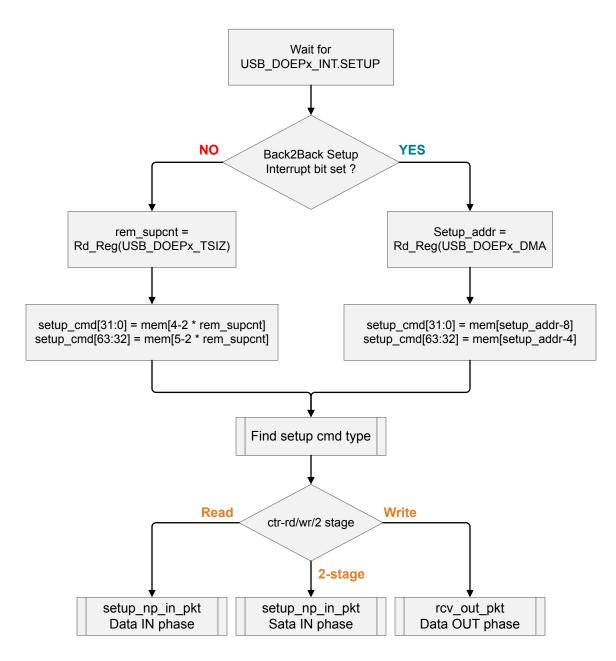

Figure 15.19. Processing a SETUP Packet

### 15.4.4.2.1.2 Handling More Than Three Back-to-Back SETUP Packets

Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the core generates an interrupt (USB\_DOEPx\_INT.BACK2BACKSETUP). In DMA mode, the core also rewinds the DMA address for that endpoint (USB\_DOEPx\_DMAADDR) and overwrites the first SETUP packet in system memory with the fourth, second with the fifth, and so on. If the BACK2BACKSETUP interrupt is asserted, the application must read the OUT endpoint DMA register (USB\_DOEPx\_DMAADDR) to determine the final SETUP data in system memory.

In DMA mode, the application can mask the BACK2BACKSETUP interrupt, but after receiving the DOEPINT.SETUP interrupt, the application can read the DOEPINT.BACK2BACKSETUP interrupt bit. In Slave mode, the application can use the USB\_GINTSTS.RXFLVL interrupt to read out the SETUP packets from the FIFO whenever the core receives the SETUP packet.

### 15.4.4.2.2 Control Transfers

This section describes the various types of control transfers.

#### 15.4.4.2.2.1 Control Write Transfers (SETUP, Data OUT, Status IN)

This section describes control write transfers.

### **Application Programming Sequence**

- 1. Assertion of the USB\_DOEPx\_INT.SETUP Packet interrupt indicates that a valid SETUP packet has been transferred to the application. See 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes for more details. At the end of the Setup stage, the application must reprogram the USB\_DOEPx\_TSIZ.SUPCNT field to 3 to receive the next SETUP packet.
- 2. If the last SETUP packet received before the assertion of the SETUP interrupt indicates a data OUT phase, program the core to perform a control OUT transfer as explained in 15.4.4.2.2.8 Generic Non-Isochronous OUT Data Transfers in DMA and Slave Modes. In DMA mode, the application must reprogram the USB\_DOEPx\_DMAADDR register to receive a control OUT data packet to a different memory location.
- 3. In a single OUT data transfer on control endpoint 0, the application can receive up to 64 bytes. If the application is expecting more than 64 bytes in the Data OUT stage, the application must re-enable the endpoint to receive another 64 bytes, and must continue to do so until it has received all the data in the Data stage.
- 4. Assertion of the USB\_DOEPx\_INT.Transfer Completed interrupt on the last data OUT transfer indicates the completion of the data OUT phase of the control transfer.
- 5. On completion of the data OUT phase, the application must do the following.
  - To transfer a new SETUP packet in DMA mode, the application must re-enable the control OUT endpoint as explained in 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes.
    - USB DOEPx CTL.EPENA = 1
  - To execute the received Setup command, the application must program the required registers in the core. This step is optional, based on the type of Setup command received.
- 6. For the status IN phase, the application must program the core as described in 15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode to perform a data IN transfer.
- Assertion of the USB\_DIEPx\_INT.XFERCOMPL interrupt indicates completion of the status IN phase of the control transfer.
- 8. The previous step must be repeated until the USB\_DIEPx\_INT.XFERCOMPL interrupt is detected on the endpoint, marking the completion of the control write transfer.

#### 15.4.4.2.2.2 Control Read Transfers (SETUP, Data IN, Status OUT)

This section describes control read transfers.

### **Application Programming Sequence**

- 1. Assertion of the USB\_DOEPx\_INT.SETUP Packet interrupt indicates that a valid SETUP packet has been transferred to the application. See 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes for more details. At the end of the Setup stage, the application must reprogram the USB\_DOEPx\_TSIZ.SUPCNT field to 3 to receive the next SETUP packet.
- 2. If the last SETUP packet received before the assertion of the SETUP interrupt indicates a data IN phase, program the core to perform a control IN transfer as explained in 15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode.
- 3. On a single IN data transfer on control endpoint 0, the application can transmit up to 64 bytes. To transmit more than 64 bytes in the Data IN stage, the application must re-enable the endpoint to transmit another 64 bytes, and must continue to do so, until it has transmitted all the data in the Data stage.
- 4. The previous step must be repeated until the USB\_DIEPx\_INT.XFERCOMPL interrupt is detected for every IN transfer on the end-point.
- 5. The USB\_DIEPx\_INT.XFERCOMPL interrupt on the last IN data transfer marks the completion of the control transfer's Data stage.
- 6. To perform a data OUT transfer in the status OUT phase, the application must program the core as described in 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes.
  - The application must program the USB\_DCFG.NZSTSOUTHSHK handshake field to a proper setting before transmitting an data OUT transfer for the Status stage.
  - In DMA mode, the application must reprogram the USB\_DOEPx\_DMAADDR register to receive the control OUT data packet to a different memory location.
- 7. Assertion of the USB\_DOEPx\_INT.XFERCOMPL interrupt indicates completion of the status OUT phase of the control transfer. This marks the successful completion of the control read transfer.
  - To transfer a new SETUP packet in DMA mode, the application must re-enable the control OUT endpoint as explained in 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes.
  - USB\_DOEPx\_CTL.EPENA = 1

### 15.4.4.2.2.3 Two-Stage Control Transfers (SETUP/Status IN)

This section describes two-stage control transfers.

### **Application Programming Sequence**

- 1. Assertion of the USB\_DOEPx\_INT.SETUP interrupt indicates that a valid SETUP packet has been transferred to the application. See 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes for more detail. To receive the next SETUP packet, the application must reprogram the USB\_DOEPx\_TSIZ.SUPCNT field to 3 at the end of the Setup stage.
- 2. Decode the last SETUP packet received before the assertion of the SETUP interrupt. If the packet indicates a two-stage control command, the application must do the following.
  - To transfer a new SETUP packet in DMA mode, the application must re-enable the control OUT endpoint. See 15.4.4.2.1 OUT Data Transfers in Slave and DMA Modes for details.
    - USB DOEPx CTL.EPENA = 1
  - Depending on the type of Setup command received, the application can be required to program registers in the core to execute
    the received Setup command.
- 3. For the status IN phase, the application must program the core described in 15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode to perform a data IN transfer.
- 4. Assertion of the USB DIEPx INT.XFERCOMPL interrupt indicates the completion of the status IN phase of the control transfer.
- 5. The previous step must be repeated until the USB\_DIEPx\_INT.XFERCOMPL interrupt is detected on the endpoint, marking the completion of the two-stage control transfer.

### **Example: Two-Stage Control Transfer**

These notes refer to the following figure.

- 1. SETUP packet #1 is received on the USB and is written to the receive FIFO, and the core responds with an ACK handshake. This handshake is lost and the host detects a timeout.
- 2. The SETUP packet in the receive FIFO results in a USB\_GINTSTS.RXFLVL interrupt to the application, causing the application to empty the receive FIFO.
- 3. SETUP packet #2 on the USB is written to the receive FIFO, and the core responds with an ACK handshake.
- 4. The SETUP packet in the receive FIFO sends the application the USB\_GINTSTS.RXFLVL interrupt and the application empties the receive FIFO.
- 5. After the second SETUP packet, the host sends a control IN token for the status phase. The core issues a NAK response to this token, and writes a Setup Stage Done entry to the receive FIFO. This entry results in a USB\_GINTSTS.RXFLVL interrupt to the application, which empties the receive FIFO. After reading out the Setup Stage Done DWORD, the core asserts the USB\_DOEPx\_INT.SETUP packet interrupt to the application.
- 6. On this interrupt, the application processes SETUP Packet #2, decodes it to be a two-stage control command, and clears the control IN NAK bit.
  - USB\_DIEPx\_CTL.CNAK = 1
- 7. When the application clears the IN NAK bit, the core interrupts the application with a USB\_DIEPx\_INT.INTKNTXFEMP interrupt. On this interrupt, the application enables the control IN endpoint with a USB\_DIEPx\_TSIZ.XFERSIZE of 0 and a USB\_DIEPx\_TSIZ.PKTCNT of 1. This results in a zero-length data packet for the status IN token on the USB.
- 8. At the end of the status IN phase, the core interrupts the application with a USB\_DIEPx\_INT.XFERCOMPL interrupt.

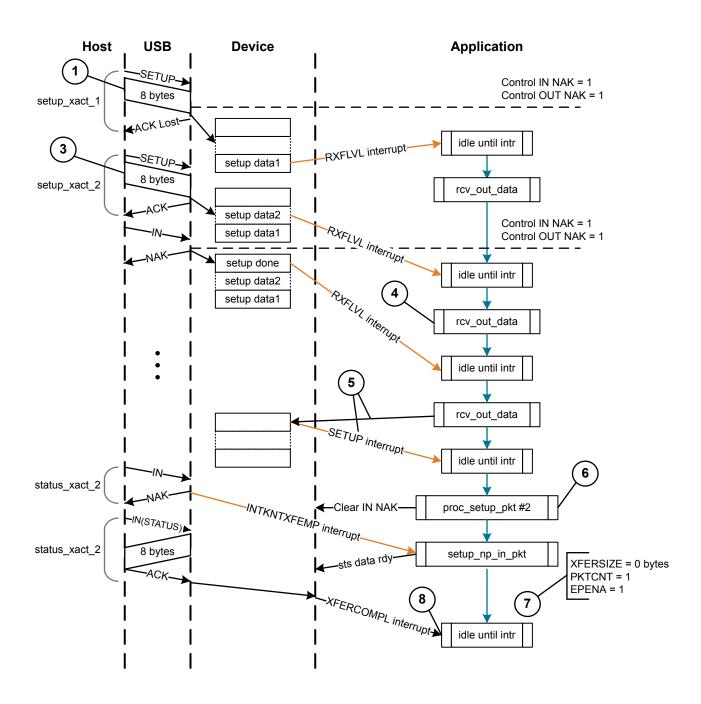

Figure 15.20. Two-Stage Control Transfer

## 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO in Slave mode.

- 1. On catching a USB GINTSTS.RXFLVL interrupt, the application must read the Receive Status Pop register (USB GRXSTSP).
- 2. The application can mask the USB\_GINTSTS.RXFLVL interrupt by writing to USB\_GINTMSK.RXFLVL = 0, until it has read the packet from the receive FIFO.
- 3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive Data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the Receive Data FIFO.
- 4. The receive FIFO's packet status readout indicates one of the following.
- 5. Global OUT NAK Pattern: PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = Dont Care (0x0), DPID = Dont Care (0b00). This data indicates that the global OUT NAK bit has taken effect.
  - a. SETUP Packet Pattern: PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num, DPID = D0. This data indicates that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
  - b. Setup Stage Done Pattern: PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EPNum, DPID = Don't Care (0b00). This data indicates that the Setup stage for the specified endpoint has completed and the Data stage has started. After this entry is popped from the receive FIFO, the core asserts a Setup interrupt on the specified control OUT endpoint.
  - c. Data OUT Packet Pattern: PKTSTS = DataOUT, BCNT = size of the Received data OUT packet, EPNUM = EPNum on which the packet was received, DPID = Actual Data PID.
  - d. Data Transfer Completed Pattern: PKTSTS = Data OUT Transfer Done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = Dont Care (0b00). This data indicates that a OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a Transfer Completed interrupt on the specified OUT endpoint.

The encoding for the PKTSTS is listed in the USB register descriptions.

- 6. After the data payload is popped from the receive FIFO, the USB GINTSTS.RXFLVL interrupt must be unmasked.
- 7. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to USB\_GINTSTS.RXFLVL. Reading an empty receive FIFO can result in undefined core behavior.

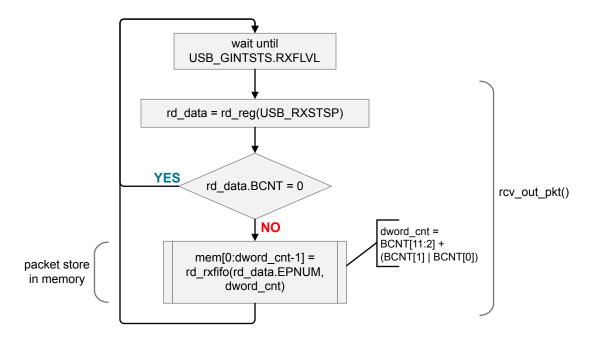

Figure 15.21. Receive FIFO Packet Read in Slave Mode

## 15.4.4.2.2.5 Setting the Global OUT NAK

#### **Internal Data Flow**

- 1. When the application sets the Global OUT NAK (USB\_DCTL.SGOUTNAK), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets
- 2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern. See 15.4.7.1 Data FIFO RAM Allocation.
- When either the core (in DMA mode) or the application (in Slave mode) pops the Global OUT NAK pattern DWORD from the receive FIFO, the core sets the USB\_GINTSTS.GOUTNAKEFF interrupt.
- 4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the USB\_DCTL.SGOUTNAK bit.

#### **Application Programming Sequence**

- 1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field.
  - USB DCTL.SGOUTNAK = 1
- 2. Wait for the assertion of the interrupt USB\_GINTSTS.GOUTNAKEFF. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
- 3. The application can receive valid OUT packets after it has set USB\_DCTL.SGOUTNAK and before the core asserts the USB GINTSTS.GOUTNAKEFF interrupt.
- 4. The application can temporarily mask this interrupt by writing to the USB GINTMSK.GOUTNAKEFFMSK bit.
  - USB GINTMSK.GINNAKEFFMSK = 0
- 5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the USB\_DCTL.SGOUTNAK bit. This also clears the USB\_GINTSTS.GOUTNAKEFF interrupt.
  - USB\_DCTL.CGOUTNAK = 1
- 6. If the application has masked this interrupt earlier, it must be unmasked as follows:
  - USB\_GINTMSK.GOUTNAKEFFMSK = 1

### 15.4.4.2.2.6 Disabling an OUT Endpoint

The application must use this sequence to disable an OUT endpoint that it has enabled.

### **Application Programming Sequence**

- 1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, as described in 15.4.4.2.2.5 Setting the Global OUT NAK.
  - USB\_DCTL.SGOUTNAK = 1
  - Wait for the USB GINTSTS.GOUTNAKEFF interrupt
- 2. Disable the required OUT endpoint by programming the following fields:
  - USB\_DOEPx\_CTL.EPDIS = 1
  - USB DOEPx CTL.SNAK = 1
- 3. Wait for the USB\_DOEPx\_INT.EPDISBLD interrupt, which indicates that the OUT endpoint is completely disabled. When the EP-DISBLD interrupt is asserted, the core also clears the following bits.
  - USB DOEPx CTL.EPDIS = 0
  - USB DOEPx CTL.EPENA = 0
- 4. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
  - USB\_DCTL.SGOUTNAK = 0

# 15.4.4.2.2.7 Stalling a Non-Isochronous OUT Endpoint

This section describes how the application can stall a non-isochronous endpoint.

- 1. Put the core in the Global OUT NAK mode, as described in 15.4.4.2.2.5 Setting the Global OUT NAK.
- 2. Disable the required endpoint, as described in Section 15.4.4.2.2.6 Disabling an OUT Endpoint.
  - When disabling the endpoint, instead of setting the USB\_DOEPx\_CTL.SNAK bit, set USB\_DOEPx\_CTL.STALL = 1.
    - The Stall bit always takes precedence over the NAK bit.
- 3. When the application is ready to end the STALL handshake for the endpoint, the USB DOEPx CTL.STALL bit must be cleared.
- 4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature. Endpoint Halt or ClearFeature. Endpoint Halt command, the Stall bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

### 15.4.4.2.2.8 Generic Non-Isochronous OUT Data Transfers in DMA and Slave Modes

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. See 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

#### **Application Requirements**

- 1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer, then program that buffer's size and start address (in DMA mode) in the endpoint-specific registers.
- 2. For OUT transfers, the Transfer Size field in the endpoint's Transfer Size register must be a multiple of the maximum packet size of the endpoint, adjusted to the DWORD boundary.

```
if (mps[epnum] mod 4) == 0
    transfer size[epnum] = n * (mps[epnum]) //Dword Aligned
else
    transfer size[epnum] = n * (mps[epnum] + 4 - (mps[epnum] mod 4)) //Non Dword Aligned

packet count[epnum] = n
n > 0
```

- 3. In DMA mode, the core stores a received data packet in the memory, always starting on a DWORD boundary. If the maximum packet size of the endpoint is not a multiple of 4, the core inserts byte pads at end of a maximum-packet-size packet up to the end of the DWORD.
- 4. On any OUT endpoint interrupt, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
  - Payload size in memory = application-programmed initial transfer size core updated final transfer size
  - Number of USB packets in which this payload was received = application-programmed initial packet count core updated final
    packet count

#### Internal Data Flow

- 1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
- 2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
  - OUT data packets received with Bad Data CRC are flushed from the receive FIFO automatically.
  - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which
    cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
  - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
  - In all the above three cases, the packet count is not decremented because no data is written to the receive FIFO.
- 3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
- 4. After the data is written to the receive FIFO, either the application (in Slave mode) or the core's DMA engine (in DMA mode), reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
- 5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
- 6. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
  - The transfer size is 0 and the packet count is 0
  - The last OUT data packet written to the receive FIFO is a short packet (0 <= packet size < maximum packet size)
- 7. When either the application or the DMA pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint and the endpoint enable is cleared.

## **Application Programming Sequence**

- 1. Program the USB\_DOEPx\_TSIZ register for the transfer size and the corresponding packet count. Additionally, in DMA mode, program the USB\_DOEPx\_DMAADDR register.
- 2. Program the USB\_DOEPx\_CTL register with the endpoint characteristics, and set the Endpoint Enable and ClearNAK bits.
  - USB DOEPx CTL.EPENA = 1
  - USB DOEPx CTL.CNAK = 1
- 3. In Slave mode, wait for the USB\_GINTSTS.RXFLVL level interrupt and empty the data packets from the receive FIFO as explained in 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.
  - This step can be repeated many times, depending on the transfer size.
- 4. Asserting the USB DOEPx INT.XFERCOMPL interrupt marks a successful completion of the non-isochronous OUT data transfer.
- 5. Read the USB DOEPx TSIZ register to determine the size of the received data payload.

Note: The XFERSIZE is not decremented for the last packet. This is as per design behavior.

### Slave Mode Bulk OUT Transaction

The following figure depicts the reception of a single bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

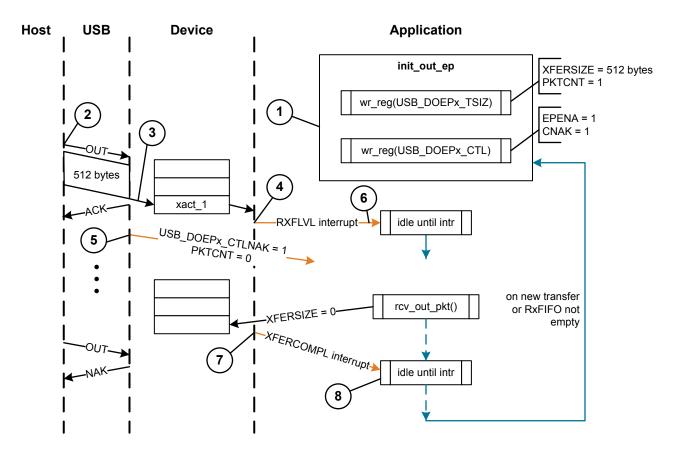

Figure 15.22. Slave Mode Bulk OUT Transaction

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting USB\_DOEPx\_CTL.CNAK = 1 and USB\_DOEPx\_CTL.EPENA = 1, and setting a suitable XFERSIZE and PKTCNT in the USB\_DOEPx\_TSIZ register.

- 1. Host attempts to send data (OUT token) to an endpoint.
- 2. When the core receives the OUT token on the USB, it stores the packet in the RxFIFO because space is available there.
- 3. After writing the complete packet in the RxFIFO, the core then asserts the USB\_GINTSTS.RXFLVL interrupt.
- 4. On receiving the PKTCNT number of USB packets, the core sets the NAK bit for this endpoint internally to prevent it from receiving any more packets.
- 5. The application processes the interrupt and reads the data from the RxFIFO.
- 6. When the application has read all the data (equivalent to XFERSIZE), the core generates a USB\_DOEPx\_INT.XFERCOMPL interrupt.
- 7. The application processes the interrupt and uses the setting of the USB\_DOEPx\_INT.XFERCOMPL interrupt bit to determine that the intended transfer is complete.

#### 15.4.4.2.2.9 Generic Isochronous OUT Data Transfer in DMA and Slave Modes

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. See 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.

This section describes a regular isochronous OUT data transfer.

### **Application Requirements**

- 1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers
- 2. For isochronous OUT data transfers, the Transfer Size and Packet Count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
  - 1 <= packet count[epnum] <= 3</li>
- 3. In Slave mode, when isochronous OUT endpoints are supported in the device, the application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (USB\_GINTSTS.EOPF interrupt). In DMA mode, the application must guarantee enough bandwidth to allow emptying the isochronous OUT data packet from the receive FIFO before the end of each periodic frame.
- 4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the USB\_GINTSTS.EOPF and before the USB\_GINTSTS.SOF.

#### **Internal Data Flow**

- 1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
- 2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on a isochronous OUT endpoint in a particular frame only if the following condition is met.
  - USB\_DOEPx\_CTL.DPIDEOF (Even/Odd frame) = USB\_DSTS.SOFFN[0]
- 3. When either the application or the internal DMA completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the USB\_DOEPx\_TSIZ.RXDPIDSUPCNT (Received DPID) field with the data PID of the last isochronous OUT data packet read from the receive FIFO.

### **Application Programming Sequence**

- 1. Program the USB\_DOEPx\_TSIZ register for the transfer size and the corresponding packet count. When in DMA mode, also program the USB\_DOEPx\_DMAADDR register.
- Program the USB\_DOEPx\_CTL register with the endpoint characteristics and set the Endpoint Enable, ClearNAK, and Even/Odd frame bits.
  - Endpoint Enable = 1
  - CNAK = 1
  - Even/Odd frame = (0: Even/1: Odd)
- 3. In Slave mode, wait for the USB\_GINTSTS.Rx StsQ level interrupt and empty the data packets from the receive FIFO as explained in 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.
  - This step can be repeated many times, depending on the transfer size.
- 4. The assertion of the USB\_DOEPx\_INT.XFERCOMPL interrupt marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
- 5. This interrupt can not always be detected for isochronous OUT transfers. Instead, the application can detect the USB\_GINTSTS.INCOMPLP (Incomplete Isochronous OUT data) interrupt. See 15.4.4.2.2.12 Incomplete Isochronous OUT Data Transfers in DMA and Slave Modes, for more details
- 6. Read the USB\_DOEPx\_TSIZ register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met.
  - USB DOEPx TSIZ.RXDPID = D0 and the number of USB packets in which this payload was received = 1
  - USB\_DOEPx\_TSIZ.RXDPID = D1 and the number of USB packets in which this payload was received = 2
  - USB\_DOEPx\_TSIZ.RXDPID = D2 and the number of USB packets in which this payload was received = 3
    - The number of USB packets in which this payload was received = App Programmed Initial Packet Count Core Updated Final Packet Count

The application can discard invalid data packets.

### 15.4.4.2.2.10 Generic Interrupt OUT Data Transfers Using Periodic Transfer Interrupt Feature

This section describes a regular INTR OUT data transfer with the Periodic Transfer Interrupt feature.

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. See 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.

### **Application Requirements**

- 1. Before setting up a periodic OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer, then program that buffer's size and start address in the endpoint-specific registers.
- 2. For Interrupt OUT transfers, the Transfer Size field in the endpoint's Transfer Size register must be a multiple of the maximum packet size of the endpoint, adjusted to the DWORD boundary. The Transfer Size programmed can span across multiple frames based on the periodicity after which the application want to receive the USB\_DOEPx\_INT.XFERCOMPL interrupt
  - transfer size[epnum] = n \* (mps[epnum] + 4 (mps[epnum] mod 4))
  - packet count[epnum] = n
  - n > 0 (Higher value of n reduces the periodicity of the USB\_DOEPx\_INT.XFERCOMPL interrupt)
  - 1 < packet count[epnum] < n (Higher value of n reduces the periodicity of the USB\_DOEPx\_INT.XFERCOMPL interrupt)</li>
- 3. In DMA mode, the core stores a received data packet in the memory, always starting on a DWORD boundary. If the maximum packet size of the endpoint is not a multiple of 4, the core inserts byte pads at end of a maximum-packet-size packet up to the end of the DWORD. The application will not be informed about the frame number on which a specific packet has been received.
- 4. On USB\_DOEPx\_INT.XFERCOMPL interrupt, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
  - Payload size in memory = application-programmed initial transfer size core updated final transfer size.
  - Number of USB packets in which this payload was received = application-programmed initial packet count core updated final
    packet count.
  - If for some reason, the host stops sending tokens, there are no interrupts to the application, and the application must timeout on its own.
- 5. The assertion of the USB\_DOEPx\_INT.XFERCOMPL interrupt marks the completion of the interrupt OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
- 6. Read the USB\_DOEPx\_TSIZ register to determine the size of the received transfer and to determine the validity of the data received in the frame.

#### **Internal Data Flow**

- 1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
  - · The application must enable the USB DCTL.IGNRFRMNUM
- 2. When an interrupt OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame will be ignored by the core.
- 3. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
  - · OUT data packets received with Bad Data CRC or any packet error are flushed from the receive FIFO automatically.
  - Interrupt packets with PID errors are not passed to application. Core discards the packet, sends ACK and does not decrement
    packet count.
  - If there is no space in the receive FIFO, interrupt data packets are ignored and not written to the receive FIFO. Additionally, interrupt OUT tokens receive a NAK handshake reply.
- 4. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or interrupt data packets are ignored and not written to the receive FIFO, and interrupt OUT tokens receive a NAK handshake reply.
- 5. After the data is written to the receive FIFO, the core's DMA engine reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
- 6. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
- 7. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
  - The transfer size is 0 and the packet count is 0.
  - The last OUT data packet written to the receive FIFO is a short packet (0 < packet size < maximum packet size)
- 8. When either the application or the DMA pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint and the endpoint enable is cleared.

#### 15.4.4.2.2.11 Generic Isochronous OUT Data Transfers Using Periodic Transfer Interrupt Feature

This section describes a regular isochronous OUT data transfer with the Periodic Transfer Interrupt feature.

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. For packet writes in Slave mode, see 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.

### **Application Requirements**

- Before setting up ISOC OUT transfers spanned across multiple frames, the application must allocate buffer in the memory to accommodate all data to be received as part of the OUT transfers, then program that buffer's size and start address in the endpointspecific registers.
  - The application must mask the USB\_GINTSTS.INCOMPLP (Incomplete ISO OUT).
  - The application must enable the USB\_DCTL.IGNRFRMNUM
- 2. For ISOC transfers, the Transfer Size field in the USB\_DOEPx\_TSIZ.XFERSIZE register must be a multiple of the maximum packet size of the endpoint, adjusted to the DWORD boundary. The Transfer Size programmed can span across multiple frames based on the periodicity after which the application wants to receive the USB\_DOEPx\_INT.XFERCOMPL interrupt
  - transfer size[epnum] = n \* (mps[epnum] + 4 (mps[epnum] mod 4))
  - packet count[epnum] = n
  - n > 0 (Higher value of n reduces the periodicity of the USB\_DOEPx\_INT.XFERCOMPL interrupt)
  - 1 =< packet count[epnum] =< n (Higher value of n reduces the periodicity of the USB\_DOEPx\_INT.XFERCOMPL interrupt).
- 3. In DMA mode, the core stores a received data packet in the memory, always starting on a DWORD boundary. If the maximum packet size of the endpoint is not a multiple of 4, the core inserts byte pads at end of a maximum-packet-size packet up to the end of the DWORD. The application will not be informed about the frame number and the PID value on which a specific OUT packet has been received.
- 4. The assertion of the USB\_DOEPx\_INT.XFERCOMPL interrupt marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
  - On USB\_DOEPx\_INT.XFERCOMPL, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory.
  - Payload size in memory = application-programmed initial transfer size core updated final transfer size
  - Number of USB packets in which this payload was received = application-programmed initial packet count core updated final
    packet count.
  - If for some reason, the host stop sending tokens, there will be no interrupt to the application, and the application must timeout on its own.
- 5. The assertion of the USB\_DOEPx\_INT.XFERCOMPL can also mark a packet drop on USB due to unavailability of space in the RxFifo or due to any packet errors.
  - The application must read the USB\_DOEPx\_INT.PKTDRPSTS (USB\_DOEPx\_INT.Bit[11] is now used as the
    USB\_DOEPx\_INT.PKTDRPSTS) register to differentiate whether the USB\_DOEPx\_INT.XFERCOMPL was generated due to
    the normal end of transfer or due to dropped packets. In case of packets being dropped on the USB due to unavailability of
    space in the RxFifo or due to any packet errors the endpoint enable bit is cleared.
  - In case of packet drop on the USB application must re-enable the endpoint after recalculating the values USB\_DOEPx\_TSIZ.XFERSIZE and USB\_DOEPx\_TSIZ.PKTCNT.
  - Payload size in memory = application-programmed initial transfer size core updated final transfer size
  - Number of USB packets in which this payload was received = application-programmed initial packet count core updated final
    packet count.

**Note:** Due to application latencies it is possible that DOEPINT.XFERCOMPL interrupt is generated without DOEPINT.PKTDRPSTS being set, This scenario is possible only if back-to-back packets are dropped for consecutive frames and the PKTDRPSTS is merged, but the XFERSIZE and PktCnt values for the endpoint are nonzero. In this case, the application must proceed further by programming the PKTCNT and XFERSIZE register for the next frame, as it would if PKTDRPSTS were being set.

The following figure gives the application flow for Isochronous OUT Periodic Transfer Interrupt feature.

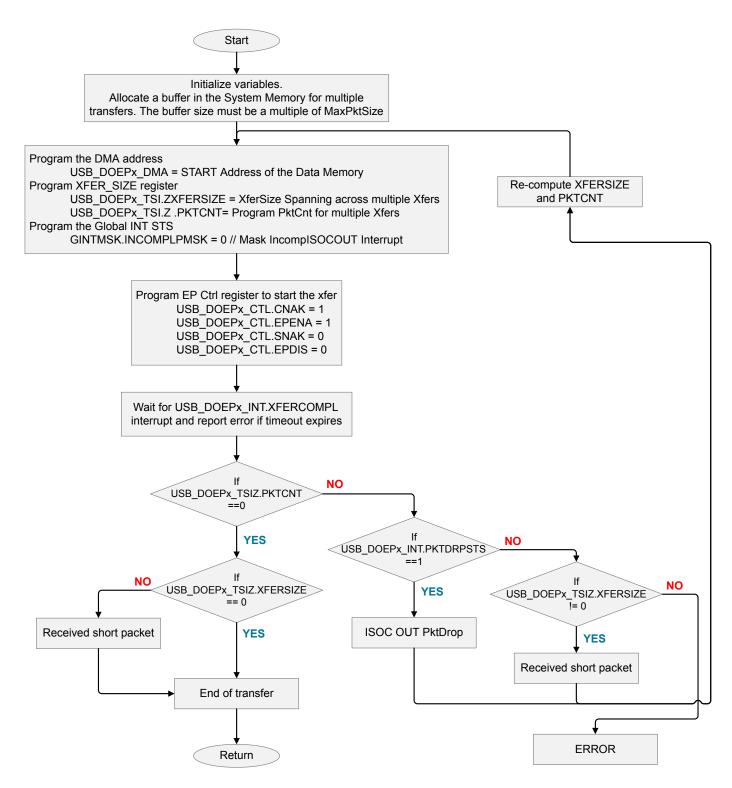

Figure 15.23. ISOC OUT Application Flow for Periodic Transfer Interrupt Feature

# 15.4.4.2.2.12 Incomplete Isochronous OUT Data Transfers in DMA and Slave Modes

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. See 15.4.4.2.2.4 Packet Read from FIFO in Slave Mode.

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

#### **Internal Data Flow**

- 1. For isochronous OUT endpoints, the USB\_DOEPx\_INT.XFERCOMPL interrupt possibly is not always asserted. If the core drops isochronous OUT data packets, the application could fail to detect the USB\_DOEPx\_INT.XFERCOMPL interrupt under the following circumstances.
  - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data.
  - When the isochronous OUT data packet is received with CRC errors.
  - · When the isochronous OUT token received by the core is corrupted.
  - When the application is very slow in reading the data from the receive FIFO.
- 2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the USB\_GINTSTS.INCOMPLP (Incomplete Isochronous OUT data) interrupt, indicating that a USB\_DOEPx\_INT.XFERCOMPL interrupt is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remains in progress on this endpoint on the USB.
- 3. This step is applicable only if the core is operating in slave mode. Application Programming Sequence
- 4. This step is applicable only if the core is operating in slave mode. Asserting the USB\_GINTSTS.INCOMPLP (Incomplete Isochronous OUT data) interrupt indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
- 5. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the DMA or the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
  - When all data is emptied from the receive FIFO, the application can detect the USB\_DOEPx\_INT.XFERCOMPL interrupt. In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame, as described in 15.4.4.2.2.2 Control Read Transfers (SETUP, Data IN, Status OUT).
- 6. When it receives a USB\_GINTSTS.incomplete Isochronous OUT data interrupt, the application must read the control registers of all isochronous OUT endpoints (USB\_DOEPx\_CTL) to determine which endpoints had an incomplete transfer in the current frame. An endpoint transfer is incomplete if both the following conditions are met.
  - USB DOEPx CTL.DPIDEOF (Even/Odd frame) = USB DSTS.SOFFN[0]
  - USB\_DOEPx\_CTL.EPENA (Endpoint Enable) = 1
- The previous step must be performed before the USB\_GINTSTS.SOF interrupt is detected, to ensure that the current frame number is not changed.
- 8. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the USB\_DOEPx\_CTL.EPDIS (Endpoint Disable) bit.
- 9. Wait for the USB\_DOEPx\_INT.EPDIS (Endpoint Disabled) interrupt and enable the endpoint to receive new data in the next frame as explained in 15.4.4.2.2.2 Control Read Transfers (SETUP, Data IN, Status OUT).
  - Because the core can take some time to disable the endpoint, the application possibly is not able to receive the data in the next frame after receiving bad isochronous data.

#### 15.4.4.2.3 IN Data Transfers in Slave and DMA Modes

This section describes the internal data flow and application-level operations during IN data transfers.

- 15.4.4.2.3.14 Generic Periodic IN Data Transfers Using the Periodic Transfer Interrupt Feature

#### 15.4.4.2.3.1 Packet Write in Slave Mode

This section describes how the application writes data packets to the endpoint FIFO in Slave mode.

- 1. The application can either choose polling or interrupt mode.
  - In polling mode, application monitors the status of the endpoint transmit data FIFO, by reading the USB\_DIEPx\_TXFSTS register, to determine, if there is enough space in the data FIFO.
  - In interrupt mode, application waits for the USB\_DIEPx\_INT.TXFEMP interrupt and then reads the USB\_DIEPx\_TXFSTS register, to determine, if there is enough space in the data FIFO.
  - · To write a single non-zero length data packet, there must be space to write the entire packet is the data FIFO.
  - For writing zero length packet, application must not look for FIFO space.
- 2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. The application, typically must do a read modify write on the USB\_DIEPx\_CTL, to avoid modifying the contents of the register, except for setting the Endpoint Enable bit.

The application can write multiple packets for the same endpoint, into the transmit FIFO, if space is available. For periodic IN endpoints, application must write packets only for one frame. It can write packets for the next periodic transaction, only after getting transfer complete for the previous transaction.

### 15.4.4.2.3.2 Setting Global Non-Periodic IN Endpoint NAK

### Internal Data Flow

- 1. When the application sets the Global Non-periodic IN NAK bit (USB\_DCTL.SGNPINNAK), the core stops transmitting data on the non-periodic endpoint, irrespective of data availability in the Non-periodic Transmit FIFO.
- 2. Non-isochronous IN tokens receive a NAK handshake reply
- 3. The core asserts the USB GINTSTS.GINNAKEFF interrupt in response to the USB DCTL.SGNPINNAK bit.
- 4. Once the application detects this interrupt, it can assume that the core is in the Global Non-periodic IN NAK mode. The application can clear this interrupt by clearing the USB DCTL.SGNPINNAK bit.

### Application Programming Sequence

- 1. To stop transmitting any data on non-periodic IN endpoints, the application must set the USB\_DCTL.SGNPINNAK bit. To set this bit, the following field must be programmed
  - USB DCTL.SGNPINNAK = 1
- Wait for the assertion of the USB\_GINTSTS.GINNAKEFF interrupt. This interrupt indicates the core has stopped transmitting data on the non-periodic endpoints.
- 3. The core can transmit valid non-periodic IN data after the application has set the USB\_DCTL.SGNPINNAK bit, but before the assertion of the USB\_GINTSTS.GINNAKEFF interrupt.
- 4. The application can optionally mask this interrupt temporarily by writing to the USB GINTMSK.GINNAKEFFMSK bit.
  - USB GINTMSK.GINNAKEFFMSK = 0
- 5. To exit Global Non-periodic IN NAK mode, the application must clear the USB\_DCTL.SGNPINNAK. This also clears the USB\_GINTSTS.GINNAKEFF interrupt.
  - USB DCTL.SGNPINNAK = 1
- 6. If the application has masked this interrupt earlier, it must be unmasked as follows:
  - USB\_GINTMSK.GINNAKEFFMSK = 1

### 15.4.4.2.3.3 Setting IN Endpoint NAK

#### **Internal Data Flow**

- 1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint's transmit FIFO.
- 2. Non-isochronous IN tokens receive a NAK handshake reply
  - · Isochronous IN tokens receive a zero-data-length packet reply
- 3. The core asserts the USB\_DIEPx\_INT.INEPNAKEFF (IN NAK Effective) interrupt in response to the USB\_DIEPx\_CTL.SNAK (Set NAK) bit.
- 4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the USB\_DIEPx\_CTL. Clear NAK bit.

### **Application Programming Sequence**

- To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
  - USB DIEPx CTL.SNAK = 1
- 2. Wait for assertion of the USB\_DIEPx\_INT.INEPNAKEFF (NAK Effective) interrupt. This interrupt indicates the core has stopped transmitting data on the endpoint.
- 3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
- 4. The application can mask this interrupt temporarily by writing to the USB\_DIEPMSK.INEPNAKEFFMSK (NAK Effective) bit.
  - USB DIEPMSK.INEPNAKEFFMSK (NAK Effective) = 0
- 5. To exit Endpoint NAK mode, the application must clear the USB\_DIEPx\_CTL.NAK status. This also clears the USB\_DIEPx\_INT.INEPNAKEFF (NAK Effective) interrupt.
  - USB\_DIEPx\_CTL.CNAK = 1
- 6. If the application masked this interrupt earlier, it must be unmasked as follows:
  - USB\_DIEPMSK.INEPNAKEFFMSK (NAK Effective) = 1

## 15.4.4.2.3.4 IN Endpoint Disable

Use the following sequence to disable a specific IN endpoint (periodic/non-periodic) that has been previously enabled.

### **Application Programming Sequence:**

- 1. In Slave mode, the application must stop writing data on the AHB, for the IN endpoint to be disabled.
- 2. The application must set the endpoint in NAK mode. See 15.4.4.2.3.3 Setting IN Endpoint NAK.
  - USB\_DIEPx\_CTL.SNAK = 1
- 3. Wait for USB DIEPx INT.INEPNAKEFF (NAK Effective) interrupt.
- 4. Set the following bits in the USB DIEPx CTL register for the endpoint that must be disabled.
  - USB DIEPx CTL.EPDIS (Endpoint Disable) = 1
  - USB DIEPx CTL.SNAK = 1
- 5. Assertion of USB\_DIEPx\_INT.EPDISBLD (Endpoint Disabled) interrupt indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits.
  - USB DIEPx CTL.EPENA = 0
  - USB\_DIEPx\_CTL.EPDIS = 0
- 6. The application must read the USB\_DIEPx\_TSIZ register for the periodic IN EP, to calculate how much data on the endpoint was transmitted on the USB.
- 7. The application must flush the data in the Endpoint transmit FIFO, by setting the following fields in the USB\_GRSTCTL register.
  - USB\_GRSTCTL.TXFNUM = Endpoint Transmit FIFO Number
  - USB\_GRSTCTL.TXFFLSH = 1

The application must poll the USB\_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

### 15.4.4.2.3.5 Bulk IN Stall

- 1. The application has scheduled an IN transfer on receiving the USB\_DIEPx\_INT.INTKNTXFEMP (IN Token Received When TxFI-FO Empty) interrupt.
- 2. When the transfer is in progress, the application must force a STALL on the endpoint. This could be because the application has received a SetFeature. Endpoint Halt command. The application sets the Stall bit, disables the endpoint and waits for the USB DIEPx INT. EPDISBLD (Endpoint Disabled) interrupt. This generates STALL handshakes for the endpoint on the USB.
- 3. On receiving the interrupt, the application flushes the Non-periodic Transmit FIFO and clears the USB\_DCTL.SGNPINNAK (Global IN NP NAK) bit.
- 4. On receiving the ClearFeature. Endpoint Halt command, the application clears the Stall bit.
- 5. The endpoint behaves normally and the application can re-enable the endpoint for new transfers

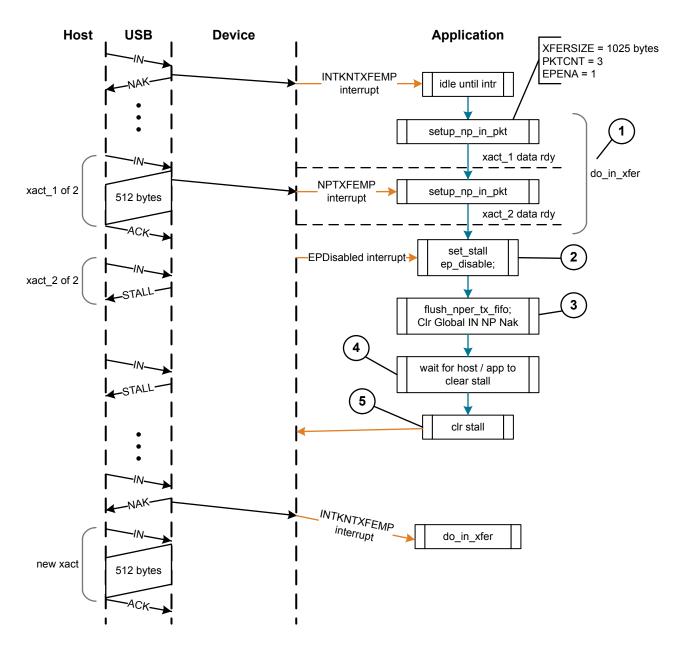

Figure 15.24. Bulk IN Stall

### 15.4.4.2.3.6 Incomplete Isochronous IN Data Transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

#### **Internal Data Flow**

- 1. An isochronous IN transfer is treated as incomplete in one of the following conditions.
  - a. The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects a USB\_GINTSTS.INCOMPISOIN (Incomplete Isochronous IN Transfer) interrupt.
  - b. The application or DMA is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects a USB\_DIEPx\_INT.INTKNTXFEMP (IN Token Received When TxFIFO Empty) interrupt. The application can ignore this interrupt, as it eventually results in a USB GINTSTS.INCOMPISOIN (Incomplete Isochronous IN Transfer) interrupt at the end of periodic frame.
    - i. The core transmits a zero-length data packet on the USB in response to the received IN token.
- 2. In either of the aforementioned cases, in Slave mode, the application must stop writing the data payload to the transmit FIFO as soon as possible.
- 3. The application must set the NAK bit and the disable bit for the endpoint. In DMA mode, the core automatically stops fetching the data payload when the endpoint disable bit is set.
- 4. The core disables the endpoint, clears the disable bit, and asserts the Endpoint Disable interrupt for the endpoint.

## **Application Programming Sequence**

- 1. The application can ignore the USB\_DIEPx\_INT.INTKNTXFEMP (IN Token Received When TxFIFO empty) interrupt on any iso-chronous IN endpoint, as it eventually results in a USB\_GINTSTS.INCOMPISOIN (Incomplete Isochronous IN Transfer) interrupt.
- Assertion of the USB\_GINTSTS.INCOMPISOIN (Incomplete Isochronous IN Transfer) interrupt indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
- 3. The application must read the Endpoint Control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
- 4. In Slave mode, the application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
- 5. In both modes of operation, program the following fields in the USB\_DIEPx\_CTL register to disable the endpoint.
  - USB\_DIEPx\_CTL.SNAK = 1
  - USB DIEPx CTL.EPDIS (Endpoint Disable) = 1
- 6. The USB\_DIEPx\_INT.EPDISBLD (Endpoint Disabled) interrupt's assertion indicates that the core has disabled the endpoint.
  - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by
    enabling the endpoint for a new transfer in the next frame. To flush the data, the application must use the USB\_GRSTCTL register.

## 15.4.4.2.3.7 Stalling Non-Isochronous IN Endpoints

This section describes how the application can stall a non-isochronous endpoint.

## **Application Programming Sequence**

- 1. Disable the IN endpoint to be stalled. Set the Stall bit as well.
- USB DIEPx CTL.EPDIS (Endpoint Disable) = 1, when the endpoint is already enabled.
  - USB DIEPx CTL.STALL = 1
  - · The Stall bit always takes precedence over the NAK bit
- 3. Assertion of the USB\_DIEPx\_INT.EPDISBLD (Endpoint Disabled) interrupt indicates to the application that the core has disabled the specified endpoint.
- 4. The application must flush the Non-periodic or Periodic Transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints, which do not need to be stalled, to transmit data.
- 5. Whenever the application is ready to end the STALL handshake for the endpoint, the USB\_DIEPx\_CTL.STALL bit must be cleared.
- 6. If the application sets or clears a STALL for an endpoint due to a SetFeature. Endpoint Halt command or ClearFeature. Endpoint Halt command, the Stall bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

### Special Case: Stalling the Control IN/OUT Endpoint

The core must stall IN/OUT tokens if, during the Data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must to enable USB\_DIEPx\_INT.INTKNTXFEMP and USB\_DOEPx\_INT.OUTTKNEPDIS interrupts during the Data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

## 15.4.4.2.3.8 Worst-Case Response Time

When the acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token could come sooner. This worst case value is 7 PHY clocks in FS mode.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the INCOMPISOIN and INCOMPLP interrupts inform the application that isochronous IN/OUT packets were dropped.

# 15.4.4.2.3.9 Choosing the Value of USB\_GUSBCFG.USBTRDTIM

The value in USB\_GUSBCFG.USBTRDTIM is the time it takes for the MAC, in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data from PFC (Packet FIFO Controller) block. This time involves the synchronization delay between the PHY and AHB clocks. This delay is 5 clocks.

Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes it into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY (in Low-speed mode), the application can use a smaller value for USB\_GUSBCFG.USBTRDTIM. The following figure explains the 5-clock delay. This diagram has the following signals:

- tkn\_rcvd: Token received information from MAC to PFC
- · dynced tkn rcvd: Doubled sync tkn rcvd, from pclk to hclk domain
- · spr read: Read to SPRAM
- · spr addr: Address to SPRAM
- · spr rdata: Read data from SPRAM
- · srcbuf push: Push to the source buffer
- · srcbuf rdata: Read data from the source buffer. Data seen by MAC

The application can use the following formula to calculate the value of USB GUSBCFG.USBTRDTIM:

.... approach can use the remaining community and raise of the first community and the remaining community and the

# 15.4.4.2.3.10 Handling Babble Conditions

If receives a packet that is larger than the maximum packet size for that endpoint, the core stops writing data to the Rx buffer and waits for the end of packet (EOP). When the core detects the EOP, it flushes the packet in the Rx buffer and does not send any response to the host.

4 × AHB Clock + 1 PHY Clock = (2 clock sync + 1 clock memory address + 1 clock memory data from sync RAM) + (1 PHY Clock (next PHY clock

If the core continues to receive data at the EOF2 (the end of frame 2, which is very close to SOF), the core generates an early\_suspend interrupt (USB\_GINTSTS.ERLYSUSP). On receiving this interrupt, the application must check the erratic\_error status bit (USB\_DSTS.ERRTICERR). If this bit is set, the application must take it as a long babble and perform a soft reset.

### 15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. For packet writes in Slave mode, see 15.4.4.2.3.1 Packet Write in Slave Mode.

### **Application Requirements**

- 1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer is part of a single buffer, and must program the size of that buffer and its start address (in DMA mode) to the endpoint-specific registers.
- 2. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
  - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
  - Transfer size[epnum] = n \* mps[epnum] + sp (where n is an integer >= 0, and 0 <= sp < mps[epnum])
  - If (sp > 0), then packet count[epnum] = n + 1. Otherwise, packet count[epnum] = n
  - a. To transmit a single zero-length data packet:
    - Transfer size[epnum] = 0
    - Packet count[epnum] = 1
  - b. To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer in two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
  - c. First transfer: transfer size[epnum] = n \* mps[epnum]; packet count = n;
  - d. Second transfer: transfer size[epnum] = 0; packet count = 1;
- 3. In DMA mode, the core fetches an IN data packet from the memory, always starting at a DWORD boundary. If the maximum packet size of the IN endpoint is not a multiple of 4, the application must arrange the data in the memory with pads inserted at the end of a maximum-packet-size packet so that a new packet always starts on a DWORD boundary.
- 4. Once an endpoint is enabled for data transfers, the core updates the Transfer Size register. At the end of IN transfer, which ended with a Endpoint Disabled interrupt, the application must read the Transfer Size register to determine how much data posted in the transmit FIFO was already sent on the USB.
- 5. Data fetched into transmit FIFO = Application-programmed initial transfer size core-updated final transfer size
  - Data transmitted on USB = (application-programmed initial packet count Core updated final packet count) \* mps[epnum]
  - Data yet to be transmitted on USB = (Application-programmed initial transfer size data transmitted on USB)

#### **Internal Data Flow**

- 1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
- 2. In Slave mode, the application must also write the required data to the transmit FIFO for the endpoint. In DMA mode, the core fetches the data from memory according to the application setting for the endpoint.
- 3. Every time a packet is written into the transmit FIFO, either by the core's internal DMA (in DMA mode) or the application (in Slave Mode), the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory (DMA/Application), until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the "number of packets in FIFO" count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
- 4. Once the data is written to the transmit FIFO, the core reads it out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a TIMEOUT.
- 5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the Packet Count field.
- 6. If there is no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates a IN Tkn Rcvd When FIFO Empty Interrupt for the endpoint, provided the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
- 7. For Control IN endpoint, if there is a TIMEOUT condition, the USB\_DIEPx\_INT.TIMEOUT interrupt is generated.
- 8. When the transfer size is 0 and the packet count is 0, the transfer complete interrupt for the endpoint is generated and the endpoint enable is cleared.

### **Application Programming Sequence**

- 1. Program the USB\_DIEPx\_TSIZ register with the transfer size and corresponding packet count. In DMA mode, also program the USB DIEPx DMAADDR register.
- 2. Program the USB DIEPx CTL register with the endpoint characteristics and set the CNAK and Endpoint Enable bits.
- 3. In slave mode when transmitting non-zero length data packet, the application must poll the USB\_DIEPx\_TXFSTS register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use USB\_DIEPx\_INT.TXFEMP before writing the data.

### 15.4.4.2.3.12 Examples

#### Slave Mode Bulk IN Transaction

- 1. The host attempts to read data (IN token) from an endpoint.
- 2. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO.
- 3. To indicate to the application that there was no data to send, the core generates a USB\_DIEPx\_INT.INTKNTXFEMP (IN Token Received When TxFIFO Empty) interrupt.
- 4. When data is ready, the application sets up the USB\_DIEPx\_TSIZ register with the Transfer Size and Packet Count fields.
- 5. The application writes one maximum packet size or less of data to the Non-periodic TxFIFO.
- 6. The host reattempts the IN token.
- 7. Because data is now ready in the FIFO, the core now responds with the data and the host ACKs it.
- 8. Because the XFERSIZE is now zero, the intended transfer is complete. The device core generates a USB\_DIEPx\_INT.XFER-COMPL interrupt.
- 9. The application processes the interrupt and uses the setting of the USB\_DIEPx\_INT.XFERCOMPL interrupt bit to determine that the intended transfer is complete.

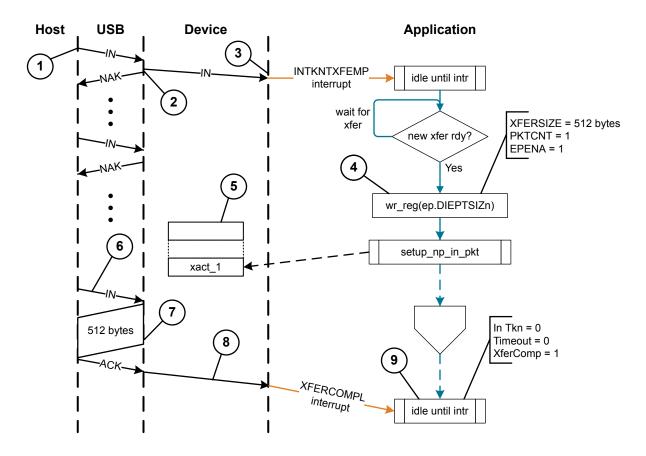

Figure 15.25. Slave Mode Bulk IN Transaction

### Slave Mode Bulk IN Transfer (Pipelined Transaction)

- 1. The host attempts to read data (IN token) from an endpoint.
- 2. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO.
- 3. To indicate that there was no data to send, the core generates an USB\_DIEPx\_INT.INTKNTXFEMP (In Token Received When TxFIFO Empty) interrupt.
- 4. When data is ready, the application sets up the USB\_DIEPx\_TSIZ register with the transfer size and packet count.
- 5. The application writes one maximum packet size or less of data to the Non-periodic TxFIFO.
- 6. The host reattempts the IN token.
- 7. Because data is now ready in the FIFO, the core responds with the data, and the host ACKs it.
- 8. When the TxFIFO level falls below the halfway mark, the core generates a USB\_GINTSTS.NPTXFEMP (NonPeriodic TxFIFO Empty) interrupt. This triggers the application to start writing additional data packets to the FIFO.
- 9. A data packet for the second transaction is ready in the TxFIFO.
- 10. A data packet for third transaction is ready in the TxFIFO while the data for the second packet is being sent on the bus.
- 11. The second data packet is sent to the host.
- 12. The last short packet is sent to the host.
- 13. Because the last packet is sent and XFERSIZE is now zero, the intended transfer is complete. The core generates a USB\_DIEPx\_INT.XFERCOMPL interrupt.
- 14. The application processes the interrupt and uses the setting of the USB\_DIEPx\_INT.XFERCOMPL interrupt bit to determine that the intended transfer is complete

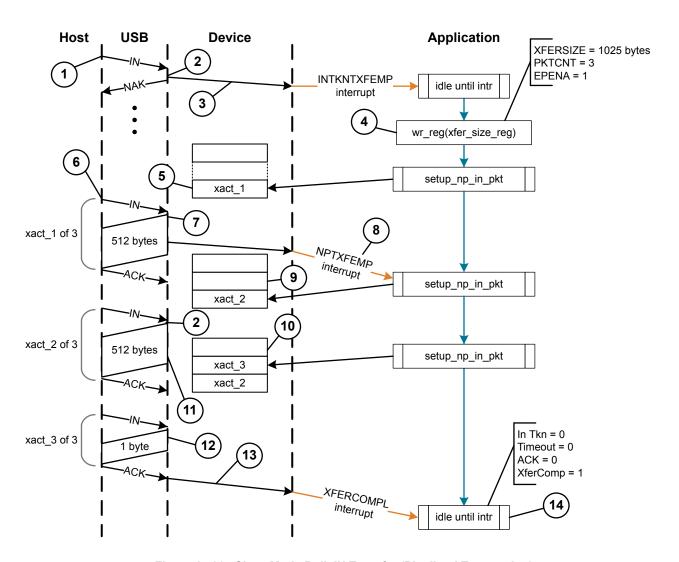

Figure 15.26. Slave Mode Bulk IN Transfer (Pipelined Transaction)

## Slave Mode Bulk IN Two-Endpoint Transfer

- 1. The host attempts to read data (IN token) from endpoint 1.
- 2. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO for endpoint 1, and generates a USB\_DIEP1\_INT.INTKNTXFEMP (In Token Received When TxFIFO Empty) interrupt.
- 3. The application processes the interrupt and initializes USB\_DIEP1\_TSIZ register with the Transfer Size and Packet Count fields. The application starts writing the transaction data to the transmit FIFO.
- 4. The application writes one maximum packet size or less of data for endpoint 1 to the Non-periodic TxFIFO.
- 5. Meanwhile, the host attempts to read data (IN token) from endpoint 2.
- 6. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO for endpoint 2, and the core generates a USB\_DIEP2\_INT.INTKNTXFEMP (In Token Received When TxFIFO Empty) interrupt.
- 7. Because the application has completed writing the packet for endpoint 1, it initializes the USB\_DIEP2\_TSIZ register with the Transfer Size and Packet Count fields. The application starts writing the transaction data into the transmit FIFO for endpoint 2.
- 8. The host repeats its attempt to read data (IN token) from endpoint 1.
- 9. Because data is now ready in the TxFIFO, the core returns the data, which the host ACKs.
- 10. Meanwhile, the application has initialized the data for the next two packets in the TxFIFO (ep2.xact1 and ep1.xact2, in order).
- 11. The host repeats its attempt to read data (IN token) from endpoint 2.
- 12. Because endpoint 2's data is ready, the core responds with the data (ep2.xact 1), which the host ACKs.
- 13. Meanwhile, the application has initialized the data for the next two packets in the TxFIFO (ep2.xact2 and ep1.xact3, in order). The application has finished initializing data for the two endpoints involved in this scenario.
- 14. The host repeats its attempt to read data (IN token) from endpoint 1.
- 15. Because data is now ready in the FIFO, the core responds with the data, which the host ACKs.
- 16. The host repeats its attempt to read data (IN token) from endpoint 2.
- 17. With data now ready in the FIFO, the core responds with the data, which the host ACKs.
- 18. With the last packet for endpoint 2 sent and its XFERSIZE now zero, the intended transfer is complete. The core generates a USB\_DIEP2\_INT.XFERCOMPL interrupt for this endpoint.
- 19. The application processes the interrupt and uses the setting of the USB\_DIEP2\_INT.XFERCOMPL interrupt bit to determine that the intended transfer on endpoint 2 is complete.
- 20. The host repeats its attempt to read data (IN token) from endpoint 1 (last transaction).
- 21. With data now ready in the FIFO, the core responds with the data, which the host ACKs.
- 22. Because the last endpoint one packet has been sent and XFERSIZE is now zero, the intended transfer is complete. The core generates a USB\_DIEP1\_INT.XFERCOMPL interrupt for this endpoint.
- 23. The application processes the interrupt and uses the setting of the USB\_DIEP1\_INT.XFERCOMPL interrupt bit to determine that the intended transfer on endpoint 1 is complete.

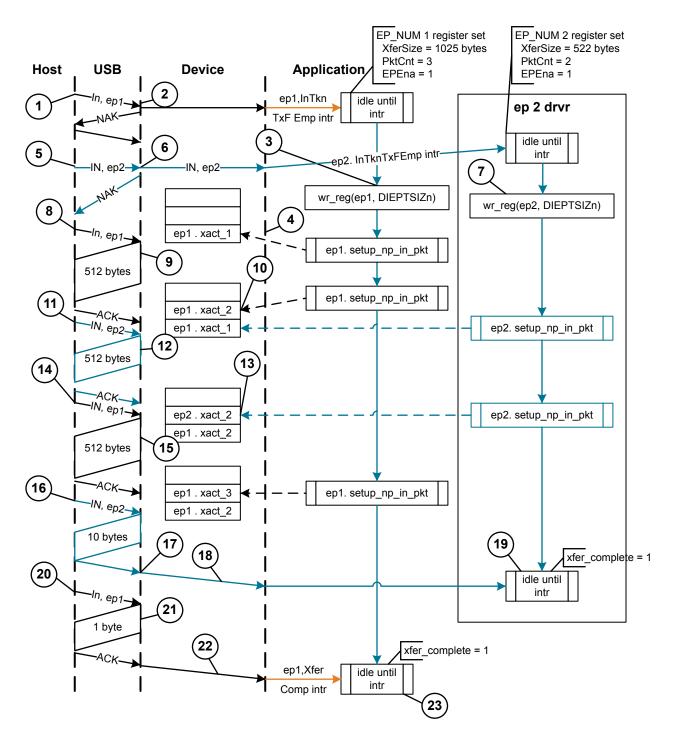

Figure 15.27. Slave Mode Bulk IN Two-Endpoint Transfer

# 15.4.4.2.3.13 Generic Periodic IN (Interrupt and Isochronous) Data Transfers

To initialize the core after power-on reset, the application must follow the sequence in 15.4.1 Overview: Programming the Core. Before it can communicate with the host, it must initialize an endpoint as described in 15.4.4.1 Endpoint Initialization. For packet writes in Slave mode, see 15.4.4.2.3.1 Packet Write in Slave Mode.

## **Application Requirements**

- 1. Application requirements 1, 2, 3, and 4 of 15.4.4.2.3.11 Generic Non-Periodic (Bulk and Control) IN Data Transfers in DMA and Slave Mode also apply to periodic IN data transfers, except for a slight modification of Requirement 2.
  - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met.
    - transfer size[epnum] = n \* mps[epnum] + sp(where n is an integer # 0, and 0 >= sp < mps[epnum])
    - If (sp > 0), packet count[epnum] = n + 1Otherwise, packet count[epnum] = n;
    - mc[epnum] = packet count[epnum]
  - The application cannot transmit a zero-length data packet at the end of transfer. It can transmit a single zero-length data packet by it self. To transmit a single zero-length data packet,
  - transfer size[epnum] = 0
    - packet count[epnum] = 1
    - mc[epnum] = packet count[epnum]
- 2. The application can only schedule data transfers 1 frame at a time.
  - (USB\_DIEPx\_TSIZ.MC 1) \* USB\_DIEPx\_CTL.MPS =< USB\_DIEPx\_TSIZ.XFERSIZE =< USB\_DIEPx\_TSIZ.MC \*
     USB\_DIEPx\_CTL.MPS</li>
  - USB DIEPx TSIZ.PKTCNT = USB DIEPx TSIZ.MC
  - If USB\_DIEPx\_TSIZ.XFERSIZE < USB\_DIEPx\_TSIZ.MC \* USB\_DIEPx\_CTL.MPS, the last data packet of the transfer is a short packet.
- 3. This step is not applicable for isochronous data transfers, only for interrupt transfers. The application can schedule data transfers for multiple frames, only if multiples of max packet sizes (up to 3 packets), must be transmitted every frame. This is can be done, only when the core is operating in DMA mode. This is not a recommended mode though.
  - ((n\*USB\_DIEPx\_TSIZ.MC) 1)\*USB\_DIEPx\_CTL.MPS <= USB\_DIEPx\_TSIZ.XFERSIZE <= n\*USB\_DIEPx\_TSIZ.MC\*USB\_DIEPx\_CTL.MPS
  - USB\_DIEPx\_TSIZ.PKTCNT = n\*USB\_DIEPx\_TSIZ.MC
  - · n is the number of frames for which the data transfers are scheduled

Data Transmitted per frame in this case would be USB\_DIEPx\_TSIZ.MC\*USB\_DIEPx\_CTL.MPS, in all the frames except the last one. In the frame "n", the data transmitted would be (USB\_DIEPx\_TSIZ.XFERSIZE - (n-1)\*USB\_DIEPx\_TSIZ.MC\*USB\_DIEPx\_CTL.MPS)

- 4. For Periodic IN endpoints, the data must always be prefetched 1 frame ahead for transmission in the next frame. This can be done, by enabling the Periodic IN endpoint 1 frame ahead of the frame in which the data transfer is scheduled.
- 5. The complete data to be transmitted in the frame must be written into the transmit FIFO (either by the application or the DMA), before the Periodic IN token is received. Even when 1 DWORD of the data to be transmitted per frame is missing in the transmit FIFO when the Periodic IN token is received, the core behaves as when the FIFO was empty. When the transmit FIFO is empty.
- 6. A zero data length packet would be transmitted on the USB for ISO IN endpoints
  - A NAK handshake would be transmitted on the USB for INTR IN endpoints
- 7. For a High Bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be 2\*max\_pkt\_size and have the third packet load in after the first packet has been transmitted on the USB.

#### Internal Data Flow

- 1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
- 2. In Slave mode, the application must also write the required data to the associated transmit FIFO for the endpoint. In DMA mode, the core fetches the data for the endpoint from memory, according to the application setting.
- 3. Every time either the core's internal DMA (in DMA mode) or the application (in Slave mode) writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from DMA or application memory until the transfer size for the endpoint becomes 0.
- 4. When an IN token is received for an periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet) for the frame is not present in the FIFO, then the core generates an IN Token Received When TxFIFO Empty Interrupt for the endpoint.
  - · A zero-length data packet is transmitted on the USB for isochronous IN endpoints
  - · A NAK handshake is transmitted on the USB for interrupt IN endpoints
- 5. The packet count for the endpoint is decremented by 1 under the following conditions:
  - · For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
  - · For interrupt endpoints, when an ACK handshake is transmitted
  - When the transfer size and packet count are both 0, the Transfer Completed interrupt for the endpoint is generated and the endpoint enable is cleared.
- 6. At the "Periodic frame Interval" (controlled by USB\_DCFG.PERFRINT), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates a USB\_GINTSTS.INCOMPISOIN interrupt.

## **Application Programming Sequence (Transfer Per Frame)**

- 1. Program the USB DIEPx TSIZ register. In DMA mode, also program the USB DIEPx DMAADDR register.
- 2. Program the USB DIEPx CTL register with the endpoint characteristics and set the CNAK and Endpoint Enable bits.
- 3. In Slave mode, write the data to be transmitted in the next frame to the transmit FIFO.
- 4. Asserting the USB\_DIEPx\_INT.INTKNTXFEMP (In Token Received When TxFifo Empty) interrupt indicates that either the DMA or application has not yet written all data to be transmitted to the transmit FIFO.
- 5. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
  - If the isochronous endpoint is already enabled when this interrupt is detected, see 15.4.4.2.3.6 Incomplete Isochronous IN Data Transfers for more details.
- 6. The core handles timeouts internally on interrupt IN endpoints programmed as periodic endpoints without application intervention. The application, thus, never detects a USB\_DIEPx\_INT.TIMEOUT interrupt for periodic interrupt IN endpoints.
- 7. Asserting the USB\_DIEPx\_INT.XFERCOMPL interrupt with no USB\_DIEPx\_INT.INTKNTXFEMP (In Token Received When TxFifo Empty) interrupt indicates the successful completion of an isochronous IN transfer. A read to the USB\_DIEPx\_TSIZ register must indicate transfer size = 0 and packet count = 0, indicating all data is transmitted on the USB.
- 8. Asserting the USB\_DIEPx\_INT.XFERCOMPL interrupt, with or without the USB\_DIEPx\_INT.INTKNTXFEMP (In Token Received When TxFifo Empty) interrupt, indicates the successful completion of an interrupt IN transfer. A read to the USB\_DIEPx\_TSIZ register must indicate transfer size = 0 and packet count = 0, indicating all data is transmitted on the USB.
- 9. Asserting the USB\_GINTSTS.INCOMPISOIN (Incomplete Isochronous IN Transfer) interrupt with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.
- 10. For isochronous IN endpoints, see 15.4.4.2.3.6 Incomplete Isochronous IN Data Transfers, for more details.

### 15.4.4.2.3.14 Generic Periodic IN Data Transfers Using the Periodic Transfer Interrupt Feature

This section describes a typical Periodic IN (ISOC / INTR) data transfer with the Periodic Transfer Interrupt feature.

- 1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer is part of a single buffer, and must program the size of that buffer and its start address (in DMA mode) to the endpoint-specific registers.
- 2. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
  - a. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
    - Transfer size[epnum] = n \* mps[epnum] + sp (where n is an integer > 0, and 0 < sp < mps[epnum]. A higher value of n reduces the periodicity of the USB\_DOEPx\_INT.XFERCOMPL interrupt)</li>
    - If (sp > 0), then packet count[epnum] = n + 1. Otherwise, packet count[epnum] = n
  - b. To transmit a single zero-length data packet:
    - Transfer size[epnum] = 0
    - Packet count[epnum] = 1
  - c. To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer in two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
    - First transfer: transfer size[epnum] = n \* mps[epnum]; packet count = n;
    - Second transfer: transfer size[epnum] = 0; packet count = 1;
  - d. The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met.
    - transfer size[epnum] = n \* mps[epnum] + sp (where n is an integer > 0, and 0 < sp < mps[epnum])</li>
    - If (sp > 0), packet count[epnum] = n + 1 Otherwise, packet count[epnum] = n;
    - mc[epnum] = number of packets to be sent out in a frame.
  - e. The application cannot transmit a zero-length data packet at the end of transfer. It can transmit a single zero-length data packet et by itself. To transmit a single zero-length data packet,
    - transfer size[epnum] = 0
    - packet count[epnum] = 1
    - mc[epnum] = packet count[epnum]
- 3. In DMA mode, the core fetches an IN data packet from the memory, always starting at a DWORD boundary. If the maximum packet size of the IN endpoint is not a multiple of 4, the application must arrange the data in the memory with pads inserted at the end of a maximum-packet-size packet so that a new packet always starts on a DWORD boundary.
- 4. Once an endpoint is enabled for data transfers, the core updates the Transfer Size register. At the end of IN transfer, which ended with a Endpoint Disabled interrupt, the application must read the Transfer Size register to determine how much data posted in the transmit FIFO was already sent on the USB.
  - Data fetched into transmit FIFO = Application-programmed initial transfer size core-updated final transfer size
  - Data transmitted on USB = (application-programmed initial packet count Core updated final packet count) \* mps[epnum]
  - Data yet to be transmitted on USB = (Application-programmed initial transfer size data transmitted on USB)
- 5. The application can schedule data transfers for multiple frames, only if multiples of max packet sizes (up to 3 packets), must be transmitted every frame. This is can be done, only when the core is operating in DMA mode.
  - ((n\*USB\_DIEPx\_TSIZ.MC) 1)\*USB\_DIEPx\_CTL.MPS <= USB\_DIEPx\_TSIZ.XFERSIZE <= n\*USB\_DIEPx\_TSIZ.MC\*USB\_DIEPx\_CTL.MPS
  - USB DIEPx TSIZ.PKTCNT = n\*USB DIEPx TSIZ.MC
  - n is the number of frames for which the data transfers are scheduled. Data Transmitted per frame in this case is USB\_DIEPx\_TSIZ.MC\*USB\_DIEPx\_CTL.MPS in all frames except the last one. In frame n, the data transmitted is (USB\_DIEPx\_TSIZ.XFERSIZE (n 1) \* USB\_DIEPx\_TSIZ.MC \* USB\_DIEPx\_CTL.MPS)
- 6. For Periodic IN endpoints, the data must always be prefetched 1 frame ahead for transmission in the next frame. This can be done, by enabling the Periodic IN endpoint 1 frame ahead of the frame in which the data transfer is scheduled.
- 7. The complete data to be transmitted in the frame must be written into the transmit FIFO, before the Periodic IN token is received. Even when 1 DWORD of the data to be transmitted per frame is missing in the transmit FIFO when the Periodic IN token is received, the core behaves as when the FIFO was empty. When the transmit FIFO is empty,
  - · A zero data length packet would be transmitted on the USB for ISOC IN endpoints
  - · A NAK handshake would be transmitted on the USB for INTR IN endpoints
  - USB\_DIEPx\_TSIZ.PKTCNT is not decremented in this case.
- 8. For a High Bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be 2 \* max\_pkt\_size and have the third packet load in after the first packet has been transmitted on the USB.

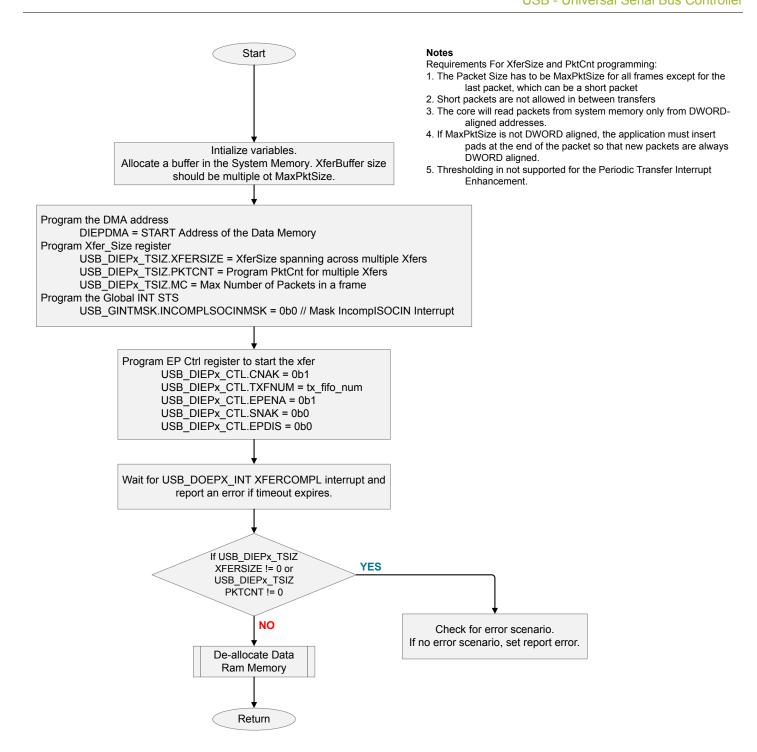

Figure 15.28. Periodic IN Application Flow for Periodic Transfer Interrupt Feature

# 15.4.5 OTG Revision 1.3 Programming Model

This section describes the OTG programming model when the core is configured to support OTG Revision 1.3 of the specification.

The core is an OTG device supporting HNP and SRP. When the core is connected to an "A" plug, it is referred to as an A-device. When the core is connected to a "B" plug it is referred to as a B-device. In Host mode, the core turns off Vbus to conserve power. SRP is a method by which the B-device signals the A-device to turn on Vbus power. A device must perform both data-line pulsing and Vbus pulsing, but a host can detect either data-line pulsing or Vbus pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

### 15.4.5.1 A-Device Session Request Protocol

The application must set the SRP-Capable bit in the Core USB Configuration register. This enables the core to detect SRP as an Adevice.

- 1. To save power, the application suspends and turns off port power when the bus is idle by writing the Port Suspend and Port Power bits in the Host Port Control and Status register.
- 2. PHY indicates port power off by detecting that VBUS voltage level is no longer valid.
- 3. The device must detect SE0 for at least 2 ms to start SRP when Vbus power is off.
- 4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The core detects data-line pulsing.
- 5. The device drives Vbus above the A-device session valid (2.0 V minimum) for Vbus pulsing.

The core interrupts the application on detecting SRP. The Session Request Detected bit is set in Global Interrupt Status register (USB\_GINTSTS.SESSREQINT).

- 6. The application must service the Session Request Detected interrupt and turn on the Port Power bit by writing the Port Power bit in the Host Port Control and Status register. The PHY indicates port power-on by detecting a valid VBUS level.
- 7. When the USB is powered, the device connects, completing the SRP process.

## 15.4.5.2 B-Device Session Request Protocol

The application must set the SRP-Capable bit in the Core USB Configuration register. This enables the core to initiate SRP as a B-device. SRP is a means by which the core can request a new session from the host.

1. To save power, the host suspends and turns off port power when the bus is idle. PHY indicates port power off by detecting a not valid VBUS level.

The core sets the Early Suspend bit in the Core Interrupt register after 3 ms of bus idleness. Following this, the core sets the USB Suspend bit in the Core Interrupt register.

The PHY indicates the end of the B-device session by detecting a VBUS level below session valid.

- 2. PHY to enables the VBUS discharge function to speed up Vbus discharge.
- 3. The PHY indicates the session's end by detecting a session end voltage level on VBUS. This is the initial condition for SRP. The core requires 2 ms of SE0 before initiating SRP.

The application must wait until Vbus discharges to 0.2 V after USB\_GOTGCTL.BSESVLD is deasserted. This discharge time can be obtained from the datasheet.

- 4. The application initiates SRP by writing the Session Request bit in the OTG Control and Status register. The core perform data-line pulsing followed by Vbus pulsing.
- 5. The host detects SRP from either the data-line or Vbus pulsing, and turns on Vbus. The PHY indicates Vbus power-on by detecting a valid VBUS level.
- 6. The core performs Vbus pulsing.

The host starts a new session by turning on Vbus, indicating SRP success. The core interrupts the application by setting the Session Request Success Status Change bit in the OTG Interrupt Status register. The application reads the Session Request Success bit in the OTG Control and Status register.

7. When the USB is powered, the core connects, completing the SRP process.

## 15.4.5.3 A-Device Host Negotiation Protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-Capable bit in the Core USB Configuration register to enable the core to perform HNP as an A#device.

- 1. The core sends the B-device a SetFeature b\_hnp\_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set Host Set HNP Enable bit in the OTG Control and Status register to indicate to the core that the B-device supports HNP.
- 2. When it has finished using the bus, the application suspends by writing the Port Suspend bit in the Host Port Control and Status register.
- 3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.

The core sets the Host Negotiation Detected interrupt in the OTG Interrupt Status register, indicating the start of HNP.

The PHY turns off the D+ and D- pulldown resistors to indicate a device role. The PHY enable the D + pull-up resistor indicates a connect for B-device.

The application must read the Current Mode bit in the OTG Control and Status register to determine Device mode operation.

- 4. The B-device detects the connection, issues a USB reset, and enumerates the core for data traffic.
- 5. The B-device continues the host role, initiating traffic, and suspends the bus when done.

The core sets the Early Suspend bit in the Core Interrupt register after 3 ms of bus idleness. Following this, the core sets the USB Suspend bit in the Core Interrupt register.

- 6. In Negotiated mode, the core detects the suspend, disconnects, and switches back to the host role. The core turns on the D+ and D- pulldown resistors to indicate its assumption of the host role.
- 7. The core sets the Connector ID Status Change interrupt in the OTG Interrupt Status register. The application must read the connector ID status in the OTG Control and Status register to determine the core's operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current Mode bit in the OTG Control and Status register to determine Host mode operation.
- 8. The B-device connects, completing the HNP process.

## 15.4.5.4 B-Device Host Negotiation Protocol

HNP switches the USB host role from B-device to A-device. The application must set the HNP-Capable bit in the Core USB Configuration register to enable the core to perform HNP as a B-device.

1. The A-device sends the SetFeature b\_hnp\_enable descriptor to enable HNP support. The core's ACK response indicates that it supports HNP. The application must set the Device HNP Enable bit in the OTG Control and Status register to indicate HNP support.

The application sets the HNP Request bit in the OTG Control and Status register to indicate to the core to initiate HNP.

- 2. When it has finished using the bus, the A-device suspends by writing the Port Suspend bit in the Host Port Control and Status register.
  - The core sets the Early Suspend bit in the Core Interrupt register after 3 ms of bus idleness. Following this, the core sets the USB Suspend bit in the Core Interrupt register.
  - The core disconnects and the A-device detects SE0 on the bus, indicating HNP. The core enables the D+ and D- pulldown resistors to indicate its assumption of the host role. The A-device responds by activating its D+ pull-up resistor within 3 ms of detecting SE0. The core detects this as a connect.
  - The core sets the Host Negotiation Success Status Change interrupt in the OTG Interrupt Status register, indicating the HNP status. The application must read the Host Negotiation Success bit in the OTG Control and Status register to determine host negotiation success. The application must read the Current Mode bit in the Core Interrupt register (USB\_GINTSTS) to determine Host mode operation.
- 3. The application sets the reset bit (USB\_HPRT.PRTRST) and the core issues a USB reset and enumerates the A-device for data traffic
- 4. The core continues the host role of initiating traffic, and when done, suspends the bus by writing the Port Suspend bit in the Host Port Control and Status register.
- 5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The core disables the D+ and D- pulldown resistors to indicate the assumption of the device role.
- 6. The application must read the Current Mode bit in the Core Interrupt (USB\_GINTSTS) register to determine the Host mode operation
- The core connects, completing the HNP process.

# 15.4.6 OTG Revision 2.0 Programming Model

OTG Revision 2.0 supports the new Attach Detection Protocol (ADP). This protocol enables a local device (an OTG device or Embedded Host) to detect when a remote device is attached or detached.

Note: ADP is not supported by the core.

In addition to ADP, OTG Revision 2.0 also supports enhanced SRP and HNP, which are described in the following sections:

- 15.4.6.1 OTG Revision 2.0 Session Request Protocol
- 15.4.6.2 OTG Revision 2.0 Host Negotiation Protocol

Note: VBUS pulsing is not supported in OTG Revision 2.0 mode.

### 15.4.6.1 OTG Revision 2.0 Session Request Protocol

When the core is behaving as an A-device, it can power off VBUS when no session is active until the B-device initiates a SRP. The SRP detection is handled by the core.

The following figure illustrates the programming steps that need to be performed by A-device's application (core as A-device) when B-device initiates a SRP to establish a connection.

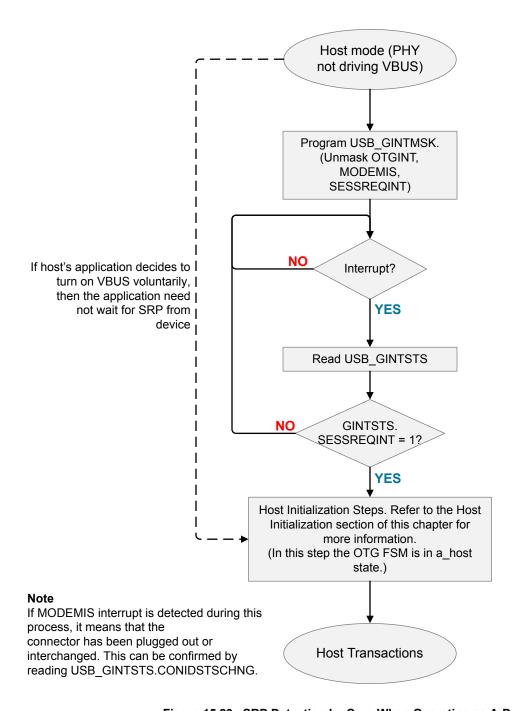

Figure 15.29. SRP Detection by Core When Operating as A-Device

The following figure illustrates the steps that need to be performed by B-device's application (core as B-device) in order to establishing a connection with A-device by signaling a SRP.

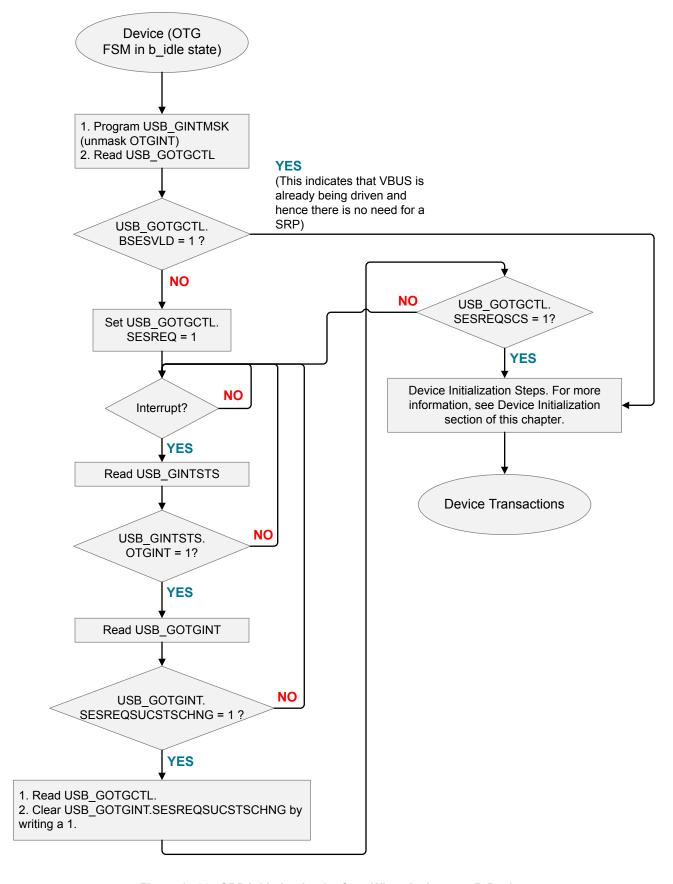

Figure 15.30. SRP Initiation by the Core When Acting as a B-Device

**Note:** The programming flow illustrated in the previous figure is similar to OTG revision 1.3. This is because the presence or absence of VBUS pulsing is transparent to the application.

# 15.4.6.2 OTG Revision 2.0 Host Negotiation Protocol

When the core is operating as A-device, the application must execute a GetStatus() operation to the Bdevice with a frequency of THOST\_REQ\_POLL to determine the state of the host request flag in the B-device. If the host request flag is set in B-device it must program the core to change its role within THOST\_REQ\_SUSP.

The following figure shows the programming steps that need to be performed by A-device's application (core as A-device) in order to change its role to device. In this figure, the A-device performs a role change, becomes a B-device and then reverts back to host (A-device) mode of operation.

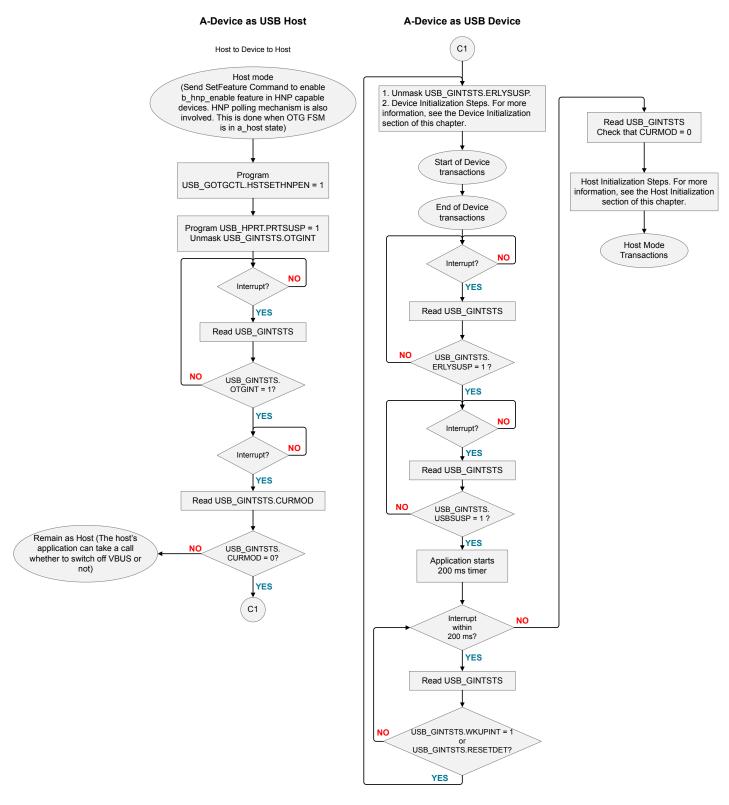

Figure 15.31. HNP When the Core is an A-Device

The following figure shows the programming steps that need to be performed by B-device's application (core as B-device) in order to change its role to Host. In this figure, the B-device performs a role change, becomes a Host and then reverts back to Device mode of operation.

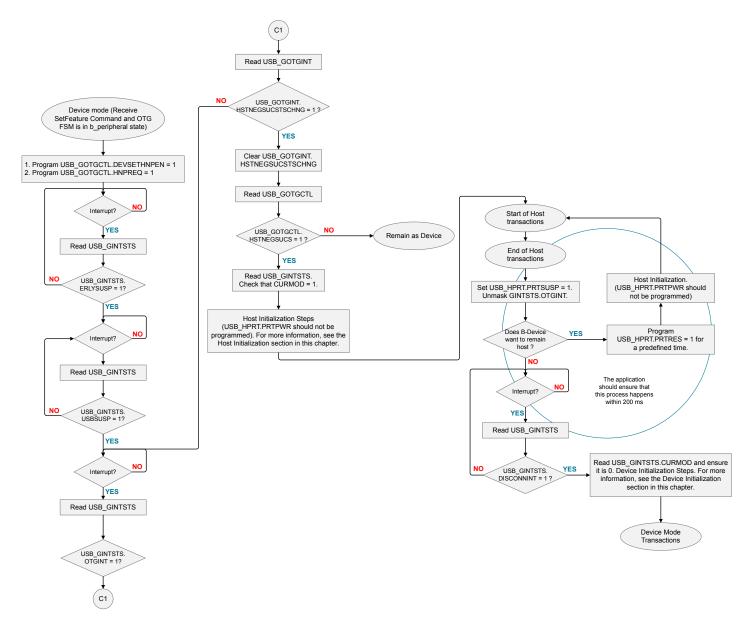

Figure 15.32. HNP When the Core is a B-Device

**Note:** During HNP process where the B-device is going to assume the role of a host, the B-device application needs to ensure that a USB reset process is programmed (in USB\_HPRT register) within 150 ms (TB\_ACON\_BSE0) of getting a USB\_HPRT.PRTCONNDET interrupt.

#### 15.4.7 FIFO RAM Allocation

#### 15.4.7.1 Data FIFO RAM Allocation

External RAM must be allocated among different FIFOs in the core before any transactions can start. The application must follow this procedure every time it changes core FIFO RAM allocation.

The application must allocate data RAM per FIFO based on the AHB's operating frequency, the PHY Clock frequency, the available AHB bandwidth, and the performance required on the USB. Based on the above mentioned criteria, the application must provide a table as described below with RAM sizes for each FIFO in each mode.

The core shares a single FIFO RAM between transmit FIFO(s) and receive FIFO.

In DMA mode—The FIFO RAM is also used for storing the some register information.

The Device mode Endpoint DMA address registers (USB\_DIEP0DMAADDR, USB\_DOEP0DMAADDR, USB\_DIEPx\_DMAADDR, USB\_DOEPx\_DMAADDR) and Host mode Channel DMA registers (USB\_HCx\_DMAADDR) are stored in the FIFO RAM.

This register information are stored at the end of the FIFO RAM after the space allocated for receive and Transmit FIFO. These
register space must also be taken into account when calculating the total FIFO depth of the core as explained in the following sections.

The registers USB DIEPx DMAADDR/USB DOEPx DMAADDR are maintained in RAM.

The following rules apply while calculating how much RAM space must be allocated to store these registers.

### **Host Mode:**

- Slave mode only: No space needed.
- · DMA mode: One location per channel.

#### **Device Mode:**

- · Slave mode only: No space needed.
- · DMA mode: One location per end point direction.

#### 15.4.7.1.1 Device Mode

#### 15.4.7.1.1.1 Tx FIFO Operation

When allocating data RAM for FIFOs in Device mode keep in mind these factors:

- 1. Receive FIFO RAM allocation:
  - RAM for SETUP Packets: 4 \* n + 6 locations must be Reserved in the receive FIFO to receive up to n SETUP packets on control endpoints, where n is the number of control endpoints the device core supports. The core does not use these locations, which are Reserved for SETUP packets, to write any other data.
  - · One location for Global OUT NAK
  - Status information is written to the FIFO along with each received packet. Therefore, a minimum space of (Largest Packet Size / 4) + 1 must be allotted to receive packets. If a high-bandwidth endpoint is enabled, or multiple isochronous endpoints are enabled, then at least two (Largest Packet Size / 4) + 1 spaces must be allotted to receive back-to-back packets. Typically, two (Largest Packet Size / 4) + 1 spaces are recommended so that when the previous packet is being transferred to AHB, the USB can receive the subsequent packet. If AHB latency is high, you must allocate enough space to receive multiple packets. This is critical to prevent dropping any isochronous packets.
  - Along with each endpoint's last packet, transfer complete status information is also pushed to the FIFO. Typically, one location for each OUT endpoint is recommended.
- 2. Transmit FIFO RAM Allocation: The minimum RAM space required for each IN Endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint. More space allocated in the transmit IN Endpoint FIFO results in a better performance on the USB and can hide latencies on the AHB.

Table 15.3. Device Mode FIFO RAM Sizes

FIFO Name	Data RAM Size
Receive data FIFO	rx_fifo_size. This must include RAM for setup packets, OUT end-point control information and data OUT packets, as mentioned earlier.
Transmit FIFO 0	tx_fifo_size[0]
Transmit FIFO 1	tx_fifo_size[1]
Transmit FIFO 2	tx_fifo_size[2]
Transmit FIFO i	tx_fifo_size[i]

With this information, the following registers must be programmed as follows:

- 1. Receive FIFO Size Register (USB GRXFSIZ)
  - USB\_GRXFSIZ.Receive FIFO Depth = rx\_fifo\_size;
- 2. Device IN Endpoint Transmit FIFO0 Size Register (USB\_GNPTXFSIZ)
  - USB GNPTXFSIZ.non-periodic Transmit FIFO Depth = tx fifo size[0];
  - USB\_GNPTXFSIZ.non-periodic Transmit RAM Start Address = rx\_fifo\_size;
- 3. Device IN Endpoint Transmit FIFO#1 Size Register (USB DIEPTXF1)
  - USB\_DIEPTXF1. Transmit RAM Start Address = USB\_GNPTXFSIZ.FIFO0 Transmit RAM Start Address + tx\_fifo\_size[0];
- 4. Device IN Endpoint Transmit FIFO#2 Size Register (USB\_DIEPTXF2)
  - USB DIEPTXF2.Transmit RAM Start Address = USB DIEPTXF1.Transmit RAM Start Address + tx fifo size[1];
- Device IN Endpoint Transmit FIFO#i Size Register (USB\_DIEPTXFi)
  - USB\_DIEPTXFm.Transmit\_RAM\_Start\_Address = USB\_DIEPTXFi-1.Transmit\_RAM\_Start\_Address + tx\_fifo\_size[i-1];
- 6. The transmit FIFOs and receive FIFO must be flushed after the RAM allocation is done, for the proper functioning of the FIFOs.
  - USB GRSTCTL.TXFNUM = 0x10
  - USB\_GRSTCTL.TXFFLSH = 1
  - USB GRSTCTL.RXFFLSH = 1

The application must wait until the TXFFLSH bit and the RXFFLSH bits are cleared before performing any operation on the core.

#### 15.4.7.1.2 Host Mode

Considerations for allocating data RAM for Host Mode FIFOs are listed here:

### **Receive FIFO RAM Allocation**

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of (Largest Packet Size / 4) + 2 must be allotted to receive packets. If a high-bandwidth channel is enabled, or multiple isochronous channels are enabled, then at least two (Largest Packet Size / 4) + 2 spaces must be allotted to receive back-to-back packets. Typically, two (Largest Packet Size / 4) + 2 spaces are recommended so that when the previous packet is being transferred to AHB, the USB can receive the subsequent packet. If AHB latency is high, you must allocate enough space to receive multiple packets.

Along with each host channel's last packet, information on transfer complete status and channel halted is also pushed to the FIFO. So two locations must be allocated for this.

For handling NAK in DMA mode, the application must determine the number of Control/Bulk OUT endpoint data that must fit into the TX FIFO at the same instant. Based on this, one location each is required for Control/Bulk OUT endpoints.

For example, when the host addresses one Control OUT endpoint and three Bulk OUT endpoints, and all these must fit into the non-periodic TX\_FIFO at the same time, then four extra locations are required in the RX FIFO to store the rewind status information for each of these endpoints.

# **Transmit FIFO RAM Allocation**

The minimum amount of RAM required for the Host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB and can hide AHB latencies. Typically, two Largest Packet Sizes' worth of space is recommended, so that when the current packet is under transfer to the USB, the AHB can get the next packet. If the AHB latency is large, then you must allocate enough space to buffer multiple packets.

The minimum amount of RAM required for Host periodic Transmit FIFO is the largest maximum packet size among all supported periodic OUT channels. If there is at lease one High Bandwidth Isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

### 15.4.7.1.2.1 Internal Register Storage Space Allocation

When operating in DMA mode, the DMA address register for each host channel (USB\_HCx\_DMAADDR) is stored in the FIFO RAM. One location for each channel must be reserved for this.

Table 15.4. Host Mode FIFO RAM Sizes

FIFO Name	Data RAM Size
Receive Data FIFO	rx_fifo_size
Non-periodic Transmit FIFO	tx_fifo_size[0]
IN Endpoint Transmit FIFO	tx_fifo_size[1]

With this information, the following registers must be programmed:

- 1. Receive FIFO Size Register (USB GRXFSIZ)
  - USB\_GRXFSIZ.RXFDEP = rx\_fifo\_size;
- 2. Non-periodic Transmit FIFO Size Register (USB GNPTXFSIZ)
  - USB\_GNPTXFSIZ.NPTXFDEP = tx\_fifo\_size[0];
  - USB GNPTXFSIZ.NPTXFSTADDR = rx fifo size;
- 3. Host Periodic Transmit FIFO Size Register (USB\_HPTXFSIZ)
  - USB HPTXFSIZ.PTXFSIZE = tx fifo size[1];
  - USB\_HPTXFSIZ.PTXFSTADDR = USB\_GNPTXFSIZ.NPTXFSTADDR + tx\_fifo\_size[0];
- 4. The transmit FIFOs and receive FIFO must be flushed after RAM allocation for proper FIFO function.
  - USB GRSTCTL.TXFNUM = 0x10
  - USB GRSTCTL.TXFFLSH = 1
  - USB GRSTCTL.RXFFLSH = 1

The application must wait until the TXFFLSH bit and the RXFFLSH bits are cleared before performing any operation on the core.

# 15.4.7.1.3 Summary of Guidelines for Choosing Data FIFO RAM Depth in Host Mode

### 15.4.7.1.3.1 RX FIFO Size

The RX FIFO size must be equal to at least twice the largest value of MPS size used. The recommended minimum RXFIFO depth = ((largest packet size/4)\*2)+2. (+2) is required by the core for the status quadlets internally.

## 15.4.7.1.3.2 Non Periodic TX FIFO Size

This should be equal to at least twice the largest value of MPS size used. The recommended minimum non-periodic TXFIFO depth = ((largest packet size/4)\*2).

### 15.4.7.1.3.3 Periodic TX FIFO Size

The recommended size for Periodic TXFIFO is sum total of (MPS\*MC)/4 for all the channels.

**Note:** In the above recommendations, always round off the MPS value to the nearest multiple of 4. For example, if the largest value of MPS=125, use the rounded-off value, which is 128.

### 15.4.7.1.4 Calculating the Total FIFO Size

The RxFIFO is shared between the host and device. The Host TxFIFOs are also shared with Device IN endpoint TxFIFOs 0 through n.

There are three ways to calculate the total FIFO size.

### Method 1

Use this method if you are using the following conditions:

- · Minimum FIFO depth allocation
- · The FIFO must equal at least one MaxPacketSize (MPS).

Device RxFIFO =

 (4 \* number of control endpoints + 6) + ((largest USB packet used / 4) + 1 for status information) + (2 \* number of OUT endpoints) + 1 for Global NAK

Note: Include the Control OUT endpoint in the number of OUT endpoints.

Host RxFIFO =

· Slave mode

Minimum requirement: (largest USB packet used / 4) + 1 for status information + 1 transfer complete

• DMA mode

(largest USB packet used / 4) + 1 for status information + 1 transfer complete + 1 location each bulk/ control out endpoint for handling NAK scenario

Host Non-Periodic TxFIFO =

· largest non-periodic USB packet used / 4

Host Periodic TxFIFO =

Sum total of (MPS\*MC)/4 of all periodic channels or 1500 locations, whichever is lower.

Device IN Endpoint TxFIFOs (a separate FIFO is allocated to each IN endpoint) =

· IN Endpoints Max packet Size / 4

# Method 2

Use this method if you are using the recommended minimum FIFO depth allocation with support for high-bandwidth endpoints. This FIFO allocation enables the core to transfer a packet on the USB while the previous (next) packet is simultaneously transferred to the AHB. This FIFO allocation improves the core's performance.

Device RxFIFO =

(4 \* number of control endpoints + 6) + 2 \* ((largest USB packet used / 4) + 1) + (2 \* number of OUT endpoints) + 1

Host RxFIFO =

- · Slave mode
  - 2 \* ((largest USB packet used / 4) + 1 + 1)
- · DMA mode
  - 2 \* ((largest USB packet used / 4) + 1 + 1) + 1 location each bulk/control out endpoint for handling NAK scenario

Host Non-Periodic TxFIFO =

• 2 \* (largest non-periodic USB packet used / 4)

Host Periodic TxFIFO =

Sum total of (MPS\*MC)/4 for all periodic channels or 1500 location, whichever is lower.

Device IN Endpoint-Specific TxFIFOs (a separate FIFO is allocated to each endpoint) =

• 2 \* (max\_pkt\_size for the endpoint) / 4.

```
//DMA mode
OTG Total RAM = (Device RxFIFO or Host RxFIFO; choose the largest one) +((Host Non-Periodic TxFIFO + Host peiod ic TxFIFO) or
(Device IN Endpoint TxFIFO #0 + #1 + #2 + #n)); choose the largest one +
(1 location per Host channel or 1 location per Device Endpoint direction; choose the largest one)
//Slave mode
OTG Total RAM = (Device RxFIFO or Host RxFIFO; choose the largest one) +
((Host Non-Periodic TxFIFO + Host peiodic TxFIFO) or
(Device IN Endpoint TxFIFO #0 + #1 + #2 + #n)); choose the largest one
```

#### Method 3

Use this method if you are using the recommended FIFO depth allocation that supports high-bandwidth endpoints and high AHB latency.

#### Note:

- x = (AHB latency + time to transfer largest packet on AHB) / time to transfer largest packet on USB.
- The value of x is an integer. Any fractional value is rounded to the nearest integer. For example: x = 20 ms / 17,039 ms = 1.17 ms = 2 ms.

Device RxFIFO =

• (4 \* number of control endpoints + 6) + (x + 1) \* ((largest USB packet used / 4) + 1) + (2 \* number of OUT endpoints) + 1

Note: Include the Control OUT endpoint in the number of OUT endpoints.

Host RxFIFO =

· Slave mode

```
(x + 1) * ((largest USB packet used / 4) + 1 + 1)
```

· DMA mode

(x + 1) \* ((largest USB packet used / 4) + 1 + 1) + 1 location each bulk/control out endpoint for handling NAK scenario

Host Non-Periodic TxFIFO =

(x + 1) \* (largest non-periodic USB packet used / 4)

Host Periodic TxFIFO =

(x+1) \* (Sum total of (MPS\*MC)/4 of all periodic channels or 1500 locations, whichever is lower).

Device IN Endpoint-Specific TxFIFOs (a separate FIFO is allocated to each endpoint) =

(x+1)\*(max\_pkt\_size for the endpoint)/4

```
//DMA mode
OTG Total RAM = (Device RxFIFO or Host RxFIFO; choose the largest one) +
((Host Non-Periodic TxFIFO + Host periodic TxFIFO) OR
(Device IN Endpoint TxFIFO #0 + #1 + #2 + #n); choose the largest one) +
(1 location per Host channel or 1 location per Device Endpoint direction; choose the largest one)
//Slave mode
OTG Total RAM = (Device RxFIFO or Host RxFIFO; choose the largest one) +
((Host Non-Periodic TxFIFO + Host periodic TxFIFO) OR
(Device IN Endpoint TxFIFO #0 + #1 + #2 + #n); choose the largest one)
```

## 15.4.7.2 Dynamic FIFO Allocation

The application can change the RAM allocation for each FIFO during the operation of the core.

### 15.4.7.2.1 Host Mode

In Host mode, before changing FIFO data RAM allocation, the application must determine the following.

All channels are disabled

· All FIFOs are empty

Once these conditions are met, the application can reallocate FIFO data RAM as explained in 15.4.7.1 Data FIFO RAM Allocation.

After reallocating the FIFO data RAM, the application must flush all FIFOs in the core using the USB\_GRSTCTL.TXFFLSH (TxFIFO Flush) and USB\_GRSTCTL.RXFFLSH (RxFIFO Flush) fields. Flushing is required to reset the pointers in the FIFOs for proper FIFO operation after reallocation. For more information on flushing FIFOs, see 15.4.7.2.3 Flushing TxFIFOs in the Core and 15.4.7.2.4 Flushing RxFIFOs in the Core.

#### 15.4.7.2.2 Device Mode

In Device mode, before changing FIFO data RAM allocation, the application must determine the following.

- · All IN and OUT endpoints are disabled
- · NAK mode is enabled in the core on all IN endpoints
- · Global OUT NAK mode is enabled in the core
- · All FIFOs are empty

Once these conditions are met, the application can reallocate FIFO data RAM as explained in 15.4.7.1 Data FIFO RAM Allocation. When NAK mode is enabled in the core, the core responds with a NAK handshake on all tokens received on the USB, except for SET-UP packets.

After the reallocating the FIFO data RAM, the application must flush all FIFOs in the core using the USB\_GRSTCTL.TXFFLSH (TxFIFO Flush) and USB\_GRSTCTL.RXFFLSH (RxFIFO Flush) fields. Flushing is required to reset the pointers in the FIFOs for proper FIFO operation after reallocation. For more information on flushing FIFOs, see 15.4.7.2.3 Flushing TxFIFOs in the Core and 15.4.7.2.4 Flushing RxFIFOs in the Core.

### 15.4.7.2.3 Flushing TxFIFOs in the Core

The application can flush all TxFIFOs in the core using USB\_GRSTCTL.TXFFLSH as follows:

- 1. Check that USB\_GINTSTS.GINNAKEFF=0. If this bit is cleared then set USB\_DCTL.SGNPINNAK=1.
- 2. Wait for USB\_GINTSTS.GINNAKEFF=1, which indicates the NAK setting has taken effect to all IN endpoints.
- 3. Poll USB\_GRSTCTL.AHBIDLE until it is 1.

AHBIdle = H indicates that the core is not writing anything to the FIFO.

- 4. Check that USB\_GRSTCTL.TXFFLSH =0. If it is 0, then write the TxFIFO number you want to flush to USB\_GRSTCTL.TXFNUM.
- 5. Set USB GRSTCTL.TXFFLSH=1and wait for it to clear.
- 6. Set the USB DCTL.GCNPINNAK bit.

## 15.4.7.2.4 Flushing RxFIFOs in the Core

The application can flush all RxFIFOs in the core using USB\_GRSTCTL.RXFFLSH as follows:

- 1. Check the status of the USB\_GINTSTS.GOUTNAKEFF bit. If it has been cleared, then set USB\_DCTL.SGOUTNAK=1. Else, clear USB\_GINTSTS.GOUTNAKEFF.
  - NAK Effective interrupt = 1 indicates that the core is not writing to FIFO.
- 2. Wait for USB\_GINTSTS.GOUTNAKEFF=1, which indicates the NAK setting has taken effect to all OUT endpoints.
- 3. Poll the USB\_GRSTCTL.AHBIDLE until it is 1.
  - AHBIDLE = 1 indicates that the core is not reading anything from the FIFO.
- 4. Set USB\_GRSTCTL.RXFFLSH=1 and wait for it to clear.
- 5. Set the USB\_DCTL.GCOUTNAK bit.

#### 15.4.8 Suspend/Resume and SRP

This chapter describes different methods of saving power when the USB is suspended. This chapter discusses the following topics:

- 15.4.8.1 Placing PHY in Low Power Mode Without Entering Suspend
  - 15.4.8.1.1 When the Core is in Host Mode
  - 15.4.8.1.2 When the Core is in Device Mode
- 15.4.8.2 Suspend
  - 15.4.8.2.1 Using EM2
    - 15.4.8.2.1.1 Overview of the EM2 Programming Model
    - 15.4.8.2.1.2 EM2 When the Core is in Host Mode
    - 15.4.8.2.1.3 EM2 When the Core is in Device Mode
- 15.4.8.2.2 Using Clock Gating in EM0/EM1
  - 15.4.8.2.2.1 Internal Clock Gating when the Core is in Host Mode
  - 15.4.8.2.2.2 Internal Clock Gating when the Core is in Device Mode

## 15.4.8.1 Placing PHY in Low Power Mode Without Entering Suspend

The core can place the PHY in low power mode (the differential receiver is disabled) without entering suspend.

#### 15.4.8.1.1 When the Core is in Host Mode

### Programming Flow for the Host Core to Put PHY in Low Power Mode

- 1. To turn off port power, perform write operation to set the following bits in the USB HPRT register:
  - USB HPRT.PRTPWR = 0;
  - USB HPRT.PRTENA = 0;
- 2. To put PHY in low power mode, perform read-modify-write operation to set the following bits in the USB\_PCGCCTL register:
  - USB PCGCCTL.STOPPCLK = 1
  - USB PCGCCTL.GATEHCLK = 0

# Programming Flow for the Host Core to Make PHY Exit Low Power Mode

If your device is non-SRP capable, the host must implement polling to detect the device connection by turning on the port and exiting PHY low power mode periodically and checking for connect.

- 1. To turn on port power, perform write operation to set the following bits in the USB HPRT register:
  - USB\_HPRT.PRTPWR = 1
  - USB HPRT.PRTENA = 0
- 2. To exit PHY low power mode, perform read-modify-write operation to set the following bits in the USB PCGCCTL register:
  - USB\_PCGCCTL.STOPPCLK = 0
  - USB PCGCCTL.STOPHCLK = 0
- 3. Wait for the USB\_HPRT Port Connect Detected (PRTCONNDET) bit to be set and do the enumeration of the device.

If your device is SRP-capable, when the device initiates SRP request, the Host core asynchronously detects SRP and the PHY exits low power mode.

- Wait for Session Request from the device, or New Session Detected Interrupt (SESSREQINT) in the USB GINTSTS register.
- 2. To turn on port power, perform write operation to set the following bits in the USB\_HPRT register:
  - USB HPRT.PRTPWR = 1
  - USB HPRT.PRTENA = 0
- 3. Wait for the USB HPRT Port Connect Detected (PRTCONNDET) bit to be set and do the enumeration of Device.

### 15.4.8.1.2 When the Core is in Device Mode

To make PHY enter low power mode, complete the following steps:

- 1. Ensure that the following signals are set as follows:
  - · VBUS voltage level must be below the session valid level (VBUS is not active)
  - DP/DM must be SE0
- 2. From the application, perform read-modify-write operation to set USB\_PCGCCTL.STOPPCLK = 1.

## 15.4.8.2 Suspend

When the core is in Suspend, the following power conservation options are available to use:

- 15.4.8.2.1 Using EM2 You can enter EM2, turning off power (and reseting) parts of the core
- 15.4.8.2.2 Using Clock Gating in EM0/EM1 You can choose gate the AHB clock to some parts of the core

This section discusses methods of conserving power by using one of the above methods.

## 15.4.8.2.1 Using EM2

## 15.4.8.2.1.1 Overview of the EM2 Programming Model

When the USB is suspended or the session is not valid, the PHY is driven into Suspend mode, stopping the PHY clock to reduce power consumption in the PHY and the core. To further reduce power consumption, the core also supports AHB clock gating and using EM2.

The following sections show the procedures you must follow to use EM2 while in suspend/session-off.

During EM2, the clock to the core must be switched to one of the 32 kHz sources (LFRCO or LFXO). This core needs this clock to detect Resume and SRP events.

#### 15.4.8.2.1.2 EM2 When the Core is in Host Mode

#### **Host Mode Suspend in EM2**

Sequence of operations:

- 1. Back up the essential registers of the core. Read and store the following core registers:
  - USB\_GINTMSKUSB\_DAINTMSK
  - USB GOTGCTL USB DIEPMSK
  - USB\_GAHBCFGUSB\_DOEPMSK
  - USB\_GUSBCFGUSB\_DIEPx\_CTL
  - USB GRXFSIZ USB DIEPx TSIZ
  - USB\_GNPTXFSIZ USB\_DIEPx\_DMAADDR
  - USB\_DCFG USB\_PCGCCTL
  - USB DCTL USB DIEPTXFn
- The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
- The application sets the Power Clamp bit in the Power and Clock Gating Control register.
- 4. The application sets the Reset to Power-Down Modules bit in the Power and Clock Gating Control register.
- 5. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core suspends the PHY and the PHY clock stops. If USB\_HCFG.ENA32KHZS is set, switch the USBC clock to 32 kHz.
- 6. Enter EM2.

### **Host Mode Resume in EM2**

Sequence of operations:

- 1. The resume event starts by the application waking up from EM2 (on an interrupt)
- 2. Switch USBC clock back to 48 MHz.
- 3. The application clears the Stop PHY Clock bit and the core takes the PHY back to normal mode. The PHY clock starts up.
- 4. The application clears the Power Clamp bit. The core starts driving Resume signaling on the USB.
- 5. The application clears the Reset to Power-Down Modules bit.
- 6. The application programs registers in the CSR and sets the Port Resume bit in Host Port CSR (Setting the Port Resume bit is required by the core, although Resume signaling starts earlier).
- 7. The application clears the Port Resume bit and the core stops driving Resume signaling.

The core is in normal operating mode.

**Note:** The application must insert delays of at least 2 PHY clocks between all steps in this sequence. This requirement applies to all USB EM2 programming sequences.

## **Host Mode Remote Wakeup in EM2**

Sequence of operations:

- 1. The core detects Remote Wakeup signaling on the USB. The PHY exits suspend mode and the PHY clock restarts.
- 2. The core generates a Remote Wakeup Detected interrupt. The Remote Wakeup interrupt is generated using the 32 kHz clock depending on the USB HCFG.RESVALID (ResumeValidPeriod) programmed. The Host Core starts resume signaling at this stage.
- 3. The USBC clock is switched back to normal 48 MHz clock.
- 4. The application clears the Stop PHY Clock bit.
- 5. The application clears the Power Clamp bit.
- 6. The application clears the Reset to Power-Down Modules bit
- 7. The application programs CSRs and sets the Port Resume bit. The core continues to drive Resume signaling on the USB.
- 8. The application clears the Port Resume bit and the core stops driving Resume signaling.

The core enters normal operating mode.

#### Host Mode Session End in EM2

Sequence of operations:

1. Back up the essential registers of the core. Read and store the following core registers:

```
USB_GINTMSKUSB_DAINTMSKUSB_GOTGCTLUSB_DIEPMSK
```

• USB\_GAHBCFG • USB\_DOEPMSK

• USB\_GUSBCFG • USB\_DIEPx\_CTL

• USB\_GRXFSIZ • USB\_DIEPx\_TSIZ

• USB\_GNPTXFSIZ • USB\_DIEPx\_DMAADDR

USB\_DCFGUSB\_DCTLUSB\_DIEPTXFn

- 2. The application sets the Port Suspend bit in the Host Port CSR and the core drives a USB suspend.
- 3. The application clears the Port Power bit.
- 4. The application sets the Power Clamp bit in the Power and Clock Gating Control register, and the core clamps the signals between the internal modules on different power rails.
- The application sets the Reset to Power-Down Modules bit in the Power and Clock Gating Control register.
- The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, and the core suspends the PHY, stopping the PHY clock.
- 7. Switch USBC clock to 32 kHz.
- 8. Enter EM2.

## **Host Mode Session Start (EM2 -> EM0)**

Sequence of operations:

- 1. Exit EM2/Enter EM0).
- 2. Switch USBC clock back to 48 MHz.
- 3. The application clears the Stop PHY Clock bit.
- 4. The application clears the Power Clamp bit. The application clears the Reset to Power-Down Modules bit.
- 5. The application programs CSRs and sets the Port Power bit to turn on VBUS.
- 6. The core detects the connection and drives the USB reset.

The core enters normal operating mode.

## Host Mode Session End (EM0 -> EM2)

Sequence of operations:

- 1. Back up the essential registers of the core. Read and store the following core registers:
  - USB\_GINTMSK USB\_DAINTMSK
  - USB GOTGCTL USB DIEPMSK
  - USB\_GAHBCFG USB\_DOEPMSK
  - USB\_GUSBCFG USB\_DIEPx\_CTL
  - USB GRXFSIZ USB DIEPx TSIZ
  - · USB GNPTXFSIZ · USB DIEPx DMAADDR
  - USB DCFG
     USB PCGCCTL
  - USB DCTL
- 2. The application sets the Port Suspend bit in the Host Port CSR and the core drives a USB suspend.
- 3. The application clears the Port Power bit.

- 4. The application sets the Power Clamp bit in the Power and Clock Gating Control register, and the core clamps the signals between the internal modules on different power rails.
- 5. The application sets the Reset to Power-Down Modules bit in the Power and Clock Gating Control register.
- 6. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register.
- 7. Enter EM2.

### Host Mode Sessions Start (SRP) (EM2 -> EM0)

### Sequence of operations:

- 1. The core detects SRP (data line pulsing) on the bus. The core de-asserts the suspend\_n signal to the PHY, generating the PHY clock. The SRP Detected interrupt is generated.
- 2. The application clears the Stop PHY Clock bit, the core deasserts the suspend\_n signal to the PHY to generate the PHY clock.
- 3. The power (VDD DN) is turned on and stabilizes.
- 4. The application clears the Power Clamp bit.
- 5. The application clears the Reset to Power-Down Modules bit.
- 6. The application programs the CSRs, and sets the Port Power bit to turn on VBUS.
- 7. The core detects device connection and drives a USB reset.

The core enters normal operating mode.

#### 15.4.8.2.1.3 EM2 When the Core is in Device Mode

#### **Device Mode Suspend With EM2**

In Device mode, the device validates the host-driven Resume signal for a period of 1.5  $\mu$ s (75 clock cycles at 48 MHz). With a 32-KHz clock, 2.34 ms is required (75 clock cycles at 32 KHz) to detect the resume. Hence, the application programs USB\_DCFG.RESVALID with a value of 4 clock cycles (125  $\mu$ s). If the core is in Suspend mode, the device thus detects the resume and the host signals a resume for a minimum of 125  $\mu$ s.

If the device is being reset from suspend, it begins a high-speed detection handshake after detecting SE0 for no fewer than 2.5 μs. With a 48-MHz clock, detection occurs after 120 clock cycles (2.5 μs). With a 32-kHz clock, 120 clock cycles signifies 3.75 msec. Hence, a programmable value of 4 clock cycles (125 μs) is used to detect reset.

The 32-KHz Suspend feature incorporates switching to the 32-KHz clock during suspend and resume/ remote wakeup until the system comes up and starts driving 48 MHz.

### Sequence of operations:

- 1. Detect Suspend state. Wait for an interrupt from the device core and check that USB GINTSTS.USBSUSP is set to 1.
- 2. Back up the essential registers of the core. Read and store the following core registers:
  - USB GINTMSK
     USB DAINTMSK
  - USB\_GOTGCTLUSB\_DIEPMSK
  - USB\_GAHBCFGUSB\_DOEPMSK
  - USB\_GUSBCFG
     USB\_DIEPx\_CTL
  - USB\_GRXFSIZUSB\_DIEPx\_TSIZ
  - USB\_GNPTXFSIZ USB\_DIEPx\_DMAADDR
  - USB DCFG
     USB PCGCCTL
  - USB DCTL USB DIEPTXFn
- 3. The application sets the PWRCLMP bit in the Power and Clock Gating Control (USB\_PCGCCTL) register.
- 4. The application sets the USB\_PCGCCTL.RSTPDWNMODULE bit.
- 5. The application sets the USB PCGCCTL.STOPPCLK bit.
- 6. Switch USB Core Clock (USBC) to 32 kHz.
- 7. Enter EM2.

### Device Mode Resume (EM2 -> EM0)

#### Sequence if operations:

- 1. The core detects Resume signaling on the USB. The core generates a Resume Detected interrupt.
- 2. Switch USB Core Clock (USBC) back to 48 MHz.
- 3. The application clears the STOPPCLK bit.
- 4. The application clears the USB\_PCGCCTL.PWRCLMP and USB\_PCGCCTL.RSTPDWNMODULE bits.
- 5. Restore the USB GUSBCFG and USB DCFG registers with the values stored during the Save operation before entering EM2.
- 6. Restore the following core registers with the values stored during the Save operation before entering EM2:
  - USB GINTMSK
     USB DIEPMSK
  - USB GOTGCTL USB DOEPMSK
  - USB\_GUSBCFGUSB\_DIEPx\_CTL
  - USB GRXFSIZ
     USB DIEPx TSIZ
  - USB GNPTXFSIZ USB DIEPx DMAADDR
  - USB\_DAINTMSKUSB\_DIEPTXFn
- 7. The application programs CSRs, then sets the Power-On Programming Done bit in the Device Control register.

#### Device Mode Remote Wakeup (EM2 -> EM0)

Sequence if operations:

- An interrupt wakes up the device from EM2.
- 2. Switch USB Core Clock (USBC) back to 48 MHz.
- 3. The application clears the STOPPCLK and GATEHCLK bits in the USB\_PCGCCTL register.
- 4. The application clears the USB PCGCCTL.PWRCLMP and USB PCGCCTL.RSTPDWNMODULE bits.
- 5. Restore the USB\_GUSBCFG and USB\_DCFG registers with the values stored during the Save operation before entering EM2.
- 6. Drive remote wakeup from the core. Program USB DCTL by performing write-only operation with the following values:
  - USB DCTL.RMTWKUPSIG = 1
  - Other Bits = Value stored during the Save operation before entering EM2
- 7. Clear all interrupt status. Wait for at least 1 millisecond of remote wakeup time and then program GINSTS register with 0xFFFFFFF to clear all the status register fields.
- 8. Restore the following core registers with the values stored during the Save operation before entering EM2:
  - USB\_GINTMSK USB\_DIEPMSK
  - USB GOTGCTL USB DOEPMSK
  - · USB GUSBCFG · USB DIEPx CTL
  - USB GRXFSIZ USB DIEPx TSIZ
  - · USB GNPTXFSIZ · USB DIEPx DMAADDR
  - USB DAINTMSK
     USB DIEPTXFn
- 9. Wait for remote wakeup time (1-15ms) and then program USB\_DCTL by performing read-modify-write to set USB\_DCTL.RMTWKUPSIG = 0.

#### Device Mode Session End (EM0 -> EM2)

Sequence of operations:

- 1. The core detects a USB suspend and generates a Suspend Detected interrupt. The host turns off VBUS.
- 2. The application sets the Power Clamp bit in the Power and Clock Gating Control register.
- 3. The application sets the Reset to Power-Down Modules bit in the Power and Clock Gating Control register.
- 4. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register.
- 5. Switch USB Core clock (USBC) to 32 kHz.
- 6. Enter EM2.

#### Device Mode Session Start (EM2 -> EM0)

Sequence of operations:

- 1. The core detects VBUS on (voltage level within session-valid). A New Session Detected interrupt is generated.
- 2. Switch USB Core clock (USBC) back to 48 MHz.
- 3. The application clears the Stop PHY Clock bit.
- 4. The application clears the Power Clamp bit.
- 5. The application clears the Reset to Power-Down Modules bit.
- 6. The application programs CSRs.
- 7. The cores detects a USB reset.

The core enters normal operating mode.

### 15.4.8.2.2 Using Clock Gating in EM0/EM1

The core supports HCLK gating to reduce dynamic power to internal modules to the core during Suspend/ session-off state in EM0 and EM1.

#### 15.4.8.2.2.1 Internal Clock Gating when the Core is in Host Mode

The following sections show the procedures you must follow to use the clock gating feature.

### Host Mode Suspend and Resume With Clock Gating

#### Sequence of operations:

- 1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, the core gates the hclk internally.
- 3. The core remains in Suspend mode.
- 4. The application clears the Gate hclk and Stop PHY Clock bits, and the PHY clock is generated.
- 5. The application sets the Port Resume bit, and the core starts driving Resume signaling.
- 6. The application clears the Port Resume bit after at least 20 ms.
- 7. The core is in normal operating mode.

#### Host Mode Suspend and Remote Wakeup With Clock Gating

#### Sequence of operations:

- 1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates hclk internally.
- 3. The core remains in Suspend mode.
- 4. The Remote Wakeup signaling from the device is detected. The core generates a Remote Wakeup Detected interrupt.
- 5. The application clears the Gate hclk and Stop PHY Clock bits. The core sets the Port Resume bit.
- 6. The application clears the Port Resume bit after at least 20 ms.
- 7. The core is in normal operating mode.

## Host Mode Session End and Start With Clock Gating

### Sequence of operations:

- 1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
- 2. The application clears the Port Power bit. The core turns off VBUS.
- 3. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates hclk internally.
- 4. The core remains in Low-Power mode.
- 5. The application clears the Gate hclk bit and the application clears the Stop PHY Clock bit to start the PHY clock.
- The application sets the Port Power bit to turn on VBUS.
- 7. The core detects device connection and drives a USB reset.
- 8. The core is in normal operating mode.

### Host Mode Session End and SRP With Clock Gating

#### Sequence of operations:

- 1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
- 2. The application clears the Port Power bit. The core turns off VBUS.
- 3. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates hclk internally.
- 4. The core remains in Low-Power mode.
- SRP (data line pulsing) from the device is detected. An SRP Request Detected interrupt is generated.
- 6. The application clears the Gate hclk bit and the Stop PHY Clock bit.
- 7. The core sets the Port Power bit to turn on VBUS.
- 8. The core detects device connection and drives a USB reset.
- 9. The core is in normal operating mode.

### 15.4.8.2.2.2 Internal Clock Gating when the Core is in Device Mode

The following sections show the procedures you must follow to use the clock gating feature.

#### **Device Mode Suspend and Resume With Clock Gating**

#### Sequence of operations:

- 1. The core detects a USB suspend and generates a Suspend Detected interrupt.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates hclk.
- 3. The core remains in Suspend mode.
- 4. The Resume signaling from the host is detected. A Resume Detected interrupt is generated.
- 5. The application clears the Gate hclk bit and the Stop PHY Clock bit.
- 6. The host finishes Resume signaling.
- 7. The core is in normal operating mode.

#### **Device Mode Suspend and Remote Wakeup With Clock Gating**

#### Sequence of operations:

- 1. The core detects a USB suspend and generates a Suspend Detected interrupt.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, the core gates hclk.
- 3. The core remains in Suspend mode.
- 4. The application clears the Gate hclk bit and the Stop PHY Clock bit.
- 5. The application sets the Remote Wakeup bit in the Device Control register, the core starts driving Remote Wakeup signaling.
- The host drives Resume signaling.
- 7. The core is in normal operating mode.

### Device Mode Session End and Start With Clock Gating

#### Sequence of operations:

- 1. The core detects a USB suspend, and generates a Suspend Detected interrupt. The host turns off VBUS.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates hclk.
- 3. The core remains in Low-Power mode.
- 4. The new session is detected (A session-valid voltage is detected). A New Session Detected interrupt is generated.
- 5. The application clears the Gate hclk and Stop PHY Clock bits.
- 6. The core detects USB reset.
- 7. The core is in normal operating mode.

## **Device Mode Session End and SRP With Clock Gating**

### Sequence of operations:

- 1. The core detects a USB suspend, and generates a Suspend Detected interrupt. The host turns off VBUS.
- 2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates hclk.
- 3. The core remains in Low-Power mode.
- 4. The application clears the Gate hclk and Stop PHY Clock bits.
- 5. The application sets the SRP Request bit, and the core drives data line and VBUS pulsing.
- 6. The host turns on VBUS, detects device connection, and drives a USB reset.
- 7. The core is in normal operating mode.

#### 15.4.9 Register Usage

Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessed in both Host and Device modes. When the core is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (USB\_GINTSTS.MO-DEMIS).

When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset.

The memory map for the core is as follows:

- Core Global Registers are located in the address offset-range [0x3C000, 0x3C3FF] and typically start with first letter G.
- Host Mode Registers are located in the address offset-range [0x3C400, 0x3C7FF] and start with first letter H.
- Device Mode Registers are located in the address offset-range [0x3C800, 0x3CDFF] and start with first letter D.
- The Power and Clock Gating register is located at offset 0x3CE00.
- The Device EP/Host Channel FIFOs start at address offset 0x3D000 with 4K spacing. These registers, available in both Host and Device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.
- The Direct RAM Access area start at address offset 0x5C000.

## 15.5 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	USB_CTRL	RW	System Control Register
0x004	USB_STATUS	R	System Status Register
0x008	USB_IF	R	Interrupt Flag Register
0x00C	USB_IFS	W1	Interrupt Flag Set Register
0x010	USB_IFC	(R)W1	Interrupt Flag Clear Register
0x014	USB_IEN	RW	Interrupt Enable Register
0x018	USB_ROUTE	RW	I/O Routing Register
0x3C000	USB_GOTGCTL	RWH	OTG Control and Status Register
0x3C004	USB_GOTGINT	RW1H	OTG Interrupt Register
0x3C008	USB_GAHBCFG	RW	AHB Configuration Register

Bit	Name	Reset	Access	Description
11	DEVHNPEN	0	RW	Device HNP Enabled device only
	The application sets host.	this bit when it	successfully	receives a SetFeature.SetHNPEnable command from the connected USB
10	HSTSETHNPEN	0	RW	Host Set HNP Enable host only
	The application sets connected device.	this bit when it	has success	sfully enabled HNP (using the SetFeature.SetHNPEnable command) on the
9	HNPREQ	0	RW	HNP Request device only
	writing a 0 when the	Host Negotiation	on Success S	request to the connected USB host. The application can clear this bit by Status Change bit in the OTG Interrupt register (USB_GOTGINT.HSTNEG-when the HSTNEGSUCSTSCHNG bit is cleared.
8	HSTNEGSCS	0	R	Host Negotiation Success device only
	The core sets this bi this register is set.	t when host neç	gotiation is s	uccessful. The core clears this bit when the HNP Request (HNPREQ) bit in
7	AVALIDOVVAL	0	RW	Avalid Override Value
	This bit is used to se	et Override valu	e for Avalid	signal when USB_GOTGCTL.AVALIDOVEN is set.
6	AVALIDOVEN	0	RW	AValid Override Enable
				o override the Avalid signal using the USB_GOTGCTL.AVALIDOVVAL. idden with USB_GOTGCTL.AVALIDOVVAL.
5	BVALIDOVVAL	0	RW	Bvalid Override Value
	This bit is used to se	t Override valu	e for Bvalid	signal when USB_GOTGCTL.BVALIDOVEN is set.
4	BVALIDOVEN	0	RW	BValid Override Enable
				o override the Bvalid signal using the USB_GOTGCTL.BVALIDOVVAL. idden with USB_GOTGCTL.BVALIDOVVAL.
3	VBVALIDOVVAL	0	RW	VBUS Valid Override Value
	This bit is used to se	t Override valu	e for vbusva	lid signal when USB_GOTGCTL.VBVALIDOVEN is set.
2	VBVALIDOVEN	0	RW	VBUS-Valid Override Enable
				o override the vbusvalid signal using the USB_GOTGCTL.VBVALIDOVVAL. verridden with USB_GOTGCTL.VBVALIDOVVAL.
1	SESREQ	0	RW	Session Request device only
	the Host Negotiation is set. The core clea	Success Staturs this bit when after the B-Se	is Change bi the HSTNE ssion Valid b	request on the USB. The application can clear this bit by writing a 0 when t in the OTG Interrupt register (USB_GOTGINT.HSTNEGSUCSTSCHNG) GSUCSTSCHNG bit is cleared. The application must wait until the VBUS bit in this register (USB_GOTGCTL.BSESVLD) is cleared. This discharge
0	SESREQSCS	0	R	Session Request Success device only
	The core sets this bi	t when a session	on request in	itiation is successful.

## 15.6.9 USB\_GOTGINT - OTG Interrupt Register

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

### 15.6.10 USB\_GAHBCFG - AHB Configuration Register

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

Offset														Bi	t Po	siti	on

22	NOTIALLDMAWRIT	0	RW	Notify All DMA Writes

This bit is programmed to enable the System DMA Done functionality for all the DMA write Transactions corresponding to the Channel/Endpoint. This bit is valid only when USB\_GAHBCFG.REMMEMSUPP is set to 1. When set, the core asserts int\_dma\_req for all the DMA write transactions on the AHB interface along with int\_dma\_done, chep\_last\_transact and chep\_number signal informations. The core waits for sys\_dma\_done signal for all the DMA write transactions in order to complete the transfer of a particular Channel/Endpoint. When cleared, the core asserts int\_dma\_req signal only for the last transaction of DMA write transfer corresponding to a particular Channel/Endpoint. Similarly, the core waits for sys\_dma\_done signal only for that transaction of DMA write to complete the transfer of a particular Channel/Endpoint.

### 21 REMMEMSUPP 0 RW Remote Memory Support

This bit is programmed to enable the functionality to wait for the system DMA Done Signal for the DMA Write Transfers. When set, the int\_dma\_req output signal is asserted when HSOTG DMA starts write transfer to the external memory. When the core is done with the Transfers it asserts int\_dma\_done signal to flag the completion of DMA writes from HSOTG. The core then waits for sys\_dma\_done signal from the system to proceed further and complete the Data Transfer corresponding to a particular Channel/Endpoint. When cleared, the int\_dma\_req and int\_dma\_done signals are not asserted and the core proceeds with the assertion of the XferComp interrupt as soon as the DMA write transfer is done at the HSOTG Core Boundary and it doesn't wait for the sys\_dma\_done signal to complete the DATA.

20:9	Reserved	To ensure tions.	compatibility	with future devices, always write bits to 0. More information in 2.1 Conven-
8	PTXFEMPLVL	0	RW	Periodic TxFIFO Empty Level host only

Indicates when the Periodic TxFIFO Empty Interrupt bit in the Core Interrupt register (USB\_GINTSTS.PTXFEMP) is triggered. This bit is used only in Slave mode.

Value	Mode	Description

Bit	Name	Reset	Access	Description						
31	AHBIDLE	1	R	AHB Master Idle host and device						
	Indicates that the AHI	B Master State I	Machine is	in the IDLE condition.						
30	DMAREQ	0	R	DMA Request Signal host and device						
	Indicates that the DM	A request is in p	rogress. U	sed for debug.						
29:11	Reserved	To ensure compatibility with future devices, always write bits to 0. More information in 2.1 Convertions.								
10:6	TXFNUM	0x00	RW	TxFIFO Number host and device						

This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit.

Value	Mode		Description
0	F0		Host mode: Non-periodic TxFIFO flush.
			Device: Tx FIFO 0 flush
1	F1		Host mode: Periodic TxFIFO flush.
			Device: TXFIFO 1 flush.
2	F2		Device mode: TXFIFO 2 flush.
3	F3		Device mode: TXFIFO 3 flush.
4	F4		Device mode: TXFIFO 4 flush.
5	F5		Device mode: TXFIFO 5 flush.
6	F6		Device mode: TXFIFO 6 flush.
16	FALL		Flush all the transmit FIFOs in device or host mode.
TXFFLSH	0	RW1H	TxFIFO Flush host and device

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. NAK Effective Interrupt ensures the core is not reading from the FIFO. USB\_GRSTCTL.AHBIDLE ensures the core is not writing anything to the FIFO. Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear.

## 15.6.13 USB\_GINTSTS - Interrupt Register

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode. To clear the interrupt status bits of type RW1H, the application must write 1 into the bit.

The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the USB\_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

Bit	Name Reset Access Description
31	WKUPINT 0 RW1H Resume/Remote Wakeup Detected Interrupt host and device
	Wakeup Interrupt during Suspend state. In Device mode this interrupt is asserted only when Host Initiated Resume is detected on USB. In Host mode this interrupt is asserted only when Device Initiated Remote Wakeup is detected on USB. This bit can be set only by the core and the application should write 1 to clear.
30	SESSREQINT 0 RW1H Session Request/New Session Detected Interrupt host and device
	In Host mode, this interrupt is asserted when a session request is detected from the device. In Device mode, this interrupt is asserted when the VBUS voltage reaches the session-valid level. This bit can be set only by the core and the application should write 1 to clear.
29	DISCONNINT 0 RW1H Disconnect Detected Interrupt host only
	Asserted when a device disconnect is detected. This bit can be set only by the core and the application should write 1 to clear it.
28	CONIDSTSCHNG 1 RW1H Connector ID Status Change host and device
	The core sets this bit when there is a change in connector ID status. This bit can be set only by the core and the application should write 1 to clear it.
27	Reserved To ensure compatibility with future devices, always write bits to 0. More information in 2.1 Conventions.
26	PTXFEMP 1 R Periodic TxFIFO Empty host only
	This interrupt is asserted when the Periodic Transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the Periodic Request Queue. The half or completely empty status is determined by the Periodic TxFIFO Empty Level bit in the Core AHB Configuration register (USB_GAHBCFG.PTXFEMPLVL).
25	HCHINT 0 R Host Channels Interrupt host only
	The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in Host mode). The application must read the Host All Channels Interrupt (USB_HAINT) register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding Host Channel-x Interrupt (USB_HCx_INT) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the USB_HCx_INT register to clear this bit.
24	PRTINT 0 R Host Port Interrupt host only
	The core sets this bit to indicate a change in port status in Host mode. The application must read the Host Port Control and Status (USB_HPRT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the Host Port Control and Status register to clear this bit.
23	RESETDET 0 RW1H Reset detected Interrupt device only

In Device mode, this interrupt is asserted when a reset is detected on the USB in EM2 when the device is in Suspend.

In Host mode, this interrupt is not asserted.

## 15.6.14 USB\_GINTMSK - Interrupt Mask Register

This register works with the Interrupt Register (USB\_GINTSTS) to interrupt the application. When an interrupt bit is masked (bit is 0), the interrupt associated with that bit is not generated. However, the USB\_GINTSTS register bit corresponding to that interrupt is still set.

Offset															Ві	it Po	siti	on

## 15.6.15 USB\_GRXSTSR - Receive Status Debug Read Register

A read to the Receive Status Debug Read register returns the contents of the top of the Receive FIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x00000000. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (USB\_GINTSTS.RXFLVL) is asserted.

## 15.6.16 USB\_GRXSTSP - Receive Status Read and Pop Register

A read to the Receive Status Read and Pop register returns the contents of the top of the Receive FIFO and pops the top data entry out of the RxFIFO. The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x00000000. The application must only pop the Receive Status FIFO when the Receive FIFO Non-Empty bit of the Core Interrupt register (USB\_GINTSTS.RXFLVL) is asserted.

 0x17D7
 RW
 Frame Interval

The value that the application programs to this field specifies the interval between two consecutive SOFs (FS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the Port Enable bit of the Host Port Control and Status register (USB\_HPRT.PRTENA) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY Clock Select field of the Host Configuration register (USB\_HCFG.FSLSPCLKSEL). Do not change the value of this field after the initial configuration. Set to 48000 (1 ms at 48 MHz) for FS and 6000 (1 ms at 6 MHz) for LS.

## 15.6.30 USB\_HFNUM - Host Frame Number/Frame Time Remaining Register

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

Offset															Bi	t Po	siti	on

15:0	PTXFSPCAVAIL	0x0200	R	Periodic Transmit Data FIFO Space Available

Indicates the number of free locations available to be written to in the Periodic TxFIFO. Values are in terms of 32-bit words.

# 15.6.32 USB\_HAINT - Host All Channels Interrupt Register

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (USB\_GINTSTS.HCHINT). There is one interrupt bit per channel. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel x Interrupt register.

Offset															Bi	t Po	siti	on

### 15.6.34 USB\_HPRT - Host Port Control and Status Register

This register is available only in Host mode. This register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for the port. Some bits in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (USB\_GINTSTS.PRTINT). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For the RW1H bits, the application must write a 1 to the bit to clear the interrupt.

### 15.6.36 USB\_HCx\_INT - Host Channel x Interrupt Register

This register indicates the status of a channel with respect to USB- and AHB-related events. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (USB\_GINTSTS.HCHINT) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (USB\_HAINT) register to get the exact channel number for the Host Channel x Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USB\_HAINT and USB\_GINTSTS registers.

### 15.6.38 USB\_HCx\_TSIZ - Host Channel x Transfer Size Register

Offset	Bit Position																											
0x3C510	31	30 20 20 20 20 20 20 20 20 20 20 20 20 20								18	17	16	15	4	13	12	7	10	6	8	7	9	5	4	က	2	_	0
Reset		2	00000								00000x0																	
Access		2	2										R≪ ≪															
Name		Old.	PKTCNT F																XFERSIZE									

Bit	Name	Reset	Access	Description
31	Reserved	To ensure co	ompatibility	with future devices, always write bits to 0. More information in 2.1 Conven-
30.29	PID	0x0	RW	Packet ID

The application programs this field with the packet ID type to use for the initial transaction. The host maintains this field for the rest of the transfer.

	Value	Mode		Description							
	0	DATA0		DATA0 PID.							
	1	DATA2		DATA2 PID.							
	2	DATA1		DATA1 PID.							
	3	MDATA		MDATA (non-control) / SETUP (control) PID.							
28:19	PKTCNT	0x000	RW	Packet Count							

This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

18:0 XFERSIZE 0x00000 RW **Transfer Size** 

For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

## 15.6.39 USB\_HCx\_DMAADDR - Host Channel x DMA Address Register

This register is used by the OTG host in the internal DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned.

Offset		Bit Position																														
0x3C514	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	41	13	12	7	10	6	8	7	9	5	4	က	2	_	0
Reset		XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX																														
Access																																
Name		DMAADDR																														
Bit	Na	me					Re	set			Acc	cess	. D	esc	crip	tion																

Bit	Name	Reset	Access	Description
31:0	DMAADDR	0xXXXXXXX X	RW	DMA Address

This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction. The data for this register field is stored in RAM. Thus, the reset value is undefined (X).

#### 15.6.40 USB\_DCFG - Device Configuration Register

This register configures the core in Device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

Offset		Bit Position
0x3C800	30 30 29 28 27 27 26	25 27 27 27 28 28 29 20 21 27 20 20 20 20 20 20 20 20 20 20 20 20 20
Reset	0×02	0000 0000
Access	RW	X         X         X           X         X         X
Name	RESVALID	PERFRINT DEVADDR RNA3ZKHZSUSP NZSTSOUTHSHK DEVSPD

Bit	Name	Reset	Access	Description							
31:26	RESVALID	0x02	RW	Resume Validation Period							
	This field is effective only when USB_DCFG.ENA32KHZSUSP is set. It will control the resume period when the core re-										

sumes from suspend. The core counts for RESVALID number of clock cycles to detect a valid resume when USB DCFG.ENA32KHZSUSP is set.

25:13	Reserved	To ensure tions.	compatibility	with future devices, always write bits to 0. More information in 2.1 Conven-
12:11	PERERINIT	ΛvΛ	RW	Periodic Frame Interval

Indicates the time within a frame at which the application must be notified using the End Of Periodic Frame Interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.

	Value	Mode		Description
	0	80PCNT		80% of the frame interval.
	1	85PCNT		85% of the frame interval.
	2	90PCNT		90% of the frame interval.
	3	95PCNT		95% of the frame interval.
10:4	DEVADDR	0x00	RW	Device Address
	The application mu	st program this	field after e	very SetAddress control command.

**ENA32KHZSUSP** RW **Enable 32 KHz Suspend mode** 

When this bit is set, the core expects that the PHY clock during Suspend is switched from 48 MHz to 32 KHz.

2 NZSTSOUTHSHK Non-Zero-Length Status OUT Handshake

> The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer's Status stage. When set to 1 send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application. When set to 0 send the received OUT packet to the application (zerolength or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the Device Endpoint Control register.

1:0 **DEVSPD** 0x0 RW **Device Speed** 

> Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.

Bit	Name	Reset	Access	Description
	Value	Mode		Description
	2	LS		Low speed (PHY clock is 6 MHz). If you select 6 MHz LS mode, you must do a soft reset.
	3	FS		Full speed (PHY clock is 48 MHz).

### 15.6.45 USB\_DAINT - Device All Endpoints Interrupt Register

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (USB\_GINTSTS.OEPINT or USB\_GINTSTS.IEPINT, respectively). There is one interrupt bit per endpoint. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint Interrupt register (USB\_DIEP0INT/USB\_DIEPx\_INT, USB\_DOEP0INT/USB\_DOEPx\_INT).

## 15.6.51 USB\_DIEP0INT - Device IN Endpoint 0 Interrupt Register

This register indicates the status of endpoint 0 with respect to USB- and AHB-related events. The application must read this register when the IN Endpoints Interrupt bit of the Core Interrupt register (USB\_GINTSTS.IEPINT) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (USB\_DAINT) register to get the exact endpoint number for the Device Endpoint Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USB\_DAINT and USB\_GINTSTS registers.

	This field indicates	that the programr	med transfe	er is complete on the AHB as well as on the USB, for this endpoint.

## 15.6.52 USB\_DIEP0TSIZ - Device IN Endpoint 0 Transfer Size Register

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control register (USB\_DIEPOCTL.EPENA), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit. Nonzero endpoints use the registers for endpoints 1-6.

Bit	Name	Reset	Access	Description
31:0	DIEP0DMAADDR	0xXXXXXXX X	RW	DMA Address

Holds the start address of the external memory for fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received back-to-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. The data for this register field is stored in RAM. Thus, the reset value is undefined (X).

### 15.6.54 USB\_DIEPOTXFSTS - Device IN Endpoint 0 Transmit FIFO Status Register

Bit	Name	Reset	Access	Description
31:0	DMAADDR	0xXXXXXXX X	RW	DMA Address

Holds the start address of the external memory for fetching endpoint data. For control endpoints, this field stores control OUT data packets as well as SETUP transaction data packets. When more than three SETUP packets are received backto-back, the SETUP data packet in the memory is overwritten. This register is incremented on every AHB transaction. The application can give only a DWORD-aligned address. The data for this register field is stored in RAM. Thus, the reset value is undefined (X).

## 15.6.59 USB\_DIEPx\_TXFSTS - Device IN Endpoint x+1 Transmit FIFO Status Register

This read-only register contains the free space information for the Device IN endpoint TxFIFO.

## 15.6.61 USB\_DOEP0INT - Device OUT Endpoint 0 Interrupt Register

This register indicates the status of endpoint 0 with respect to USB- and AHB-related events. The application must read this register when the OUT Endpoints Interrupt bit of the Core Interrupt register (USB\_GINTSTS.OEPINT) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (USB\_DAINT) register to get the exact endpoint number for the Device Endpoint Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the USB\_DAINT and USB\_GINTSTS registers.

Bit	Na	me					Re	set			Ac	ces	s I	Des	crip	tion																
31	EP	ENA	Α				0				RV	V1H		End	poi	nt E	nab	le														

In DMA mode this bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears this bit before setting any of the following interrupts on this endpoint: SETUP Phase Done, Endpoint Disabled, Transfer Completed. For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in mem-

30 EPDIS 0 RW1H Endpoint Disable

ory.

The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint.

29 SETD1PIDOF 0 W1 Set DATA1 PID / Odd Frame

For bulk and interrupt endpoints writing this field sets the Endpoint Data PID / Even or Odd Frame (DPIDEOF) field in this register to DATA1ODD. For isochronous endpoints writing this field sets the Endpoint Data PID / Even or Odd Frame (DPIDEOF) field to odd (DATA1ODD).

28 SETD0PIDEF 0 W1 Set DATA0 PID / Even Frame

For bulk and interrupt endpoints writing this field sets the Endpoint Data PID / Even or Odd Frame (DPIDEOF) field in this register to DATA0EVEN. For isochronous endpoints writing this field sets the Endpoint Data PID / Even or Odd Frame (DPIDEOF) field to odd (DATA0EVEN).

27 SNAK 0 W1 **Set NAK** 

A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint.

26 CNAK 0 W1 Clear NAK

A write to this bit clears the NAK bit for the endpoint.

25:22 Reserved To ensure compatibility with future devices, always write bits to 0. More information in 2.1 Conventions.

21 STALL 0 RW1H STALL Handshake

For non-control, non-isochronous endpoints: The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.

For control endpoints: The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

# 16. I<sup>2</sup>C - Inter-Integrated Circuit Interface

#### **Quick Facts**

#### What?

The I<sup>2</sup>C interface allows communication on I<sup>2</sup>C-buses with the lowest energy consumption possible.

#### Why?

I<sup>2</sup>C is a popular serial bus that enables communication with a number of external devices using only two I/O pins.

#### How?

With the help of DMA, the  $I^2C$  interface allows  $I^2C$  communication with minimal CPU intervention. Address recognition is available in all energy modes (except EM4), allowing the MCU to wait for data on the  $I^2C$ -bus with sub- $\mu$ A current consumption.

#### 16.1 Introduction

The I<sup>2</sup>C module provides an interface between the MCU and a serial I<sup>2</sup>C-bus. It is capable of acting as both master and slave, and supports multi-master buses. Standard-mode, fast-mode and fast-mode plus speeds are supported, allowing transmission rates all the way from 10 kbit/s up to 1 Mbit/s. Slave arbitration and timeouts are also provided to allow implementation of an SMBus compliant system. The interface provided to software by the I<sup>2</sup>C module allows both fine-grained control of the transmission process and close to automatic transfers. Automatic recognition of slave addresses is provided in all energy modes (except EM4).

#### 16.2 Features

- · True multi-master capability
- · Support for different bus speeds
  - · Standard-mode (Sm) bit rate up to 100 kbit/s
  - · Fast-mode (Fm) bit rate up to 400 kbit/s
  - Fast-mode Plus (Fm+) bit rate up to 1 Mbit/s
- · Arbitration for both master and slave (allows SMBus ARP)
- · Clock synchronization and clock stretching
- · Hardware address recognition
  - 7-bit masked address
  - · General call address
  - · Active in all energy modes (except EM4)
- · 10-bit address support
- · Error handling
  - · Clock low timeout
  - · Clock high timeout
  - · Arbitration lost
  - · Bus error detection
- · Double buffered data
- Full DMA support

## 16.3 Functional Description

An overview of the I<sup>2</sup>C module is shown in Figure 16.1 I<sup>2</sup>C Overview on page 537.

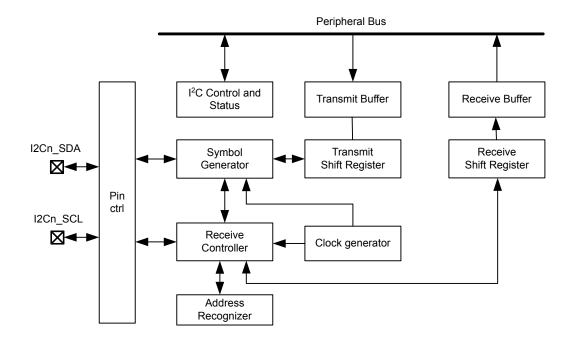

Figure 16.1. I<sup>2</sup>C Overview

#### 16.3.1 I<sup>2</sup>C-Bus Overview

The  $I^2$ C-bus uses two wires for communication; a serial data line (SDA) and a serial clock line (SCL) as shown in the following figure. As a true multi-master bus it includes collision detection and arbitration to resolve situations where multiple masters transmit data at the same time without data loss.

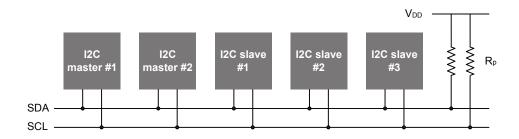

Figure 16.2. I<sup>2</sup>C-Bus Example

Each device on the bus is addressable by a unique address, and an I<sup>2</sup>C master can address all the devices on the bus, including other masters.

Both the bus lines are open-drain. The maximum value of the pull-up resistor can be calculated as a function of the maximal rise-time tr for the given bus speed, and the estimated bus capacitance Cb as shown in the following equation.

$$Rp(max) = \frac{tr}{0.8473} \times Cb$$

The maximal rise times for 100 kHz, 400 kHz, and 1 MHz I2C are 1 µs, 300 ns, and 120 ns respectively.

Note: The GPIO drive strength can be used to control slew rate.

Note: If  $V_{dd}$  drops below the voltage on SCL and SDA lines, the MCU could become back powered and pull the SCL and SDA lines low.

#### 16.3.1.1 START and STOP Conditions

START and STOP conditions are used to initiate and stop transactions on the  $I^2$ C-bus. All transactions on the bus begin with a START condition (S) and end with a STOP condition (P). As shown in the following figure, a START condition is generated by pulling the SDA line low while SCL is high, and a STOP condition is generated by pulling the SDA line high while SCL is high.

Figure 16.3. I<sup>2</sup>C START and STOP Conditions

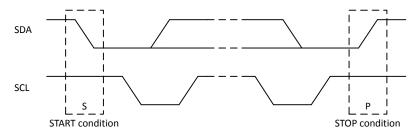

Figure 16.4. I2C START and STOP Conditions

The START and STOP conditions are easily identifiable bus events as they are the only conditions on the bus where a transition is allowed on SDA while SCL is high. During the actual data transmission, SDA is only allowed to change while SCL is low, and must be stable while SCL is high. One bit is transferred per clock pulse on the I2C-bus as shown in the following figure.

Figure 16.5. I<sup>2</sup>C Bit Transfer on I<sup>2</sup>C-Bus

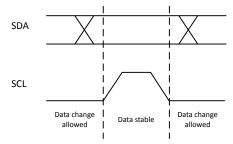

Figure 16.6. I2C Bit Transfer on I2C-Bus

#### 16.3.1.2 Bus Transfer

When a master wants to initiate a transfer on the bus, it waits until the bus is idle and transmits a START condition on the bus. The master then transmits the address of the slave it wishes to interact with and a single R/W bit telling whether it wishes to read from the slave (R/W bit set to 1) or write to the slave (R/W bit set to 0).

After the 7-bit address and the R/W bit, the master releases the bus, allowing the slave to acknowledge the request. During the next bit-period, the slave pulls SDA low (ACK) if it acknowledges the request, or keeps it high if it does not acknowledge it (NACK).

Following the address acknowledge, either the slave or master transmits data, depending on the value of the R/W bit. After every 8 bits (one byte) transmitted on the SDA line, the transmitter releases the line to allow the receiver to transmit an ACK or a NACK. Both the data and the address are transmitted with the most significant bit first.

The number of bytes in a bus transfer is unrestricted. The master ends the transmission after a (N)ACK by sending a STOP condition on the bus. After a STOP condition, any master wishing to initiate a transfer on the bus can try to gain control of it. If the current master wishes to make another transfer immediately after the current, it can start a new transfer directly by transmitting a repeated START condition (Sr) instead of a STOP followed by a START.

Examples of I<sup>2</sup>C transfers are shown in the following figures. The identifiers used are:

- · ADDR Address
- · DATA Data
- · S Start bit
- · Sr Repeated start bit
- P Stop bit
- W/R Read(1)/Write(0)
- A ACK
- N NACK

Figure 16.7. I<sup>2</sup>C Single Byte Write to Slave

Figure 16.8. I<sup>2</sup>C Double Byte Read from Slave

Figure 16.9. I<sup>2</sup>C Single Byte Write, then Repeated Start and Single Byte Read

#### 16.3.1.3 Addresses

 $I^2C$  supports both 7-bit and 10-bit addresses. When using 7-bit addresses, the first byte transmitted after the START-condition contains the address of the slave that the master wants to contact. In the 7-bit address space, several addresses are reserved. These addresses are summarized in Table 16.1  $I^2C$  Reserved  $I^2C$  Addresses on page 541, and include a General Call address which can be used to broadcast a message to all slaves on the  $I^2C$ -bus.

Table 16.1. I<sup>2</sup>C Reserved I<sup>2</sup>C Addresses

I <sup>2</sup> C Address	R/W	Description
0000-000	0	General Call address
0000-000	1	START byte
0000-001	X	Reserved for the C-Bus format
0000-010	X	Reserved for a different bus format
0000-011	X	Reserved for future purposes
0000-1XX	X	Reserved for future purposes
1111-1XX	X	Reserved for future purposes
1111-0XX	X	10 Bit slave addressing mode

### 16.3.1.4 10-Bit Addressing

To address a slave using a 10-bit address, two bytes are required to specify the address instead of one. The seven first bits of the first byte must then be 1111 0XX, where XX are the two most significant bits of the 10-bit address. As with 7-bit addresses, the eight bit of the first byte determines whether the master wishes to read from or write to the slave. The second byte contains the eight least significant bits of the slave address.

When a slave receives a 10-bit address, it must acknowledge both the address bytes if they match the address of the slave.

When performing a master transmitter operation, the master transmits the two address bytes and then the remaining data, as shown in the following figure.

Figure 16.10. I<sup>2</sup>C Master Transmitter/Slave Receiver with 10-Bit Address

When performing a master receiver operation however, the master first transmits the two address bytes in a master transmitter operation, then sends a repeated START followed by the first address byte and then receives data from the addressed slave. The slave addressed by the 10-bit address in the first two address bytes must remember that it was addressed, and respond with data if the address transmitted after the repeated start matches its own address. An example of this (with one byte transmitted) is shown in the following figure.

Figure 16.11. I<sup>2</sup>C Master Receiver/Slave Transmitter with 10-Bit Address

### 16.3.1.5 Arbitration, Clock Synchronization, Clock Stretching

Arbitration and clock synchronization are features aimed at allowing multi-master buses. Arbitration occurs when two devices try to drive the bus at the same time. If one device drives it low, while the other drives it high, the one attempting to drive it high will not be able to do so due to the open-drain bus configuration. Both devices sample the bus, and the one that was unable to drive the bus in the desired direction detects the collision and backs off, letting the other device continue communication on the bus undisturbed.

Clock synchronization is a means of synchronizing the clock outputs from several masters driving the bus at once, and is a requirement for effective arbitration.

Slaves on the bus are allowed to force the clock output on the bus low in order to pause the communication on the bus and give themselves time to process data or perform any real-time tasks they might have. This is called clock stretching.

Arbitration is supported by the I<sup>2</sup>C module for both masters and slaves. Clock synchronization and clock stretching is also supported.

### 16.3.2 Enable and Reset

The  $I^2C$  is enabled by setting the EN bit in the  $I^2C$  is reset, terminating any ongoing transfers.

**Note:** When re-enabling the I<sup>2</sup>C, the ABORT command or the Bus Idle Timeout feature must be applied prior to use even if the BUSY flag is not set.

### 16.3.3 Safely Disabling and Changing Slave Configuration

The I<sup>2</sup>C slave is partially asynchronous, and some precautions are necessary to always ensure a safe slave disable or slave configuration change. These measures should be taken, if (while the slave is enabled) the user cannot guarantee that an address match will not occur at the exact time of slave disable or slave configuration change.

Worst case consequences for an address match while disabling slave or changing configuration is that the slave may end up in an undefined state. To reset the slave back to a known state, the EN bit in I2Cn\_CTRL must be reset. This should be done regardless of whether the slave is going to be re-enabled or not.

#### 16.3.4 Clock Generation

The SCL signal generated by the  $I^2C$  master determines the maximum transmission rate on the bus. The clock is generated as a division of the peripheral clock, and is given by the following equation:

$$f_{SCL} = \frac{1}{T_{low} + T_{high}}$$

where  $T_{low}$  and  $T_{high}$  are the low and high periods of the clock signal respectively, given below. When the clock is not streched, the low and high periods of the clock signal are:

$$T_{\text{high}} = \frac{N_{\text{high}} \times (\text{CLKDIV} + 1)}{f_{\text{HFPERCLK}}}$$

$$T_{\text{low}} = \frac{N_{\text{low}} \times (\text{CLKDIV} + 1)}{f_{\text{HFPERCLK}}}$$

These equations do not apply for low clock division factors (0, 1 and 2) because of synchronization. For these clock division factors, the formulas for computing high and low periods of the clock signal are given in the following table.

Table 16.2. I<sup>2</sup>C High and Low Periods for Low CLKDIV

CLKDIV	Standard (4:4)		Asymmetric (6:3)		Fast (11:6)	
	T <sub>low</sub>	T <sub>high</sub>	T <sub>low</sub>	T <sub>high</sub>	T <sub>low</sub>	T <sub>high</sub>
0	7/f <sub>HFPERCLK</sub>	7/f <sub>HFPERCLK</sub>	9/f <sub>HFPERCLK</sub>	6/f <sub>HFPERCLK</sub>	14/f <sub>HFPERCLK</sub>	9/f <sub>HFPERCLK</sub>
1	10/f <sub>HFPERCLK</sub>	10/f <sub>HFPERCLK</sub>	14/f <sub>HFPERCLK</sub>	8/f <sub>HFPERCLK</sub>	24/f <sub>HFPERCLK</sub>	14/f <sub>HFPERCLK</sub>
2	15/f <sub>HFPERCLK</sub>	15/f <sub>HFPERCLK</sub>	21/f <sub>HFPERCLK</sub>	12/f <sub>HFPERCLK</sub>	36/f <sub>HFPERCLK</sub>	21/f <sub>HFPERCLK</sub>

The values of  $N_{low}$  and  $N_{high}$  and thus the ratio between the high and low parts of the clock signal is controlled by CLHR in the I2Cn\_CTRL register. The available modes are summarized in the following table along with the highest I<sup>2</sup>C-bus frequencies in the given modes that can be achieved without violating the timing specifications of the I<sup>2</sup>C-bus. The frequencies are calculated taking the maximum allowed rise and fall times of SDA and SCL into account. Higher frequencies may be achieved in practice. The 3 extra cycles are synchronization, and must be taken into consideration when DIV in the I2Cn\_CLKDIV register has a low value. The maximum data hold time is dependent on the DIV and is given by:

$$t_{\rm HD,DAT\text{-}max} = \frac{4 + {\rm DIV}}{f_{\rm HFPERCLK}}$$

Note: DIV must be set to 1 during slave mode operation.

Table 16.3. I<sup>2</sup>C Clock Mode

HFPERCLK frequency (MHz)	Clock Low High Ratio (CLHR)	Sm max frequency (kHz)	Fm max frequency (kHz)	Fm+ max frequency (kHz)
48	0	92	400	1000
	1	74	400	959
	2	68	400	799
28	0	92	400	1000
	1	81	400	848
	2	71	400	736

HFPERCLK frequency (MHz)	Clock Low High Ratio (CLHR)	Sm max frequency (kHz)	Fm max frequency (kHz)	Fm+ max frequency (kHz)
21	0	90	400	1000
	1	80	400	954
	2	72	368	552
14	0	92	400	1000
	1	81	400	636
	2	68	368	608
11	0	91	400	785
	1	81	333	733
	2	71	289	478
6.6	0	91	400	471
	1	81	299	439
	2	64	286	286
1.2	0	59	85	85
	1	54	79	79
	2	52	52	52

### 16.3.5 Arbitration

Arbitration is enabled by default, but can be disabled by setting the ARBDIS bit in I2Cn\_CTRL. When arbitration is enabled, the value on SDA is sensed every time the  $I^2C$  module attempts to change its value. If the sensed value is different than the value the  $I^2C$  module tried to output, it is interpreted as a simultaneous transmission by another device, and that the  $I^2C$  module has lost arbitration.

Whenever arbitration is lost, the ARBLOST interrupt flag in  $I2Cn\_IF$  is set, any lines held are released, and the  $I^2C$  device goes idle. If an  $I^2C$  master loses arbitration during the transmission of an address, another master may be trying to address it. The master therefore receives the rest of the address, and if the address matches the slave address of the master, the master goes into either slave transmitter or slave receiver mode.

**Note:** Arbitration can be lost both when operating as a master and when operating as a slave.

#### 16.3.6 Buffers

#### 16.3.6.1 Transmit Buffer and Shift Register

The I<sup>2</sup>C transmitter is double buffered through the transmit buffer and transmit shift register as shown in Figure 16.1 I<sup>2</sup>C Overview on page 537. A byte is loaded into the transmit buffer by writing to I2Cn\_TXDATA. When the transmit shift register is empty and ready for new data, the byte from the transmit buffer is then loaded into the shift register. The byte is then kept in the shift register until it is transmitted. When a byte has been transmitted, a new byte is loaded into the shift register (if available in the transmit buffer). If the transmit buffer is empty, then the shift register also remains empty. The TXC flag in I2Cn\_STATUS and the TXC interrupt flags in I2Cn\_IF are then set, signaling that the transmit shift register is out of data. TXC is cleared when new data becomes available, but the TXC interrupt flag must be cleared by software.

Whenever a byte is loaded from the transmit buffer to the transmit shift register, the TXBL flag in I2Cn\_STATUS and the TXBL interrupt flag in I2Cn\_IF are set. This indicates that there is room in the buffer for more data. TXBL is cleared automatically when data is written to the buffer.

If a write is attempted to the transmit buffer while it is not empty, the TXOF interrupt flag in I2Cn\_IF is set, indicating the overflow. The data already in the buffer remains preserved, and no new data is written.

The transmit buffer and the transmit shift register can be cleared by setting command bit CLEARTX in I2Cn\_CMD. This will prevent the I<sup>2</sup>C module from transmitting the data in the buffer and the shift register, and will make them available for new data. Any byte currently being transmitted will not be aborted. Transmission of this byte will be completed.

## 16.3.6.2 Receive Buffer and Shift Register

Like the transmitter, the I<sup>2</sup>C receiver is double buffered. The receiver uses the receive buffer and receive shift register as shown in Figure 16.1 I<sup>2</sup>C Overview on page 537. When a byte has been fully received by the receive shift register, it is loaded into the receive buffer if there is room for it. Otherwise, the byte waits in the shift register until space becomes available in the buffer.

When a byte becomes available in the receive buffer, the RXDATAV in I2Cn\_STATUS and RXDATAV interrupt flag in I2Cn\_IF are set. The data can now be fetched from the buffer using I2Cn\_RXDATA. Reading from this register will pull a byte out of the buffer, making room for a new byte and clearing RXDATAV in I2Cn\_STATUS and RXDATAV in I2Cn\_IF in the process.

If a read from the receive buffer is attempted through I2Cn\_RXDATA while the buffer is empty, the RXUF interrupt flag in I2Cn\_IF is set, and the data read from the buffer is undefined.

I2Cn\_RXDATAP can be used to read data from the receive buffer without removing it from the buffer. The RXUF interrupt flag in I2Cn\_IF will never be set as a result of reading from I2Cn\_RXDATAP, but the data read through I2Cn\_RXDATAP when the receive buffer is empty is still undefined.

Once a transaction is complete (STOP sent or received), the receive buffer needs to be flushed (all received data must be picked up) before starting a new transaction.

### 16.3.7 Master Operation

A bus transaction is initiated by transmitting a START condition (S) on the bus. This is done by setting the START bit in I2Cn\_CMD. The command schedules a START condition, and makes the I<sup>2</sup>C module generate a start condition whenever the bus becomes free.

The I<sup>2</sup>C-bus is considered busy whenever another device on the bus transmits a START condition. Until a STOP condition is detected, the bus is owned by the master issuing the START condition. The bus is considered free when a STOP condition is transmitted on the bus. After a STOP is detected, all masters that have data to transmit send a START condition and begin transmitting data. Arbitration ensures that collisions are avoided.

When the START condition has been transmitted, the master must transmit a slave address (ADDR) with an R/W bit on the bus. If this address is available in the transmit buffer, the master transmits it immediately, but if the buffer is empty, the master holds the I<sup>2</sup>C-bus while waiting for software to write the address to the transmit buffer.

After the address has been transmitted, a sequence of bytes can be read from or written to the slave, depending on the value of the R/W bit (bit 0 in the address byte). If the bit was cleared, the master has entered a master transmitter role, where it now transmits data to the slave. If the bit was set, it has entered a master receiver role, where it now should receive data from the slave. In either case, an unlimited number of bytes can be transferred in one direction during the transmission.

At the end of the transmission, the master either transmits a repeated START condition (Sr) if it wishes to continue with another transfer, or transmits a STOP condition (P) if it wishes to release the bus.

### 16.3.7.1 Master State Machine

The master state machine is shown in Figure 16.12 I<sup>2</sup>C Master State Machine on page 546. A master operation starts in the far left of the state machine, and follows the solid lines through the state machine, ending the operation or continuing with a new operation when arriving at the right side of the state machine.

Branches in the path through the state machine are the results of bus events and choices made by software, either directly or indirectly. The dotted lines show where I<sup>2</sup>C-specific interrupt flags are set along the path and the full-drawn circles show places where interaction may be required by software to let the transmission proceed.

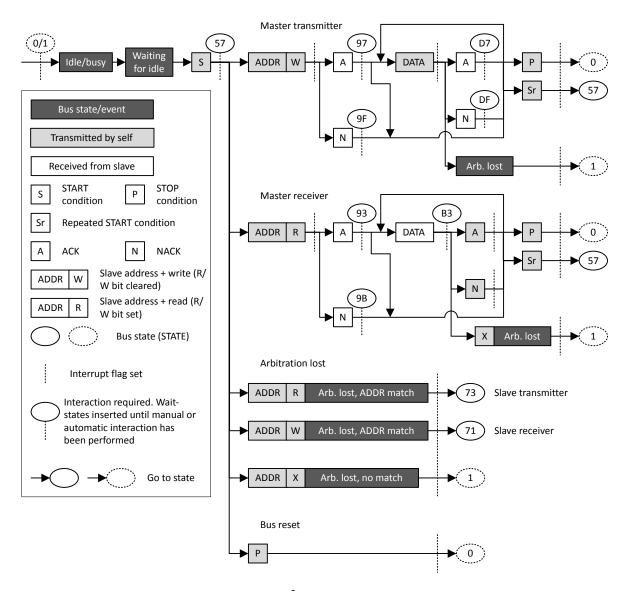

Figure 16.12. I<sup>2</sup>C Master State Machine

#### 16.3.7.2 Interactions

Whenever the  $I^2C$  module is waiting for interaction from software, it holds the bus clock SCL low, freezing all bus activities, and the BUSHOLD interrupt flag in  $I^2C$  module. This state can be read from the  $I^2C$  module. This state can be read from the  $I^2C$  module.

As an example, Table 16.5  $^{12}$ C Master Transmitter on page 549 shows the different states the  $^{12}$ C goes through when operating as a Master Transmitter, i.e. a master that transmits data to a slave. As seen in the table, when a start condition has been transmitted, a requirement is that there is an address and an R/W bit in the transmit buffer. If the transmit buffer is empty, then the BUSHOLD interrupt flag is set, and the bus is held until data becomes available in the buffer. While waiting for the address,  $^{12}$ Cn\_STATE has a value 0x57, which can be used to identify exactly what the  $^{12}$ C module is waiting for.

Note: The bus would never stop at state 0x57 if the address was available in the transmit buffer.

The different interactions used by the  $I^2C$  module are listed in the following table in prioritized order. If a set of different courses of action are possible from a given state, the course of action using the highest priority interactions, that first has everything it is waiting for is the one that is taken.

Table 16.4. I<sup>2</sup>C Interactions in Prioritized Order

Interaction	Priority	Software action	Automatically continues if
STOP*	1	Set the STOP command bit in I2Cn_CMD	PSTOP is set (STOP pending) in I2Cn_STATUS
ABORT	2	Set the ABORT command bit in I2Cn_CMD	Never, the transmission is aborted
CONT*	3	Set the CONT command bit in I2Cn_CMD	PCONT is set in I2Cn_STATUS (CONT pending)
NACK*	4	Set the NACK command bit in I2Cn_CMD	PNACK is set in I2Cn_STATUS (NACK pending)
ACK*	5	Set the ACK command bit in I2Cn_CMD	AUTOACK is set in I2Cn_CTRL or PACK is set in I2Cn_STA-TUS (ACK pending)
ADDR+W -> TXDATA	6	Write an address to the transmit buffer with the R/W bit set	Address is available in transmit buffer with R/W bit set
ADDR+R -> TXDATA	7	Write an address to the transmit buffer with the R/W bit cleared	Address is available in transmit buffer with R/W bit cleared
START*	8	Set the START command bit in I2Cn_CMD	PSTART is set in I2Cn_STA- TUS (START pending)
TXDATA	9	Write data to the transmit buffer	Data is available in transmit buf- fer
RXDATA	10	Read data from receive buffer Space is available in receive buffer	
None	11	No interaction is required	_

The commands marked with a \* in this table can be issued before an interaction is required. When such a command is issued before it can be used/consumed by the I<sup>2</sup>C module, the command is set in a pending state, which can be read from the STATUS register. A pending START command can for instance be identified by PSTART having a high value.

Whenever the  $I^2C$  module requires an interaction, it checks the pending commands. If one or a combination of these can fulfill an interaction, they are consumed by the module and the transmission continues without setting the BUSHOLD interrupt flag in  $I^2Cn_IF$  to get an interaction from software. The pending status of a command goes low when it is consumed.

When several interactions are possible from a set of pending commands, the interaction with the highest priority, i.e. the interaction closest to the top of Table 16.4  $I^2C$  Interactions in Prioritized Order on page 547 is applied to the bus.

Pending commands can be cleared by setting the CLEARPC command bit in I2Cn\_CMD.

#### 16.3.7.2.1 Automatic ACK Interaction

When receiving addresses and data, an ACK command in I2Cn\_CMD is normally required after each received byte. When AUTOACK is set in I2Cn\_CTRL, an ACK is always pending, and the ACK-pending bit PACK in I2Cn\_STATUS is thus always set, even after an ACK has been consumed. This can be used to reduce the amount of software interaction required during a transfer.

### 16.3.7.3 Reset State

After a reset, the state of the  $I^2C$ -bus is unknown. To avoid interrupting transfers on the  $I^2C$ -bus after a reset of the  $I^2C$  module or the entire MCU, the  $I^2C$ -bus is assumed to be busy when coming out of a reset, and the BUSY flag in  $I^2C$ -STATUS is thus set. To be able to carry through master operations on the  $I^2C$ -bus, the bus must be idle.

The bus goes idle when a STOP condition is detected on the bus, but on buses with little activity, the time before the  $I^2C$  module detects that the bus is idle can be significant. There are two ways of assuring that the  $I^2C$  module gets out of the busy state.

- Use the ABORT command in I2Cn\_CMD. When the ABORT command is issued, the I<sup>2</sup>C module is instructed that the bus is idle. The I<sup>2</sup>C module can then initiate master operations.
- Use the Bus Idle Timeout. When SCL has been high for a long period of time, it is very likely that the bus is idle. Set BITO in I2Cn\_CTRL to an appropriate timeout period and set GIBITO in I2Cn\_CTRL. If activity has not been detected on the bus within the timeout period, the bus is then automatically assumed idle, and master operations can be initiated.

Note: If operating in slave mode, the above approach is not necessary.

#### 16.3.7.4 Master Transmitter

To transmit data to a slave, the master must operate as a master transmitter. Table 16.5 I<sup>2</sup>C Master Transmitter on page 549 shows the states the I<sup>2</sup>C module goes through while acting as a master transmitter. Every state where an interaction is required has the possible interactions listed, along with the result of the interactions. The table also shows which interrupt flags are set in the different states. The interrupt flags enclosed in parenthesis may be set. If the BUSHOLD interrupt in I2Cn\_IF is set, the module is waiting for an interaction, and the bus is frozen. The value of I2Cn\_STATE will be equal to the values given in the table when the BUSHOLD interrupt flag is set, and can be used to determine which interaction is required to make the transmission continue.

The interrupt flag START in I2Cn IF is set when the I2C module transmits the START.

A master operation is started by issuing a START command by setting START in I2Cn\_CMD. ADDR +W, i.e. the address of the slave to address + the R/W bit is then required by the  $I^2C$  module. If this is not available in the transmit buffer, then the bus is held and the BUSHOLD interrupt flag is set. The value of I2Cn\_STATE will then be 0x57. As seen in the table, the  $I^2C$  module also stops in this state if the address is not available after a repeated start condition.

To continue, write a byte to I2Cn\_TXDATA with the address of the slave in the 7 most significant bits and the least significant bit cleared (ADDR+W). This address will then be transmitted, and the slave will reply with an ACK or a NACK. If no slave replies to the address, the response will also be NACK. If the address was acknowledged, the master now has four choices. It can send a data byte by placing it in I2Cn\_TXDATA (the master should check the TXBL interrupt flag before writing to I2Cn\_TXDATA), this byte is then transmitted. The master can also stop the transmission by sending a STOP, it can send a repeated start by sending START, or it can send a STOP and then a START as soon as possible.

If a NACK was received, the master has to issue a CONT command in addition to providing data in order to continue transmission. This is not standard I<sup>2</sup>C, but is provided for flexibility. The rest of the options are similar to when an ACK was received.

If a new byte was transmitted, an ACK or NACK is received after the transmission of the byte, and the master has the same options as for when the address was sent.

The master may lose arbitration at any time during transmission. In this case, the ARBLOST interrupt flag in I2Cn\_IF is set. If the arbitration was lost during the transfer of an address, and SLAVE in I2Cn\_CTRL is set, the master then checks which address was transmitted. If it was the address of the master, then the master goes to slave mode.

After a master has transmitted a START and won any arbitration, it owns the bus until it transmits a STOP. After a STOP, the bus is released, and arbitration decides which bus master gains the bus next. The MSTOP interrupt flag in I2Cn\_IF is set when a STOP condition is transmitted by the master.

Table 16.5. I<sup>2</sup>C Master Transmitter

I2Cn_STA	Description	I2Cn_IF	Required interaction	Response
0x57	Start transmitted	START interrupt flag (BUSHOLD interrupt	ADDR +W - > TXDATA	ADDR+W will be sent
		flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
0x57	Repeated start trans- mitted	START interrupt flag (BUSHOLD interrupt	ADDR +W - > TXDATA	ADDR+W will be sent
		flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
_	ADDR+W transmitted	TXBL interrupt flag (TXC interrupt flag)	None	_

I2Cn_STA	Description	I2Cn_IF	Required interaction	Response
0x97	0x97 ADDR+W transmitted, ACK received	,,,	TXDATA	DATA will be sent
		(BUSHOLD interrupt flag)	STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0x9F	ADDR+W DATA will be sent transmit-	NACK (BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be sent
	ted,NACK received		STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
_	Data transmitted	TXBL interrupt flag (TXC interrupt flag)	None	_
0xD7	Data transmitted,ACK		TXDATA	DATA will be sent
	received		STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0xDF	Data transmit- ted,NACK received	NACK(BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be sent
			STOP	STOP will be sent. Bus will be released
			START	Repeated start condition will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
_	Stop transmitted	MSTOP interrupt flag	None	_
			START	START will be sent when bus becomes idle
_	Arbitration lost	ARBLOST interrupt	None	_
		flag	START	START will be sent when bus becomes idle

#### 16.3.7.5 Master Receiver

To receive data from a slave, the master must operate as a master receiver, see Table 16.6 I<sup>2</sup>C Master Receiver on page 551 . This is done by transmitting ADDR+R as the address byte instead of ADDR+W, which is transmitted to become a master transmitter. The address byte loaded into the data register thus has to contain the 7- bit slave address in the 7 most significant bits of the byte, and have the least significant bit set.

When the address has been transmitted, the master receives an ACK or a NACK. If an ACK is received, the ACK interrupt flag in I2Cn\_IF is set, and if space is available in the receive shift register, reception of a byte from the slave begins. If the receive buffer and shift register is full however, the bus is held until data is read from the receive buffer or another interaction is made. Note that the STOP and START interactions have a higher priority than the data-available interaction, so if a STOP or START command is pending, the highest priority interaction will be performed, and data will not be received from the slave.

If a NACK was received, the CONT command in I2Cn\_CMD has to be issued in order to continue receiving data, even if there is space available in the receive buffer and/or shift register.

After a data byte has been received the master must ACK or NACK the received byte. If an ACK is pending or AUTOACK in I2Cn CTRL is set, an ACK is sent automatically and reception continues if space is available in the receive buffer.

If a NACK is sent, the CONT command must be used in order to continue transmission. If an ACK or NACK is issued along with a START or STOP or both, then the ACK/NACK is transmitted and the reception is ended. If START in I2Cn\_CMD is set alone, a repeated start condition is transmitted after the ACK/NACK. If STOP in I2Cn\_CMD is set, a stop condition is sent regardless of whether START is set. If START is set in this case, it is set as pending.

As when operating as a master transmitter, arbitration can be lost as a master receiver. When this happens the ARBLOST interrupt flag in I2Cn\_IF is set, and the master has a possibility of being selected as a slave given the correct conditions.

Table 16.6. I<sup>2</sup>C Master Receiver

I2Cn_STA	Description	I2Cn_IF	Required interaction	Response
0x57	0x57 Start transmitted	START interrupt flag (BUSHOLD interrupt	ADDR +R -> TXDATA	ADDR+R will be sent
		flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
0x57	Repeated START transmitted	START interrupt flag (BUSHOLD interrupt	ADDR +R -> TXDATA	ADDR+R will be sent
		flag)	STOP	STOP will be sent and bus released.
			STOP + START	STOP will be sent and bus released. Then a START will be sent when bus becomes idle.
_	ADDR+R transmitted	TXBL interrupt flag (TXC interrupt flag)	None	_
0x93	ADDR+R transmitted,		RXDATA	Start receiving
	ACK received	flag(BUSHOLD)	STOP	STOP will be sent and the bus released
			START	Repeated START will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle
0x9B	ADDR+R transmit- ted,NACK received	NACK (BUSHOLD)	CONT + RXDATA	Continue, start receiving
			STOP	STOP will be sent and the bus released
			START	Repeated START will be sent
			STOP + START	STOP will be sent and the bus released. Then a START will be sent when the bus becomes idle

I2Cn_STA	Description	I2Cn_IF	Required interaction	Response
0xB3		RXDATA interrupt flag(BUSHOLD inter-	ACK + RXDATA	ACK will be transmitted, reception continues
		rupt flag)	NACK + CONT + RXDATA	NACK will be transmitted, reception continues
			ACK/ NACK + STOP	ACK/NACK will be sent and the bus will be released.
			ACK/ NACK + START	ACK/NACK will be sent, and then a repeated start condition.
			ACK/ NACK + STOP + START	ACK/NACK will be sent and the bus will be released. Then a START will be sent when the bus becomes idle
_	Stop received	MSTOP interrupt flag	None	_
			START	START will be sent when bus becomes idle
_	- Arbitration lost	ARBLOST interrupt	None	_
		flag	START	START will be sent when bus becomes idle

#### 16.3.8 Bus States

The I2Cn\_STATE register can be used to determine which state the  $I^2C$  module and the  $I^2C$  bus are in at a given time. The register consists of the STATE bit-field, which shows which state the  $I^2C$  module is at in any ongoing transmission, and a set of single-bits, which reveal the transmission mode, whether the bus is busy or idle, and whether the bus is held by this  $I^2C$  module waiting for a software response.

The possible values of the STATE field are summarized in Table 16.7 I<sup>2</sup>C STATE Values on page 553. When this field is cleared, the I<sup>2</sup>C module is not a part of any ongoing transmission. The remaining status bits in the I2Cn\_STATE register are listed in Table 16.8 I<sup>2</sup>C Transmission Status on page 553.

Table 16.7. I<sup>2</sup>C STATE Values

Mode	Value	Description	
IDLE	0	No transmission is being performed by this module.	
WAIT	1	Waiting for idle. Will send a start condition as soon as the bus is idle.	
START	2	Start being transmitted	
ADDR	3	Address being transmitted or has been received	
ADDRACK	4	Address ACK/NACK being transmitted or received	
DATA	5	Data being transmitted or received	
DATAACK	6	Data ACK/NACK being transmitted or received	

Table 16.8. I<sup>2</sup>C Transmission Status

MASTER	Set when operating as a master. Cleared at all other times.
Bit	Description
BUSY	Set whenever there is activity on the bus. Whether or not this module is responsible for the activity cannot be determined by this byte.
TRANSMITTER	Set when operating as a transmitter; either a master transmitter or a slave transmitter. Cleared at all other times
BUSHOLD	Set when the bus is held by this I <sup>2</sup> C module because an action is required by software.
NACK	Only valid when bus is held and STATE is ADDRACK or DATAACK. In that case it is set if a NACK was received. In all other cases, the bit is cleared.

**Note:** I2Cn\_STATE reflects the internal state of the  $I^2C$  module, and therefore only held constant as long as the bus is held, i.e. as long as BUSHOLD in I2Cn\_STATUS is set.

## 16.3.9 Slave Operation

The I<sup>2</sup>C module operates in master mode by default. To enable slave operation, i.e. to allow the device to be addressed as an I<sup>2</sup>C slave, the SLAVE bit in I2Cn\_CTRL must be set. In this case the slave operates in a mixed mode, both capable of starting transmissions as a master, and being addressed as a slave. When operating in the slave mode, HFPERCLK frequency must be higher than 4.2 MHz for Standard-mode, 11 MHz for Fast-mode, and 24.4 MHz for Fast-mode Plus.

### 16.3.9.1 Slave State Machine

The slave state machine is shown in the following figure. The dotted lines show where  $I^2C$ -specific interrupt flags are set. The full-drawn circles show places where interaction may be required by software to let the transmission proceed.

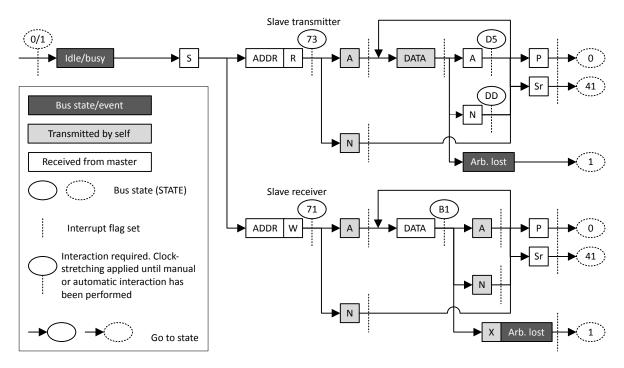

Figure 16.13. I<sup>2</sup>C Slave State Machine

### 16.3.9.2 Address Recognition

The I<sup>2</sup>C module provides automatic address recognition for 7-bit addresses. 10-bit address recognition is not fully automatic, but can be assisted by the 7-bit address comparator as shown in 16.3.11 Using 10-Bit Addresses. Address recognition is supported in all energy modes (except EM4).

The slave address, i.e. the address which the I<sup>2</sup>C module should be addressed with, is defined in the I2Cn\_SADDR register. In addition to the address, a mask must be specified, telling the address comparator which bits of an incoming address to compare with the address defined in I2Cn\_SADDR. The mask is defined in I2Cn\_SADDRMASK, and for every zero in the mask, the corresponding bit in the slave address is treated as a don't-care.

An incoming address that fails address recognition is automatically replied to with a NACK. Since only the bits defined by the mask are checked, a mask with a value 0x00 will result in all addresses being accepted. A mask with a value 0x7F will only match the exact address defined in I2Cn\_SADDR, while a mask 0x70 will match all addresses where the three most significant bits in I2Cn\_SADDR and the incoming address are equal.

If GCAMEN in I2Cn\_CTRL is set, the general call address is always accepted regardless of the result of the address recognition. The start-byte, i.e. the general call address with the R/W bit set is ignored unless it is included in the defined slave address.

When an address is accepted by the address comparator, the decision of whether to ACK or NACK the address is passed to software.

#### 16.3.9.3 Slave Transmitter

When SLAVE in I2Cn\_CTRL is set, the RSTART interrupt flag in I2Cn\_IF will be set when repeated START conditions are detected. After a START or repeated START condition, the bus master will transmit an address along with an R/W bit. If there is no room in the receive shift register for the address, the bus will be held by the slave until room is available in the shift register. Transmission then continues and the address is loaded into the shift register. If this address does not pass address recognition, it is automatically NACK'ed by the slave, and the slave goes to an idle state. The address byte is in this case discarded, making the shift register ready for a new address. It is not loaded into the receive buffer.

If the address was accepted and the R/W bit was set (R), indicating that the master wishes to read from the slave, the slave now goes into the slave transmitter mode. Software interaction is now required to decide whether the slave wants to acknowledge the request or not. The accepted address byte is loaded into the receive buffer like a regular data byte. If no valid interaction is pending, the bus is held until the slave responds with a command. The slave can reject the request with a single NACK command.

The slave will in that case go to an idle state, and wait for the next start condition. To continue the transmission, the slave must make sure data is loaded into the transmit buffer and send an ACK. The loaded data will then be transmitted to the master, and an ACK or NACK will be received from the master.

Data transmission can also continue after a NACK if a CONT command is issued along with the NACK. This is not standard I<sup>2</sup>C however.

If the master responds with an ACK, it may expect another byte of data, and data should be made available in the transmit buffer. If data is not available, the bus is held until data is available.

If the response is a NACK however, this is an indication of that the master has received enough bytes and wishes to end the transmission. The slave now automatically goes idle, unless CONT in I2Cn\_CMD is set and data is available for transmission. The latter is not standard I<sup>2</sup>C.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag in I2Cn\_IF is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag is not set.

**Note:** The SSTOP interrupt flag in I2Cn\_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn\_CTRL is set and a STOP condition is detected

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn\_IF is set, the bus is released and the slave goes idle.

See Table 16.9 I<sup>2</sup>C Slave Transmitter on page 555 for more information.

Table 16.9. I<sup>2</sup>C Slave Transmitter

0x41	Repeated START received	RSTART interrupt flag (BUSHOLD in- terrupt flag)	RXDATA	Receive and compare address
I2Cn_STA	Description	I2Cn_IF	Required in- teraction	Response
0x75	ADDR + R received	ADDR interrupt flag	ACK + TXDATA	ACK will be sent, then DATA
		RXDATA interrupt flag	NACK	NACK will be sent, slave goes idle
		(BUSHOLD interrupt flag)	NACK + CONT + TXDATA	NACK will be sent, then DATA.
_	Data transmitted	TXBL interrupt flag (TXC interrupt flag)	None	_
0xD5	Data transmitted, ACK received	ACK interrupt flag (BUSHOLD interrupt flag)	TXDATA	DATA will be transmitted

0x41	Repeated START re- ceived	RSTART interrupt flag (BUSHOLD in- terrupt flag)	RXDATA	Receive and compare address
0xDD	Data transmitted,	NACK interrupt flag	None	The slave goes idle
	NACK received	(BUSHOLD interrupt flag)	CONT + TXDATA	DATA will be transmitted
_	Stop received	SSTOP interrupt flag	None	The slave goes idle
			START	START will be sent when bus becomes idle
_	Arbitration lost	ARBLOST interrupt	None	The slave goes idle
		flag	START	START will be sent when the bus becomes idle

## 16.3.9.4 Slave Receiver

A slave receiver operation is started in the same way as a slave transmitter operation, with the exception that the address transmitted by the master has the R/W bit cleared (W), indicating that the master wishes to write to the slave. The slave then goes into slave receiver mode.

To receive data from the master, the slave should respond to the address with an ACK and make sure space is available in the receive buffer. Transmission will then continue, and the slave will receive a byte from the master.

If a NACK is sent without a CONT, the transmission is ended for the slave, and it goes idle. If the slave issues both the NACK and CONT commands and has space available in the receive buffer, it will be open for continuing reception from the master.

When a byte has been received from the master, the slave must ACK or NACK the byte. The responses here are the same as for the reception of the address byte.

The master ends the transmission by sending a STOP or a repeated START. The SSTOP interrupt flag is set when the master transmits a STOP condition. If the transmission is ended with a repeated START, then the SSTOP interrupt flag in I2Cn\_IF is not set.

**Note:** The SSTOP interrupt flag in I2Cn\_IF will be set regardless of whether the slave is participating in the transmission or not, as long as SLAVE in I2Cn\_CTRL is set and a STOP condition is detected

If arbitration is lost at any time during transmission, the ARBLOST interrupt flag in I2Cn\_IF is set, the bus is released and the slave goes idle.

See Table 16.10 I<sup>2</sup>C - Slave Receiver on page 557 for more information.

Table 16.10. I<sup>2</sup>C - Slave Receiver

I2Cn_STA	Description	I2Cn_IF	Required interaction	Response
_	Repeated START received	RSTART interrupt flag (BUSHOLD interrupt flag)	RXDATA	Receive and compare address
0x71	ADDR + W received	ADDR interrupt flag RXDATA interrupt flag (BUSHOLD interrupt flag)	ACK + RXDATA	ACK will be sent and data will be received
			NACK	NACK will be sent, slave goes idle
			NACK + CONT + RXDATA	NACK will be sent and DATA will be received.
0xB1	Data received	RXDATA interrupt flag (BUSHOLD interrupt	ACK + RXDATA	ACK will be sent and data will be received
		flag)	NACK	NACK will be sent and slave will go idle
			NACK + CONT + RXDATA	NACK will be sent and data will be received
_	Stop received	SSTOP interrupt flag	None	The slave goes idle
			START	START will be sent when bus becomes idle
_	Arbitration lost	ARBLOST interrupt	None	The slave goes idle
		flag	START	START will be sent when the bus becomes idle

### 16.3.10 Transfer Automation

The I<sup>2</sup>C can be set up to complete transfers with a minimal amount of interaction.

#### 16.3.10.1 DMA

DMA can be used to automatically load data into the transmit buffer and load data out from the receive buffer. When using DMA, software is thus relieved of moving data to and from memory after each transferred byte.

### 16.3.10.2 Automatic ACK

When AUTOACK in I2Cn\_CTRL is set, an ACK is sent automatically whenever an ACK interaction is possible and no higher priority interactions are pending.

#### 16.3.10.3 Automatic STOP

A STOP can be generated automatically on two conditions. These apply only to the master transmitter.

If AUTOSN in I2Cn\_CTRL is set, the I<sup>2</sup>C module ends a transmission by transmitting a STOP condition when operating as a master transmitter and a NACK is received.

If AUTOSE in I2Cn\_CTRL is set, the I<sup>2</sup>C module always ends a transmission when there is no more data in the transmit buffer. If data has been transmitted on the bus, the transmission is ended after the (N)ACK has been received by the slave. If a START is sent when no data is available in the transmit buffer and AUTOSE is set, then the STOP condition is sent immediately following the START. Software must thus make sure data is available in the transmit buffer before the START condition has been fully transmitted if data is to be transferred.

## 16.3.11 Using 10-Bit Addresses

When using 10-bit addresses in slave mode, set the I2Cn\_SADDR register to 1111 0XX where XX are the two most significant bits of the 10-bit address, and set I2Cn\_SADDRMASK to 0xFF. Address matches will now be given on all 10-bit addresses where the two most significant bits are correct.

When receiving an address match, the slave must acknowledge the address and receive the first data byte. This byte contains the second part of the 10-bit address. If it matches the address of the slave, the slave should ACK the byte to continue the transmission, and if it does not match, the slave should NACK it.

When the master is operating as a master transmitter, the data bytes will follow after the second address byte. When the master is operating as a master receiver however, a repeated START condition is sent after the second address byte. The address sent after this repeated START is equal to the first of the address bytes transmitted previously, but now with the R/W byte set, and only the slave that found a match on the entire 10-bit address in the previous message should ACK this address. The repeated start should take the master into a master receiver mode, and after the single address byte sent this time around, the slave begins transmission to the master.

### 16.3.12 Error Handling

### 16.3.12.1 ABORT Command

Some bus errors may require software intervention to be resolved. The I<sup>2</sup>C module provides an ABORT command, which can be set in I2Cn CMD, to help resolve bus errors.

When the bus for some reason is locked up and the  $I^2C$  module is in the middle of a transmission it cannot get out of, or for some other reason the  $I^2C$  wants to abort a transmission, the ABORT command can be used.

Setting the ABORT command will make the I<sup>2</sup>C module discard any data currently being transmitted or received, release the SDA and SCL lines and go to an idle mode. ABORT effectively makes the I<sup>2</sup>C module forget about any ongoing transfers.

### 16.3.12.2 Bus Reset

A bus reset can be performed by setting the START and STOP commands in I2Cn\_CMD while the transmit buffer is empty. A START condition will then be transmitted, immediately followed by a STOP condition. A bus reset can also be performed by transmitting a START command with the transmit buffer empty and AUTOSE set.

#### 16.3.12.3 I<sup>2</sup>C-Bus Errors

An I<sup>2</sup>C-bus error occurs when a START or STOP condition is misplaced, which happens when the value on SDA changes while SCL is high during bit-transmission on the I<sup>2</sup>C-bus. If the I<sup>2</sup>C module is part of the current transmission when a bus error occurs, any data currently being transmitted or received is discarded, SDA and SCL are released, the BUSERR interrupt flag in I<sup>2</sup>Cn\_IF is set to indicate the error, and the module automatically takes a course of action as defined in Table 16.11 I<sup>2</sup>C Bus Error Response on page 559.

## Table 16.11. I<sup>2</sup>C Bus Error Response

	Misplaced START	Misplaced STOP
In a master/slave operation	Treated as START. Receive address.	Go idle. Perform any pending actions.

### 16.3.12.4 Bus Lockup

A lockup occurs when a master or slave on the  $I^2C$ -bus has locked the SDA or SCL at a low value, preventing other devices from putting high values on the bus, and thus making communication on the bus impossible.

Many slave-only devices operating on an I<sup>2</sup>C-bus are not capable of driving SCL low, but in the rare case that SCL is stuck LOW, the advice is to apply a hardware reset signal to the slaves on the bus. If this does not work, cycle the power to the devices in order to make them release SCL.

When SDA is stuck low and SCL is free, a master should send 9 clock pulses on SCL while tristating the SDA. This procedure is performed in the GPIO module after clearing the I2C\_ROUTE register and disabling the I2C module. The device that held the bus low should release it sometime within those 9 clocks. If not, use the same approach as for when SCL is stuck, resetting and possibly cycling power to the slaves.

Lockup of SDA can be detected by keeping count of the number of continuous arbitration losses during address transmission. If arbitration is also lost during the transmission of a general call address, i.e. during the transmission of the STOP condition, which should never happen during normal operation, this is a good indication of SDA lockup.

Detection of SCL lockups can be done using the timeout functionality defined in 16.3.12.6 Clock Low Timeout.

#### 16.3.12.5 Bus Idle Timeout

When SCL has been high for a significant amount of time, this is a good indication of that the bus is idle. On an SMBus system, the bus is only allowed to be in this state for a maximum of 50 µs before the bus is considered idle.

The bus idle timeout BITO in I2Cn\_CTRL can be used to detect situations where the bus goes idle in the middle of a transmission. The timeout can be configured in BITO, and when the bus has been idle for the given amount of time, the BITO interrupt flag in I2Cn\_IF is set. The bus can also be set idle automatically on a bus idle timeout. This is enabled by setting GIBITO in I2Cn\_CTRL.

When the bus idle timer times out, it wraps around and continues counting as long as its condition is true. If the bus is not set idle using GIBITO or the ABORT command in I2Cn CMD, this will result in periodic timeouts.

**Note:** This timeout will be generated even if SDA is held low.

The bus idle timeout is active as long as the bus is busy, i.e. BUSY in I2Cn\_STATUS is set. The timeout can be used to get the  $I^2$ C module out of the busy-state it enters when reset, see 16.3.7.3 Reset State.

### 16.3.12.6 Clock Low Timeout

The clock timeout, which can be configured in CLTO in I2Cn\_CTRL, starts counting whenever SCL goes low, and times out if SCL does not go high within the configured timeout. A clock low timeout results in CLTOIF in I2Cn\_IF being set, allowing software to take action.

When the timer times out, it wraps around and continues counting as long as SCL is low. An SCL lockup will thus result in periodic clock low timeouts as long as SCL is low.

## 16.3.13 DMA Support

The I<sup>2</sup>C module has full DMA support. The DMA controller can write to the transmit buffer using the I2Cn\_TXDATA register, and it can read from the receive buffer using the RXDATA register. A request for the DMA controller to read from the I<sup>2</sup>C receive buffer can come from the following source:

· Data available in the receive buffer

A write request can come from one of the following sources:

- · Transmit buffer and shift register empty. No data to send
- · Transmit buffer empty

### 16.3.14 Interrupts

The interrupts generated by the I<sup>2</sup>C module are combined into one interrupt vector, I2C\_INT. If I<sup>2</sup>C interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in I2Cn\_IF and their corresponding bits in I2Cn\_IEN are set.

## 16.3.15 Wake-Up

The I<sup>2</sup>C receive section can be active all the way down to energy mode EM3, and can wake up the CPU on address interrupt. All address match modes are supported.

### 16.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	I2Cn_CTRL	RW	Control Register

	2	FAST		The ratio between low period and high period counters ( $N_{low}$ : $N_{high}$ ) is 11:6
7	Reserved	To ensure contions.	mpatibility	with future devices, always write bits to 0. More information in 2.1 Conven-
6	GCAMEN	0	RW	General Call Address Match Enable
	Set to enable address	s match on gene	eral call in a	addition to the programmed slave address.
	Value			Description
	0			General call address will be NACK'ed if it is not included by the slave address and address mask.
	1			When a general call address is received, a software response is required.
5	ARBDIS	0	RW	Arbitration Disable
	A master or slave will	not release the	bus upon	losing arbitration.
	Value			Description
	0			When a device loses arbitration, the ARB interrupt flag is set and the bus is released.

1

When a device loses arbitration, the ARB interrupt flag is set, but communication proceeds.

Bit	Name	Reset	Access	Description
4	AUTOSN	0	RW	Automatic STOP on NACK
	Write to 1 to mak	e a master transm	nitter send a	STOP when a NACK is received from a slave.
	Value			Description
	0			Stop is not automatically sent if a NACK is received from a slave.
	1			The master automatically sends a STOP if a NACK is received from a slave.
3	AUTOSE	0	RW	Automatic STOP when Empty
	Write to 1 to mak	e a master transm	nitter send a	STOP when no more data is available for transmission.
	Value			Description
	0			A stop must be sent manually when no more data is to be transmitted.
	1			The master automatically sends a STOP when no more data is available for transmission.
2	AUTOACK	0	RW	Automatic Acknowledge
	Set to enable aut	omatic acknowled	ges.	
	Value			Description
	0			Software must give one ACK command for each ACK transmitted on the I <sup>2</sup> C bus.
	1			Addresses that are not automatically NACK'ed, and all data is automatically acknowledged.
1	SLAVE	0	RW	Addressable as Slave
	Set this bit to allo	w the device to be	selected as	an I <sup>2</sup> C slave.
	Value			Description
	0			All addresses will be responded to with a NACK
	1			Addresses matching the programmed slave address or the general call address (if enabled) require a response from software. Other addresses are automatically responded to with a NACK.
)	EN	0	RW	I <sup>2</sup> C Enable
	Use this bit to en	able or disable the	e I <sup>2</sup> C module.	
	Value			Description
	0			The I <sup>2</sup> C module is disabled. And its internal state is cleared
	1			The I <sup>2</sup> C module is enabled.

# 17. USART - Universal Synchronous Asynchronous Receiver/Transmitter

#### **Quick Facts**

#### What?

The USART handles high-speed UART, SPIbus, SmartCards, and IrDA communication.

### Why?

Serial communication is frequently used in embedded systems and the USART allows efficient communication with a wide range of external devices.

#### How?

The USART has a wide selection of operating modes, frame formats and baud rates. The multiprocessor mode allows the USART to remain idle when not addressed. Triple buffering and DMA support makes high datarates possible with minimal CPU intervention and it is possible to transmit and receive large frames while the MCU remains in EM1.

### 17.1 Introduction

The Universal Synchronous Asynchronous serial Receiver and Transmitter (USART) is a very flexible serial I/O module. It supports full duplex asynchronous UART communication as well as RS-485, SPI, MicroWire and 3-wire. It can also interface with ISO7816 Smart-Cards, and IrDA devices.

#### 17.2 Features

- · Asynchronous and synchronous (SPI) communication
- · Full duplex and half duplex
- Separate TX/RX enable
- Separate receive / transmit 2-level buffers, with additional separate shift registers
- Programmable baud rate, generated as an fractional division from the peripheral clock (HFPERCLK<sub>USARTn</sub>)
- · Max bit-rate
  - SPI master mode, peripheral clock rate/2
  - SPI slave mode, peripheral clock rate/8
  - UART mode, peripheral clock rate/16, 8, 6, or 4
- · Asynchronous mode supports
  - · Majority vote baud-reception
  - · False start-bit detection
  - · Break generation/detection
  - · Multi-processor mode
- · Synchronous mode supports
  - · All 4 SPI clock polarity/phase configurations
  - · Master and slave mode
- · Data can be transmitted LSB first or MSB first
- Configurable number of data bits, 4-16 (plus the parity bit, if enabled)
  - · HW parity bit generation and check
- Configurable number of stop bits in asynchronous mode: 0.5, 1, 1.5, 2
- · HW collision detection
- · Multi-processor mode
- · IrDA modulator on USART0
- · SmartCard (ISO7816) mode
- · I2S mode
- · Separate interrupt vectors for receive and transmit interrupts
- · Loopback mode
  - · Half duplex communication
  - · Communication debugging
- · PRS RX input

## 17.3 Functional Description

An overview of the USART module is shown in the following figure.

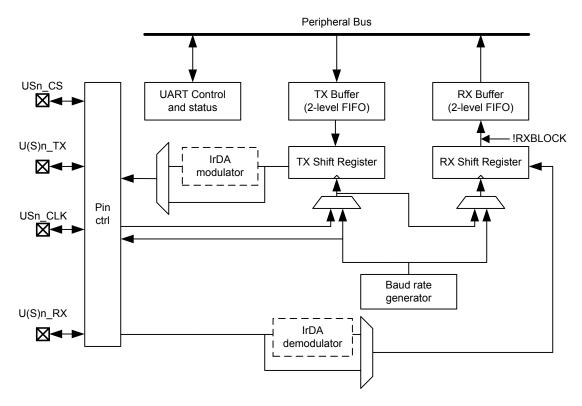

Figure 17.1. USART Overview

### 17.3.1 Modes of Operation

The USART operates in either asynchronous or synchronous mode.

In synchronous mode, a separate clock signal is transmitted with the data. This clock signal is generated by the bus master, and both the master and slave sample and transmit data according to this clock. Both master and slave modes are supported by the USART. The synchronous communication mode is compatible with the Serial Peripheral Interface Bus (SPI) standard.

In asynchronous mode, no separate clock signal is transmitted with the data on the bus. The USART receiver thus has to determine where to sample the data on the bus from the actual data. To make this possible, additional synchronization bits are added to the data when operating in asynchronous mode, resulting in a slight overhead.

Asynchronous or synchronous mode can be selected by configuring SYNC in USARTn\_CTRL. The options are listed with supported protocols in the following. Full duplex and half duplex communication is supported in both asynchronous and synchronous mode.

Table 17.1. USART Asynchronous vs. Synchronous Mode

SYNC	Communication Mode	Supported Protocols
0	Asynchronous	RS-232, RS-485 (w/external driver), IrDA, ISO 7816
1	Synchronous	SPI, MicroWire, 3-wire

The following table explains the functionality of the different USART pins when the USART operates in different modes. Pin functionality enclosed in square brackets is optional, and depends on additional configuration parameters. LOOPBK and MASTER are discussed in 17.3.2.5 Local Loopback and 17.3.3.3 Master Mode respectively.

Table 17.2. USART Pin Usage

SYNC	LOOPBK	MASTER	Pin functionality	Pin functionality						
			U(S)n_TX (MO- SI)	U(S)n_RX (MI- SO)	USn_CLK	USn_CS				
0	0	х	Data out	Data in	_	[Driver enable]				
1	1	х	Data out/in	_	_	[Driver enable]				
1	0	0	Data in	Data out	Clock in	Slave select				
1	0	1	Data out	Data in	Clock out	[Auto slave se- lect]				
1	1	0	Data out/in	_	Clock in	Slave select				
1	1	1	Data out/in	_	Clock out	Auto slave select]				

### 17.3.2 Asynchronous Operation

#### 17.3.2.1 Frame Format

The frame format used in asynchronous mode consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 4 to 16 data bits and an optional parity bit. Finally, a number of stop-bits, where the line is driven high, end the frame. An example frame is shown in the following figure.

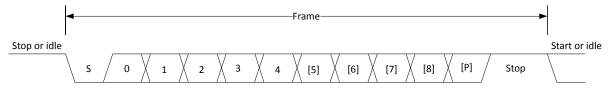

Figure 17.2. USART Asynchronous Frame Format

The number of data bits in a frame is set by DATABITS in USARTn\_FRAME, see Table 17.3 USART Data Bits on page 582, and the number of stop-bits is set by STOPBITS in USARTn\_FRAME, see Table 17.4 USART Stop Bits on page 582. Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY, also in USARTn\_FRAME. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

Table 17.3. USART Data Bits

DATA BITS [3:0]	Number of Data bits
0001	4

Table 17.4. USART Stop Bits

STOP BITS [1:0]	Number of Stop bits
00	0.5
01	1 (Default)
10	1.5
11	2

The order in which the data bits are transmitted and received is defined by MSBF in USARTn\_CTRL. When MSBF is cleared, data in a frame is sent and received with the least significant bit first. When it is set, the most significant bit comes first.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn\_CTRL, and the format expected by the receiver can be inverted by setting RXINV in USARTn\_CTRL. These bits affect the entire frame, not only the data bits. An inverted frame has a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits.

### 17.3.2.1.1 Parity Bit Calculation and Handling

When parity bits are enabled, hardware automatically calculates and inserts any parity bits into outgoing frames, and verifies the received parity bits in incoming frames. This is true for both asynchronous and synchronous modes, even though it is mostly used in asynchronous communication. The possible parity modes are defined in the following table. When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd.

Table 17.5. USART Parity Bits

STOP BITS [1:0]	Description
00	No parity bit (Default)
01	Reserved
10	Even parity
11	Odd parity

#### 17.3.2.2 Clock Generation

The USART clock defines the transmission and reception data rate. When operating in asynchronous mode, the baud rate (bit-rate) is given by the following equation

$$br = \frac{f_{\text{HFPERCLK}}}{\text{oversample} \times (1 + \frac{\text{USARTn\_CLKDIV}}{256})}$$

where  $f_{HFPERCLK}$  is the peripheral clock (HFPERCLK<sub>USARTn</sub>) frequency and oversample is the oversampling rate as defined by OVS in USARTn\_CTRL, see the following table.

Table 17.6. USART Oversampling

OVS [1:0]	Oversample
00	16
01	8
10	6
11	4

The USART has a fractional clock divider to allow the USART clock to be controlled more accurately than what is possible with a standard integral divider.

The clock divider used in the USART is a 15-bit value, with a 13-bit integral part and a 2-bit fractional part. The fractional part is configured in the two LSBs of DIV in USART\_CLKDIV. The lowest achievable baud rate at 32 MHz is about 244 bauds/sec.

Fractional clock division is implemented by distributing the selected fraction over four baud periods. The fractional part of the divider tells how many of these periods should be extended by one peripheral clock cycle.

Given a desired baud rate brdesired, the clock divider USARTn CLKDIV can be calculated by using the following equation:

USARTn\_CLKDIV = 
$$256 \times (\frac{f_{\text{HFPERCLK}}}{\text{oversample} \times \text{brdesired}} - 1)$$

The following table shows a set of desired baud rates and how accurately the USART is able to generate these baud rates when running at a 4 MHz peripheral clock, using 16x or 8x oversampling.

Table 17.7. USART Baud Rates @ 4MHz Peripheral Clock

Desired baud	USARTn_OVS =0	0		USARTn_OVS =01					
rate [baud/s]	USARTn_CLKDIV 256	/Actual baud rate [baud/s]	Error %	USARTn_CLKDIV 256	/Actual baud rate [baud/s]	Error %

#### 17.3.2.3 Data Transmission

Asynchronous data transmission is initiated by writing data to the transmit buffer using one of the methods described in 17.3.2.3.1 Transmit Buffer Operation. When the transmission shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available.

Transmission is enabled through the command register USARTn\_CMD by setting TXEN, and disabled by setting TXDIS in the same command register. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in USARTn\_STATUS.

When the USART transmitter is enabled and there is no data in the transmit shift register or transmit buffer, the TXC flag in USARTn\_STATUS and the TXC interrupt flag in USARTn\_IF are set, signaling that the transmitter is idle. The TXC status flag is cleared when a new frame becomes available for transmission, but the TXC interrupt flag must be cleared by software.

### 17.3.2.3.1 Transmit Buffer Operation

The transmit-buffer is a 2-level FIFO buffer. A frame can be loaded into the buffer by writing to USARTn\_TXDATA, USARTn\_TXDATA, USARTn\_TXDOUBLE or USARTn\_TXDOUBLEX. Using USARTn\_TXDATA allows 8 bits to be written to the buffer, while using USARTn\_TXDOUBLE will write 2 frames of 8 bits to the buffer. If 9-bit frames are used, the 9th bit of the frames will in these cases be set to the value of BIT8DV in USARTn\_CTRL.

To set the 9th bit directly and/or use transmission control, USARTn\_TXDATAX and USARTn\_TXDOUBLEX must be used. USARTn\_TXDATAX allows 9 data bits to be written, as well as a set of control bits regarding the transmission of the written frame. Every frame in the buffer is stored with 9 data bits and additional transmission control bits. USARTn\_TXDOUBLEX allows two frames, complete with control bits to be written at once. When data is written to the transmit buffer using USARTn\_TXDATAX and USARTn\_TXDOUBLEX, the 9th bit(s) written to these registers override the value in BIT8DV in USARTn\_CTRL, and alone define the 9th bits that are transmitted if 9-bit frames are used. The following figure shows the basics of the transmit buffer when DATABITS in USARTn\_FRAME is configured to less than 10 bits.

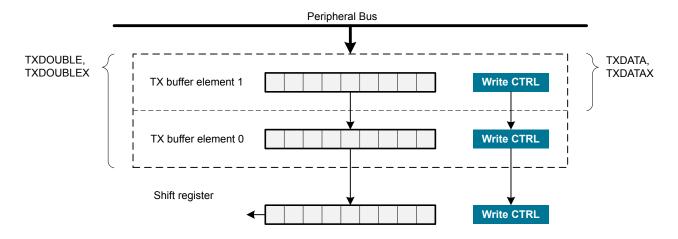

Figure 17.3. USART Transmit Buffer Operation

When writing more frames to the transmit buffer than there is free space for, the TXOF interrupt flag in USARTn\_IF will be set, indicating the overflow. The data already in the transmit buffer is preserved in this case, and no data is written.

In addition to the interrupt flag TXC in USARTn\_IF and status flag TXC in USARTn\_STATUS which are set when the transmitter is idle, TXBL in USARTn\_STATUS and the TXBL interrupt flag in USARTn\_IF are used to indicate the level of the transmit buffer. TXBIL in USARTn\_CTRL controls the level at which these bits are set. If TXBIL is cleared, they are set whenever the transmit buffer becomes empty, and if TXBIL is set, they are set whenever the transmit buffer goes from full to half-full or empty. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when their condition becomes false.

The transmit buffer, including the transmit shift register can be cleared by setting CLEARTX in USARTn\_CMD. This will prevent the USART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed.

#### 17.3.2.3.2 Frame Transmission Control

The transmission control bits, which can be written using USARTn\_TXDATAX and USARTn\_TXDOUBLEX, affect the transmission of the written frame. The following options are available:

- Generate break: By setting TXBREAK, the output will be held low during the stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than a USART frame are thus not supported by the USART. GPIO can be used for this.
- Disable transmitter after transmission: If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- Enable receiver after transmission: If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.
- Unblock receiver after transmission: If UBRXAT is set, the receiver is unblocked and RXBLOCK is cleared after the frame has been fully transmitted.
- Tristate transmitter after transmission: If TXTRIAT is set, TXTRI is set after the frame has been fully transmitted, tristating the transmitter output. Tristating of the output can also be performed automatically by setting AUTOTRI. If AUTOTRI is set TXTRI is always read as 0.

**Note:** When in SmartCard mode with repeat enabled, none of the actions, except generate break, will be performed until the frame is transmitted without failure. Generation of a break in SmartCard mode with repeat enabled will cause the USART to detect a NACK on every frame.

### 17.3.2.4 Data Reception

Data reception is enabled by setting RXEN in USARTn\_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start baud of a new frame. When a start baud is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start baud. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available. If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the shift register is overwritten, and the RXOF interrupt flag in USARTn\_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in USARTn\_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in USARTn\_STATUS.

### 17.3.2.4.1 Receive Buffer Operation

When data becomes available in the receive buffer, the RXDATAV flag in USARTn\_STATUS, and the RXDATAV interrupt flag in USARTn\_IF are set, and when the buffer becomes full, RXFULL in USARTn\_STATUS and the RXFULL interrupt flag in USARTn\_IF are set. The status flags RXDATAV and RXFULL are automatically cleared by hardware when their condition is no longer true. This also goes for the RXDATAV interrupt flag, but the RXFULL interrupt flag must be cleared by software. When the RXFULL flag is set, notifying that the buffer is full, space is still available in the receive shift register for one more frame.

Data can be read from the receive buffer in a number of ways. USARTn\_RXDATA gives access to the 8 least significant bits of the received frame, and USARTn\_RXDOUBLE makes it possible to read the 8 least significant bits of two frames at once, pulling two frames from the buffer. To get access to the 9th, most significant bit, USARTn\_RXDATAX must be used. This register also contains status information regarding the frame. USARTn\_RXDOUBLEX can be used to get two frames complete with the 9th bits and status bits.

When a frame is read from the receive buffer using USARTn\_RXDATA or USARTn\_RXDATAX, the frame is pulled out of the buffer, making room for a new frame. USARTn\_RXDOUBLE and USARTn\_RXDOUBLEX pull two frames out of the buffer. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in USARTn\_IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can be read from the receive buffer without removing the data by using USARTn\_RXDATAXP and USARTn\_RXDOUBLEXP. USARTn\_RXDATAXP gives access the first frame in the buffer with status bits, while USARTn\_RXDOUBLEXP gives access to both frames with status bits. The data read from these registers when the receive buffer is empty is undefined. If the receive buffer contains one valid frame, the first frame in USARTn\_RXDOUBLEXP will be valid. No underflow interrupt is generated by a read using these registers, i.e. RXUF in USARTn\_IF is never set as a result of reading from USARTn\_RXDATAXP or USARTn\_RXDOUBLEXP.

The basic operation of the receive buffer when DATABITS in USARTn\_FRAME is configured to less than 10 bits is shown in the following figure.

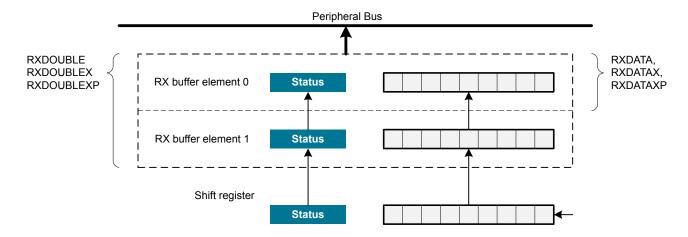

Figure 17.4. USART Receive Buffer Operation

The receive buffer, including the receive shift register can be cleared by setting CLEARRX in USARTn\_CMD. Any frame currently being received will not be discarded.

### 17.3.2.4.2 Blocking Incoming Data

When using hardware frame recognition, as detailed in 17.3.2.8 Multi-Processor Mode and 17.3.2.9 Collision Detection, it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in USARTn\_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV flag in USARTn\_STATUS or the RXDATAV interrupt flag in USARTn\_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in USARTn\_CMD and disabled by setting RXBLOCKDIS also in USARTn\_CMD. There is one exception where data is loaded into the receive buffer even when RXBLOCK is set. This is when an address frame is received when operating in multi-processor mode. See 17.3.2.8 Multi-Processor Mode for more information.

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in USARTn\_IF being set while RXBLOCK in USARTn\_STATUS is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

**Note:** If a frame is received while RXBLOCK in USARTn\_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time.

The overflow interrupt flag RXOF in USARTn\_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK in USARTn\_STATUS is set.

### 17.3.2.4.3 Clock Recovery and Filtering

The receiver samples the incoming signal at a rate 16, 8, 6 or 4 times higher than the given baud rate, depending on the oversampling mode given by OVS in USARTn CTRL. Lower oversampling rates make higher baud rates possible, but give less room for errors.

When a high-to-low transition is registered on the input while the receiver is idle, this is recognized as a start-bit, and the baud rate generator is synchronized with the incoming frame.

For oversampling modes 16, 8 and 6, every bit in the incoming frame is sampled three times to gain a level of noise immunity. These samples are aimed at the middle of the bit-periods, as visualized in the following figure. With OVS=0 in USARTn\_CTRL, the start and data bits are thus sampled at locations 8, 9 and 10 in the figure, locations 4, 5 and 6 for OVS=1 and locations 3, 4, and 5 for OVS=2. The value of a sampled bit is determined by majority vote. If two or more of the three bit-samples are high, the resulting bit value is high. If the majority is low, the resulting bit value is low.

Majority vote is used for all oversampling modes except 4x oversampling. In this mode, a single sample is taken at position 3 as shown in the following figure.

Majority vote can be disabled by setting MVDIS in USARTn CTRL.

If the value of the start bit is found to be high, the reception of the frame is aborted, filtering out false start bits possibly generated by noise on the input.

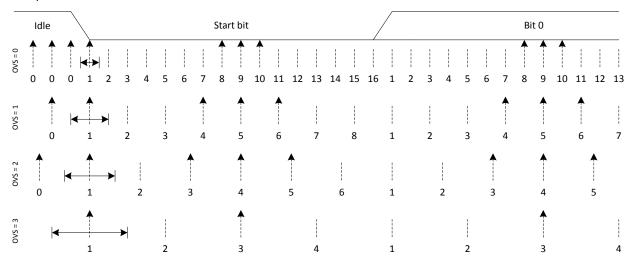

Figure 17.5. USART Sampling of Start and Data Bits

If the baud rate of the transmitter and receiver differ, the location each bit is sampled will be shifted towards the previous or next bit in the frame. This is acceptable for small errors in the baud rate, but for larger errors, it will result in transmission errors.

When the number of stop bits is 1 or more, stop bits are sampled like the start and data bits as seen in the following figure. When a stop bit has been detected by sampling at positions 8, 9 and 10 for normal mode, or 4, 5 and 6 for smart mode, the USART is ready for a new start bit. As seen in the following figure, a stop-bit of length 1 normally ends at c, but the next frame will be received correctly as long as the start-bit comes after position a for OVS=0 and OVS=3, and b for OVS=1 and OVS=2.

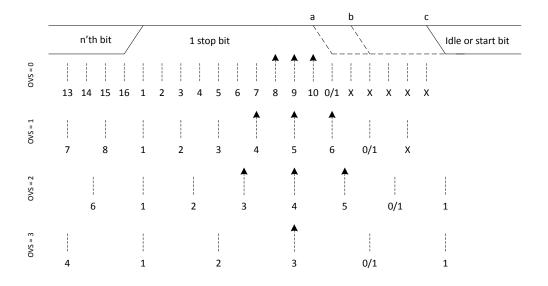

Figure 17.6. USART Sampling of Stop Bits when Number of Stop Bits are 1 or More

When working with stop bit lengths of half a baud period, the above sampling scheme no longer suffices. In this case, the stop-bit is not sampled, and no framing error is generated in the receiver if the stop bit is not generated. The line must still be driven high before the next start bit however for the USART to successfully identify the start bit.

### 17.3.2.4.4 Parity Error

When parity bits are enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in an incoming frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR in USARTn\_IF. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the USARTn\_RXDATAX, USARTn\_RXDATAXP, USARTn\_RXDOUBLEX or USARTn\_RXDOUBLEXP registers.

If ERRSTX in USARTn\_CTRL is set, the transmitter is disabled on received parity and framing errors. If ERRSRX in USARTn\_CTRL is set, the receiver is disabled on parity and framing errors.

### 17.3.2.4.5 Framing Error and Break Detection

A framing error is the result of an asynchronous frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected in an incoming frame, the framing error bit FERR in the frame is set. The interrupt flag FERR in USARTn\_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the USARTn\_RXDATAX, USARTn\_RXDATAXP, USARTn\_RXDOUBLEX or USARTn\_RXDOUBLEXP registers.

If ERRSTX in USARTn\_CTRL is set, the transmitter is disabled on parity and framing errors. If ERRSRX in USARTn\_CTRL is set, the receiver is disabled on parity and framing errors.

### 17.3.2.5 Local Loopback

The USART receiver samples U(S)n\_RX by default, and the transmitter drives U(S)n\_TX by default. This is not the only option however. When LOOPBK in USARTn\_CTRL is set, the receiver is connected to the U(S)n\_TX pin as shown in the following figure. This is useful for debugging, as the USART can receive the data it transmits, but it is also used to allow the USART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the U(S)n\_TX pin must be enabled as an output in the GPIO.

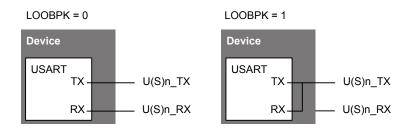

Figure 17.7. USART Local Loopback

#### 17.3.2.6 Asynchronous Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

### 17.3.2.6.1 Single Data-Link

In this setup, the USART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in USARTn\_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the USART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. This is done by setting the command bit TXTRIEN in USARTn\_CMD, which tristates the transmitter. Before transmitting data, the command bit TXTRI-DIS, also in USARTn\_CMD, must be set to enable transmitter output again. Whether or not the output is tristated at a given time can be read from TXTRI in USARTn\_STATUS. If TXTRI is set when transmitting data, the data is shifted out of the shift register, but is not put out on U(S)n\_TX.

When operating a half duplex data bus, it is common to have a bus master, which first transmits a request to one of the bus slaves, then receives a reply. In this case, the frame transmission control bits, which can be set by writing to USARTn\_TXDATAX, can be used to make the USART automatically disable transmission, tristate the transmitter and enable reception when the request has been transmitted, making it ready to receive a response from the slave.

Tristating the transmitter can also be performed automatically by the USART by using AUTOTRI in USARTn\_CTRL. When AUTOTRI is set, the USART automatically tristates U(S)n\_TX whenever the transmitter is idle, and enables transmitter output when the transmitter goes active. If AUTOTRI is set TXTRI is always read as 0.

**Note:** Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

### 17.3.2.6.2 Single Data-Link with External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of tristating the transmitter when receiving data, the external driver must be disabled.

This can be done manually by assigning a GPIO to turn the driver on or off, or it can be handled automatically by the USART. If AUTOCS in USARTn\_CTRL is set, the USn\_CS output is automatically activated one baud period before the transmitter starts transmitting data, and deactivated when the last bit has been transmitted and there is no more data in the transmit buffer to transmit, or the transmitter becomes disabled. This feature can be used to turn the external driver on when transmitting data, and turn it off when the data has been transmitted.

The following figure shows an example configuration where USn\_CS is used to automatically enable and disable an external driver.

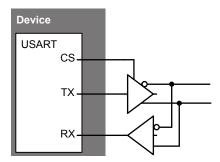

Figure 17.8. USART Half Duplex Communication with External Driver

The USn\_CS output is active low by default, but its polarity can be changed with CSINV in USARTn\_CTRL. AUTOCS works regardless of which mode the USART is in, so this functionality can also be used for automatic chip/slave select when in synchronous mode (e.g. SPI).

### 17.3.2.6.3 Two Data-Links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

### 17.3.2.7 Large Frames

As each frame in the transmit and receive buffers holds a maximum of 9 bits, both the elements in the buffers are combined when working with USART-frames of 10 or more data bits.

To transmit such a frame, at least two elements must be available in the transmit buffer. If only one element is available, the USART will wait for the second element before transmitting the combined frame. Both the elements making up the frame are consumed when transmitting such a frame.

When using large frames, the 9th bits in the buffers are unused. For an 11 bit frame, the 8 least significant bits are thus taken from the first element in the buffer, and the 3 remaining bits are taken from the second element as shown in the following figure. The first element in the transmit buffer, i.e. element 0 in the following figure is the first element written to the FIFO, or the least significant byte when writing two bytes at a time using USARTn TXDOUBLE.

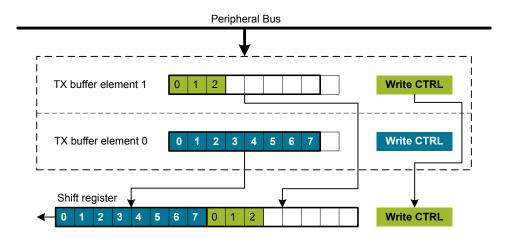

Figure 17.9. USART Transmission of Large Frames

As shown in the previous figure, frame transmission control bits are taken from the second element in FIFO.

The two buffer elements can be written at the same time using the USARTn\_TXDOUBLE or USARTn\_TXDOUBLEX register. The TXDATAX0 bitfield then refers to buffer element 0, and TXDATAX1 refers to buffer element 1.

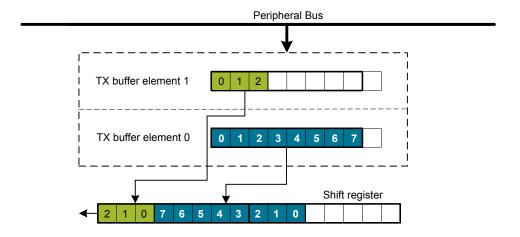

Figure 17.10. USART Transmission of Large Frames, MSBF

The previous figure illustrates the order of the transmitted bits when an 11 bit frame is transmitted with MSBF set. If MSBF is set and the frame is smaller than 10 bits, only the contents of transmit buffer 0 will be transmitted.

When receiving a large frame, BYTESWAP in USARTn\_CTRL determines the order the way the large frame is split into the two buffer elements. If BYTESWAP is cleared, the least significant 8 bits of the received frame are loaded into the first element of the receive buffer, and the remaining bits are loaded into the second element, as shown in the following figure. The first byte read from the buffer thus contains the 8 least significant bits. Set BYTESWAP to reverse the order.

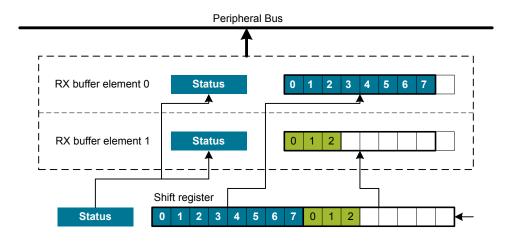

Figure 17.11. USART Reception of Large Frames

The status bits are loaded into both elements of the receive buffer. The frame is not moved from the receive shift register before there are two free spaces in the receive buffer.

The two buffer elements can be read at the same time using the USARTn\_RXDOUBLE or USARTn\_RXDOUBLEX register. RXDATA0 then refers to buffer element 0 and RXDATA1 refers to buffer element 1.

Large frames can be used in both asynchronous and synchronous modes.

### 17.3.2.8 Multi-Processor Mode

To simplify communication between multiple processors, the USART supports a special multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in USARTn\_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in USARTn\_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in USARTn\_STATUS.

Multi-processor mode is enabled by setting MPM in USARTn\_CTRL, and the value of the 9th bit in address frames can be set in MPAB. Note that the receiver must be enabled for address frames to be detected. The receiver can be blocked however, preventing data from being loaded into the receive buffer while looking for address frames.

The following example explains basic usage of the multi-processor mode:

- 1. All slaves enable multi-processor mode and, enable and block the receiver. They will now not receive data unless it is an address frame. MPAB in USARTn\_CTRL is set to identify frames with the 9th bit high as address frames.
- 2. The master sends a frame containing the address of a slave and with the 9th bit set.
- 3. All slaves receive the address frame and get an interrupt. They can read the address from the receive buffer. The selected slave unblocks the receiver to start receiving data from the master.
- The master sends data with the 9th bit cleared.
- 5. Only the slave with RX enabled receives the data. When transmission is complete, the slave blocks the receiver and waits for a new address frame.

When a slave has received an address frame and wants to receive the following data, it must make sure the receiver is unblocked before the next frame has been completely received in order to prevent data loss.

BIT8DV in USARTn\_CTRL can be used to specify the value of the 9th bit without writing to the transmit buffer with USARTn\_TXDATAX or USARTn\_TXDOUBLEX, giving higher efficiency in multi-processor mode, as the 9th bit is only set when writing address frames, and 8-bit writes to the USART can be used when writing the data frames.

#### 17.3.2.9 Collision Detection

The USART supports a basic form of collision detection. When the receiver is connected to the output of the transmitter, either by using the LOOPBK bit in USARTn\_CTRL or through an external connection, this feature can be used to detect whether data transmitted on the bus by the USART did get corrupted by a simultaneous transmission by another device on the bus.

For collision detection to be enabled, CCEN in USARTn\_CTRL must be set, and the receiver enabled. The data sampled by the receiver is then continuously compared with the data output by the transmitter. If they differ, the CCF interrupt flag in USARTn\_IF is set. The collision check includes all bits of the transmitted frames. The CCF interrupt flag is set once for each bit sampled by the receiver that differs from the bit output by the transmitter. When the transmitter output is disabled, i.e. the transmitter is tristated, collisions are not registered.

#### 17.3.2.10 SmartCard Mode

In SmartCard mode, the USART supports the ISO 7816 I/O line T0 mode. With exception of the stopbits (guard time), the 7816 data frame is equal to the regular asynchronous frame. In this mode, the receiver pulls the line low for one baud, half a baud into the guard time to indicate a parity error. This NAK can for instance be used by the transmitter to re-transmit the frame. SmartCard mode is a half duplex asynchronous mode, so the transmitter must be tristated whenever not transmitting data.

To enable SmartCard mode, set SCMODE in USARTn\_CTRL, set the number of databits in a frame to 8, and configure the number of stopbits to 1.5 by writing to STOPBITS in USARTn\_FRAME.

The SmartCard mode relies on half duplex communication on a single line, so for it to work, both the receiver and transmitter must work on the same line. This can be achieved by setting LOOPBK in USARTn\_CTRL or through an external connection. The TX output should be configured as open-drain in the GPIO module.

When no parity error is identified by the receiver, the data frame is as shown in the following figure. The frame consists of 8 data bits, a parity bit, and 2 stop bits. The transmitter does not drive the output line during the guard time.

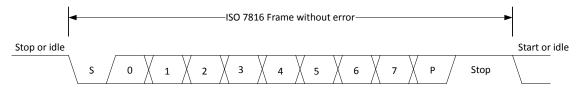

Figure 17.12. USART ISO 7816 Data Frame Without Error

If a parity error is detected by the receiver, it pulls the line I/O line low after half a stop bit, see the following figure. It holds the line low for one bit-period before it releases the line. In this case, the guard time is extended by one bit period before a new transmission can start, resulting in a total of 3 stop bits.

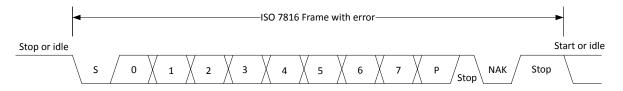

Figure 17.13. USART ISO 7816 Data Frame With Error

On a parity error, the NAK is generated by hardware. The NAK generated by the receiver is sampled as the stop-bit of the frame. Because of this, parity errors when in SmartCard mode are reported with both a parity error and a framing error.

When transmitting a T0 frame, the USART receiver on the transmitting side samples position 16, 17 and 18 in the stop-bit to detect the error signal when in 16x oversampling mode as shown in the following figure. Sampling at this location places the stop-bit sample in the middle of the bit-period used for the error signal (NAK).

If a NAK is transmitted by the receiver, it will thus appear as a framing error at the transmitter, and the FERR interrupt flag in USARTn\_IF will be set. If SCRETRANS USARTn\_CTRL is set, the transmitter will automatically retransmit a NACK'ed frame. The transmitter will retransmit the frame until it is ACK'ed by the receiver. This only works when the number of databits in a frame is configured to 8.

Set SKIPPERRF in USARTn\_CTRL to make the receiver discard frames with parity errors. The PERR interrupt flag in USARTn\_IF is set when a frame is discarded because of a parity error.

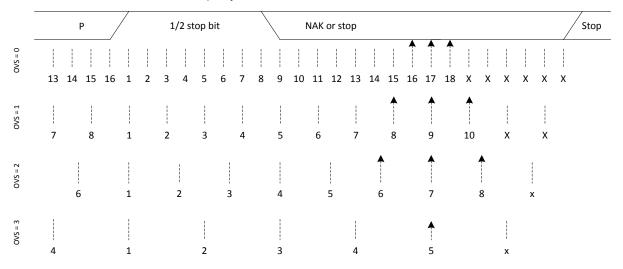

Figure 17.14. USART SmartCard Stop Bit Sampling

For communication with a SmartCard, a clock signal needs to be generated for the card. This clock output can be generated using one of the timers. See the ISO 7816 specification for more info on this clock signal.

SmartCard T1 mode is also supported. The T1 frame format used is the same as the asynchronous frame format with parity bit enabled and one stop bit. The USART must then be configured to operate in asynchronous half duplex mode.

### 17.3.3 Synchronous Operation

Most of the features in asynchronous mode are available in synchronous mode. Multi-processor mode can be enabled for 9-bit frames, loopback is available and collision detection can be performed.

#### 17.3.3.1 Frame Format

The frames used in synchronous mode need no start and stop bits since a single clock is available to all parts participating in the communication. Parity bits cannot be used in synchronous mode.

The USART supports frame lengths of 4 to 16 bits per frame. Larger frames can be simulated by transmitting multiple smaller frames, i.e. a 22 bit frame can be sent using two 11-bit frames, and a 21 bit frame can be generated by transmitting three 7-bit frames. The number of bits in a frame is set using DATABITS in USARTn FRAME.

The frames in synchronous mode are by default transmitted with the least significant bit first like in asynchronous mode. The bit-order can be reversed by setting MSBF in USARTn CTRL.

The frame format used by the transmitter can be inverted by setting TXINV in USARTn\_CTRL, and the format expected by the receiver can be inverted by setting RXINV, also in USARTn\_CTRL.

#### 17.3.3.2 Clock Generation

The bit-rate in synchronous mode is given by the following equation. As in the case of asynchronous operation, the clock division factor have a 13-bit integral part and a 2-bit fractional part.

$$br = \frac{f_{HFPERCLK}}{2 \times (1 + \frac{USARTn\_CLKDIV}{256})}$$

Given a desired baud rate brdesired, the clock divider USARTn CLKDIV can be calculated using the following equation.

USARTn\_CLKDIV = 256 × 
$$(\frac{f_{\text{HFPERCLK}}}{2 \times \text{brdesired}} - 1)$$

When the USART operates in master mode, the highest possible bit rate is half the peripheral clock rate. When operating in slave mode however, the highest bit rate is an eighth of the peripheral clock:

Master mode: br<sub>max</sub> = f<sub>HFPERCLK</sub>/2
 Slave mode: br<sub>max</sub> = f<sub>HFPERCLK</sub>/8

On every clock edge data on the data lines, MOSI and MISO, is either set up or sampled. When CLKPHA in USARTn\_CTRL is cleared, data is sampled on the leading clock edge and set-up is done on the trailing edge. If CLKPHA is set however, data is set-up on the leading clock edge, and sampled on the trailing edge. In addition to this, the polarity of the clock signal can be changed by setting CLKPOL in USARTn\_CTRL, which also defines the idle state of the clock. This results in four different modes which are summarized in the following table. The following figure shows the resulting timing of data set-up and sampling relative to the bus clock.

Table 17.8. USART SPI Modes

SPI mode	CLKPOL	СЬКРНА	Leading edge	Trailing edge
0	0	0	Rising, sample	Falling, set-up
1	0	1	Rising, set-up	Falling, sample
2	1	0	Falling, sample	Rising, set-up
3	1	1	Falling, set-up	Rising, sample

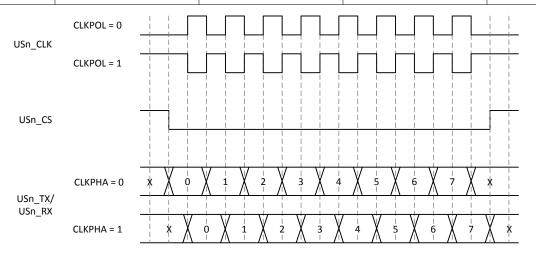

Figure 17.15. USART SPI Timing

If CPHA=1, the TX underflow flag, TXUF, will be set on the first setup clock edge of a frame in slave mode if TX data is not available. If CPHA=0, TXUF is set if data is not available in the transmit buffer three HFPERCLK cycles prior to the first sample clock edge. The RXDATAV flag is updated on the last sample clock edge of a transfer, while the RX overflow interrupt flag, RXOF, is set on the first sample clock edge if the receive buffer overflows. When a transfer has been performed, interrupt flags TXBL and TXC are updated on the first setup clock edge of the succeeding frame, or when CS is deasserted.

#### 17.3.3.3 Master Mode

When in master mode, the USART is in full control of the data flow on the synchronous bus. When operating in full duplex mode, the slave cannot transmit data to the master without the master transmitting to the slave. The master outputs the bus clock on USn CLK.

Communication starts whenever there is data in the transmit buffer and the transmitter is enabled. The USART clock then starts, and the master shifts bits out from the transmit shift register using the internal clock.

When there are no more frames in the transmit buffer and the transmit shift register is empty, the clock stops, and communication ends. When the receiver is enabled, it samples data using the internal clock when the transmitter transmits data. Operation of the RX and TX buffers is as in asynchronous mode.

### 17.3.3.3.1 Operation of USn\_CS Pin

When operating in master mode, the USn CS pin can have one of two functions, or it can be disabled.

If USn\_CS is configured as an output, it can be used to automatically generate a chip select for a slave by setting AUTOCS in USARTn\_CTRL. If AUTOCS is set, USn\_CS is activated when a transmission begins, and deactivated directly after the last bit has been transmitted and there is no more data in the transmit buffer. By default, USn\_CS is active low, but its polarity can be inverted by setting CSINV in USARTn\_CTRL.

When USn\_CS is configured as an input, it can be used by another master that wants control of the bus to make the USART release it. When USn\_CS is driven low, or high if CSINV is set, the interrupt flag SSM in USARTn\_IF is set, and if CSMA in USARTn\_CTRL is set, the USART goes to slave mode.

#### 17.3.3.3.2 AUTOTX

A synchronous master is required to transmit data to a slave in order to receive data from the slave. In some cases, only a few words are transmitted and a lot of data is then received from the slave. In that case, one solution is to keep feeding the TX with data to transmit, but that consumes system bandwidth. Instead AUTOTX can be used.

When AUTOTX in USARTn\_CTRL is set, the USART transmits data as long as there is available space in the RX shift register for the chosen frame size. This happens even though there is no data in the TX buffer. The TX underflow interrupt flag TXUF in USARTn\_IF is set on the first word that is transmitted which does not contain valid data.

During AUTOTX the USART will always send the previous sent bit, thus reducing the number of transitions on the TX output. So if the last bit sent was a 0, 0's will be sent during AUTOTX and if the last bit sent was a 1, 1's will be sent during AUTOTX.

### 17.3.3.3.3 Synchronous Master Sample Delay

To improve speed in certain conditions by reducing the setup-time requirements for the SPI slave, the master can be configured to sample the data one half SCLK-cycle later, i.e. on the next setup edge, which, in SPI mode 0, is the rising edge. This is enabled by setting SMSDELAY in USARTn\_CTRL and can be used together with all SPI slaves that does not set up new data before the next setup edge, as the propagation delay of SCLK will ensure sufficient hold time.

Note: If used together with another Silicon Laboratories chip utilizing SSSEARLY, a very thorough understanding of the timing is required.

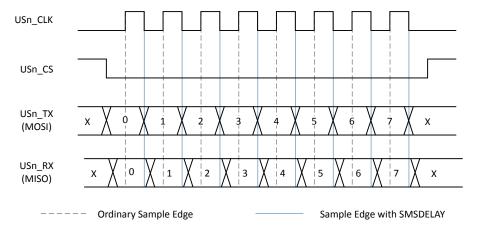

Figure 17.16. USART SPI Timing with SMSDELAY

#### 17.3.3.4 Slave Mode

When the USART is in slave mode, data transmission is not controlled by the USART, but by an external master. The USART is therefore not able to initiate a transmission, and has no control over the number of bytes written to the master.

The output and input to the USART are also swapped when in slave mode, making the receiver take its input from USn\_TX (MOSI) and the transmitter drive USn\_RX (MISO).

To transmit data when in slave mode, the slave must load data into the transmit buffer and enable the transmitter. The data will remain in the USART until the master starts a transmission by pulling the USn\_CS input of the slave low and transmitting data. For every frame the master transmits to the slave, a frame is transferred from the slave to the master. After a transmission, MISO remains in the same state as the last bit transmitted. This also applies if the master transmits to the slave and the slave TX buffer is empty.

If the transmitter is enabled in synchronous slave mode and the master starts transmission of a frame, the underflow interrupt flag TXUF in USARTn IF will be set if no data is available for transmission to the master.

If the slave needs to control its own chip select signal, this can be achieved by clearing CSPEN in the ROUTE register. The internal chip select signal can then be controlled through CSINV in the CTRL register. The chip select signal will be CSINV inverted, i.e. if CSINV is cleared, the chip select is active and vice versa.

### 17.3.3.4.1 Synchronous Slave Setup Early

To improve speed in certain conditions by improving the setup time when running in slave mode, the slave can be configured to set up data one half SCLK-cycle earlier, i.e. on the previous sample edge, which, for SPI mode 0, is the falling edge. This is enabled by setting SSSEARLY in USARTn\_CTRL and can be used with all SPI masters that samples the data on the sample edge, as the SCLK propagation delay will ensure sufficient hold time.

**Note:** If used together with another Silicon Laboratories chip utilizing SMSDELAY, a very thorough understanding of the timing is required.

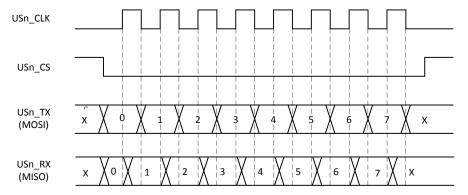

Figure 17.17. USART SPI Slave Timing with SSSEARLY

#### 17.3.3.5 Synchronous Half Duplex Communication

Half duplex communication in synchronous mode is very similar to half duplex communication in asynchronous mode as detailed in 17.3.2.6 Asynchronous Half Duplex Communication. The main difference is that in this mode, the master must generate the bus clock even when it is not transmitting data, i.e. it must provide the slave with a clock to receive data. To generate the bus clock, the master should transmit data with the transmitter tristated, i.e. TXTRI in USARTn\_STATUS set, when receiving data. If 2 bytes are expected from the slave, then transmit 2 bytes with the transmitter tristated, and the slave uses the generated bus clock to transmit data to the master. TXTRI can be set by setting the TXTRIEN command bit in USARTn\_CMD.

**Note:** When operating as SPI slave in half duplex mode, TX has to be tristated (not disabled) during data reception if the slave is to transmit data in the current transfer.

### 17.3.3.6 I2S

I2S is a synchronous format for transmission of audio data. The frame format is 32-bit, but since data is always transmitted with MSB first, an I2S device operating with 16-bit audio may choose to only process the 16 msb of the frame, and only transmit data in the 16 msb of the frame.

In addition to the bit clock used for regular synchronous transfers, I2S mode uses a separate word clock. When operating in mono mode, with only one channel of data, the word clock pulses once at the start of each new word. In stereo mode, the word clock toggles at the start of new words, and also gives away whether the transmitted word is for the left or right audio channel; A word transmitted while the word clock is low is for the left channel, and a word transmitted while the word clock is high is for the right.

When operating in I2S mode, the CS pin is used as a the word clock. In master mode, this is automatically driven by the USART, and in slave mode, the word clock is expected from an external master.

### 17.3.3.6.1 Word Format

The general I2S word format is 32 bits wide, but the USART also supports 16-bit and 8-bit words. In addition to this, it can be specified how many bits of the word should actually be used by the USART. These parameters are given by FORMAT in USARTn I2SCTRL.

As an example, configuring FORMAT to using a 32-bit word with 16-bit data will make each word on the I2S bus 32-bits wide, but when receiving data through the USART, only the 16 most significant bits of each word can be read out of the USART. Similarly, only the 16 most significant bits have to be written to the USART when transmitting. The rest of the bits will be transmitted as zeroes.

### 17.3.3.6.2 Major Modes

The USART supports a set of different I2S formats as shown in the following table, but it is not limited to these modes. MONO, JUSTI-FY and DELAY in USARTn\_I2SCTRL can be mixed and matched to create an appropriate format. MONO enables mono mode, i.e. one data stream instead of two which is the default. JUSTIFY aligns data within a word on the I2S bus, either left or right which can bee seen in the following figures. Finally, DELAY specifies whether a new I2S word should be started directly on the edge of the word-select signal, or one bit-period after the edge.

Regular I2S	0	0	1	0	
Mode	MONO	JUSTIFY	DELAY	CLKPOL	
Left-Justified	0	0	0	1	
Right-Justified	0	1	0	1	
Mono	1	0	0	0	

Table 17.9. USART I2S Modes

The regular I2S waveform is shown in the following figures. The first figure shows a waveform transmitted with full accuracy. The wordlength can be configured to 32-bit, 16-bit or 8-bit using FORMAT in USARTn\_I2SCTRL. In the second figure, I2S data is transmitted with reduced accuracy, i.e. the data transmitted has less bits than what is possible in the bus format.

Note that the msb of a word transmitted in regular I2S mode is delayed by one cycle with respect to word select.

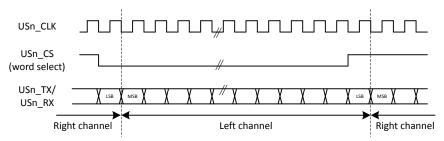

Figure 17.18. USART Standard I2S Waveform

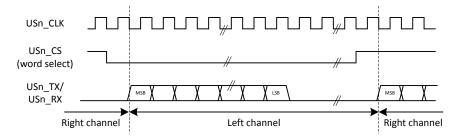

Figure 17.19. USART Standard I2S Waveform (Reduced Accuracy)

A left-justified stream is shown in the following figure. Note that the MSB comes directly after the edge on the word-select signal in contradiction to the regular I2S waveform where it comes one bitperiod after.

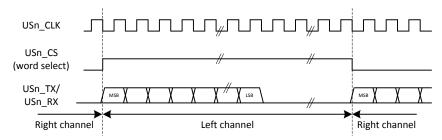

Figure 17.20. USART Left-Justified I2S Waveform

A right-justified stream is shown in the following figure. The left and right justified streams are equal when the data-size is equal to the word-width.

Figure 17.21. USART Right-Justified I2S Waveform

In mono-mode, the word-select signal pulses at the beginning of each word instead of toggling for each word. Mono I2S waveform is shown in the following figure.

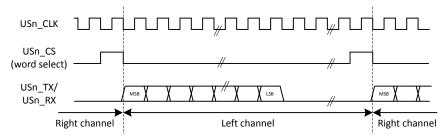

Figure 17.22. USART Mono I2S Waveform

### 17.3.3.6.3 Using I2S Mode

When using the USART in I2S mode, DATABITS in USARTn\_FRAME must be set to 8 or 16 data-bits. 8 databits can be used in all modes, and 16 can be used in the modes where the number of bytes in the I2S word is even. In addition to this, MSBF in USARTn\_CTRL should be set, and CLKPOL and CLKPHA in USARTn\_CTRL should be cleared.

The USART does not have separate TX and RX buffers for left and right data, so when using I2S in stereo mode, the application must keep track of whether the buffers contain left or right data. This can be done by observing TXBLRIGHT, RXDATAVRIGHT and RXFULLRIGHT in USARTn\_STATUS. TXBLRIGHT tells whether TX is expecting data for the left or right channel. It will be set with TXBL if right data is expected. The receiver will set RXDATAVRIGHT if there is at least one right element in the buffer, and RXFULL-RIGHT if the buffer is full of right elements.

When using I2S with DMA, separate DMA requests can be used for left and right data by setting DMASPLIT in USARTn\_I2SCTRL.

In both master and slave mode the USART always starts transmitting on the LEFT channel after being enabled. In master mode, the transmission will stop if TX becomes empty. In that case, TXC is set. Continuing the transmission in this case will make the data-stream continue where it left off. To make the USART start on the LEFT channel after going empty, disable and re-enable TX.

## 17.3.4 PRS-Triggered Transmissions

If a transmission must be started on an event with very little delay, the PRS system can be used to trigger the transmission. The PRS channel to use as a trigger can be selected using TSEL in USARTn\_TRIGCTRL. When a positive edge is detected on this signal, the receiver is enabled if RXTEN in USARTn\_TRIGCTRL is set, and the transmitter is enabled if TXTEN in USARTn\_TRIGCTRL is set. Only one signal input is supported by the USART.

The AUTOTX feature can also be enabled via PRS. If an external SPI device sets a pin high when there is data to be read from the device, this signal can be routed to the USART through the PRS system and be used to make the USART clock data out of the external device. If AUTOTXTEN in USARTn\_TRIGCTRL is set, the USART will transmit data whenever the PRS signal selected by TSEL is high given that there is enough room in the RX buffer for the chosen frame size. Note that if there is no data in the TX buffer when using AUTOTX, the TX underflow interrupt will be set.

AUTOTXTEN can also be combined with TXTEN to make the USART transmit a command to the external device prior to clocking out data. To do this, disable TX using the TXDIS command, load the TX buffer with the command and enable AUTOTXTEN and TXTEN. When the selected PRS input goes high, the USART will now transmit the loaded command, and then continue clocking out while both the PRS input is high and there is room in the RX buffer.

### 17.3.5 PRS RX Input

The USART can be configured to receive data directly from a PRS channel by setting RXPRS in USARTn\_INPUT. The PRS channel used is selected using RXPRSSEL in USARTn\_INPUT. This way, for example, a differential RX signal can be input to the ACMP and the output routed via PRS to the USART.

### 17.3.6 DMA Support

The USART has full DMA support. The DMA controller can write to the transmit buffer using the registers USARTn\_TXDATA, USARTn\_TXDOUBLE and USARTn\_TXDOUBLEX, and it can read from the receive buffer using the registers USARTn\_RXDATA, USARTn\_RXDATAX, USARTn\_RXDOUBLE and USARTn\_RXDOUBLEX. This enables single byte transfers, 9 bit data + control/status bits, double byte and double byte + control/status transfers both to and from the USART.

A request for the DMA controller to read from the USART receive buffer can come from the following source:

- · Data available in the receive buffer.
- Data available in the receive buffer and data is for the RIGHT I2S channel. Only used in I2S mode.

A write request can come from one of the following sources:

- Transmit buffer and shift register empty. No data to send.
- · Transmit buffer has room for more data.
- · Transmit buffer has room for RIGHT I2S data. Only used in I2S mode.

Even though there are two sources for write requests to the DMA, only one should be used at a time, since the requests from both sources are cleared even though only one of the requests are used.

In some cases, it may be sensible to temporarily stop DMA access to the USART when an error such as a framing error has occurred. This is enabled by setting ERRSDMA in USARTn CTRL.

### 17.3.7 Transmission Delay

By configuring TXDELAY in USARTn\_CTRL, the transmitter can be forced to wait a number of bitperiods from it is ready to transmit data, to it actually transmits the data. This delay is only applied to the first frame transmitted after the transmitter has been idle. When transmitting frames back-to-back the delay is not introduced between the transmitted frames.

This is useful on half duplex buses, because the receiver always returns received frames to software during the first stop-bit. The bus may still be driven for up to 3 baud periods, depending on the current frame format. Using the transmission delay, a transmission can be started when a frame is received, and it is possible to make sure that the transmitter does not begin driving the output before the frame on the bus is completely transmitted.

TXDELAY in USARTn\_CTRL only applies to asynchronous transmission.

### 17.3.8 Interrupts

The interrupts generated by the USART are combined into two interrupt vectors. Interrupts related to reception are assigned to one interrupt vector, and interrupts related to transmission are assigned to the other. Separating the interrupts in this way allows different priorities to be set for transmission and reception interrupts.

The transmission interrupt vector groups the transmission-related interrupts generated by the following interrupt flags:

- TXC
- TXBL
- TXOF
- CCF

The reception interrupt on the other hand groups the reception-related interrupts, triggered by the following interrupt flags:

- RXDATAV
- RXFULL
- RXOF
- RXUF
- PERR
- FERR
- . \_. . .
- MPAF
- SSM

If USART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in USART\_IF and their corresponding bits in USART\_IEN are set.

#### 17.3.9 IrDA Modulator/Demodulator

The IrDA modulator on USART0 implements the physical layer of the IrDA specification, which is necessary for communication over IrDA. The modulator takes the signal output from the USART module, and modulates it before it leaves USART0. In the same way, the input signal is demodulated before it enters the actual USART module. The modulator is only available on USART0, and implements the original Rev. 1.0 physical layer and one high speed extension which supports speeds from 2.4 kbps to 1.152 Mbps.

The data from and to the USART is represented in a NRZ (Non Return to Zero) format, where the signal value is at the same level through the entire bit period. For IrDA, the required format is RZI (Return to Zero Inverted), a format where a "1" is signalled by holding the line low, and a "0" is signalled by a short high pulse. An example is given in the following figure.

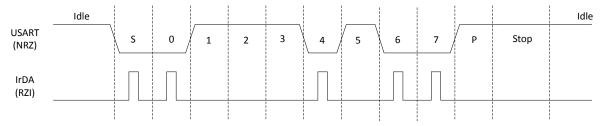

Figure 17.23. USART Example RZI Signal for a Given Asynchronous USART Frame

The IrDA module is enabled by setting IREN. The USART transmitter output and receiver input is then routed through the IrDA modulator.

The width of the pulses generated by the IrDA modulator is set by configuring IRPW in USARTn\_IRCTRL. Four pulse widths are available, each defined relative to the configured bit period as listed in the following table.

IRPW	Pulse width OVS=0	Pulse width OVS=1	Pulse width OVS=2	Pulse width OVS=3
00	1/16	1/8	1/6	1/4
01	2/16	2/8	2/6	N/A
10	3/16	3/8	N/A	N/A
11	4/16	N/A	N/A	N/A

Table 17.10. USART IrDA Pulse Widths

By default, no filter is enabled in the IrDA demodulator. A filter can be enabled by setting IRFILT in USARTn\_IRCTRL. When the filter is enabled, an incoming pulse has to last for 4 consecutive clock cycles to be detected by the IrDA demodulator.

Note that by default, the idle value of the USART data signal is high. This means that the IrDA modulator generates negative pulses, and the IrDA demodulator expects negative pulses. To make the IrDA module use RZI signalling, both TXINV and RXINV in USARTn CTRL must be set.

The IrDA module can also modulate a signal from the PRS system, and transmit a modulated signal to the PRS system. To use a PRS channel as transmitter source instead of the USART, set IRPRSEN in USARTn\_IRCTRL high. The channel is selected by configuring IRPRSSEL in USARTn\_IRCTRL.

# 17.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

Received framing and parity errors have no effect on transmitter

Bit	Name	Reset	Access	Description
	1			Received framing and parity errors disable the transmitter
23	ERRSRX	0	RW	Disable RX On Error
	When set, the rece	iver is disabled	on framing ar	nd parity errors (asynchronous mode only).
	Value			Description
	0			Framing and parity errors have no effect on receiver
	1			Framing and parity errors disable the receiver
22	ERRSDMA	0	RW	Halt DMA On Error
	When set, DMA red	quests will be cle	eared on fram	ning and parity errors (asynchronous mode only).
	Value			Description
	0			Framing and parity errors have no effect on DMA requests from the USART
	1			DMA requests from the USART are blocked while the PERR or FERR interrupt flags are set
21	BIT8DV	0	RW	Bit 8 Default Value
	The default value o			re used, and an 8-bit write operation is done, leaving the 9th bit unspecified,
20	SKIPPERRF	0	RW	Skip Parity Error Frames
	When set, the rece	iver discards fra	mes with par	ity errors (asynchronous mode only). The PERR interrupt flag is still set.
19	SCRETRANS	0	RW	SmartCard Retransmit
	When in SmartCard bled.	d mode, a NACł	C'ed frame wi	Il be kept in the shift register and retransmitted if the transmitter is still ena-
18	SCMODE	0	RW	SmartCard Mode
	Use this bit to enab	le or disable Sn	nartCard mod	e.
17	AUTOTRI	0	RW	Automatic TX Tristate
	When enabled, TX mission starts.	TRI is set by ha	rdware whene	ever the transmitter is idle, and TXTRI is cleared by hardware when trans-
	Value			Description
	0			The output on U(S)n_TX when the transmitter is idle is defined by TXINV
	1			U(S)n_TX is tristated whenever the transmitter is idle
16	AUTOCS	0	RW	Automatic Chip Select
	When enabled, the transmission ends.	output on USn_	_CS will be ad	ctivated one baud-period before transmission starts, and deactivated when
15	CSINV	0	RW	Chip Select Invert
	Default value is act as a slave.	ive low. This aff	ects both the	selection of external slaves, as well as the selection of the microcontroller
	Value			Description
	0			Chip select is active low

Bit	Name	Reset	Access	Description
	1			Chip select is active high
14	TXINV	0	RW	Transmitter output Invert
	The output from	the USART transm	nitter can opti	ionally be inverted by setting this bit.
	Value			Description
	0			Output from the transmitter is passed unchanged to U(S)n_TX
	1			Output from the transmitter is inverted before it is passed to U(S)n_TX
13	RXINV	0	RW	Receiver Input Invert
	Setting this bit w	ill invert the input to	o the USART	receiver.
	Value			Description
	0			Input is passed directly to the receiver
	1			Input is inverted before it is passed to the receiver
12	TXBIL	0	RW	TX Buffer Interrupt Level
	Determines the i	nterrupt and status	level of the	transmit buffer.
	Value	Mode		Description
	0	EMPTY		TXBL and the TXBL interrupt flag are set when the transmit buffer becomes empty. TXBL is cleared when the buffer becomes nonempty.
	1	HALFFULL		TXBL and TXBLIF are set when the transmit buffer goes from full to half-full or empty. TXBL is cleared when the buffer becomes full.
11	CSMA	0	RW	Action On Slave-Select In Master Mode
	This register dete master mode.	ermines the action	to be perforn	med when slave-select is configured as an input and driven low while in
	Value	Mode		Description
	0	NOACTION	I	No action taken
	1	GOTOSLA	/EMODE	Go to slave mode
10	MSBF	0	RW	Most Significant Bit First
	Decides whether	data is sent with t	he least sign	ificant bit first, or the most significant bit first.
	Value			Description
	0			Data is sent with the least significant bit first
	1			Data is sent with the most significant bit first
9	CLKPHA	0	RW	Clock Edge For Setup/Sample
	Determines whe	re data is set-up ar	nd sampled a	according to the bus clock when in synchronous mode.
	Value	Mode		Description
	0	SAMPLELE	ADING	Data is sampled on the leading edge and set-up on the trailing edge of the bus clock in synchronous mode

1 SAMPLETRAILING Data is set-up on the leading edge and sampled on the trailing edge of the bus clock in synchronous mode  8 CLKPOL 0 RW Clock Polarity Determines the clock polarity of the bus clock used in synchronous mode.  Value Mode Description 0 IDLELOW The bus clock used in synchronous mode has a low base value 1 IDLEHIGH The bus clock used in synchronous mode has a low base value 1 IDLEHIGH The bus clock used in synchronous mode has a low base value 7 Reserved To ensure compatibility with future devices, always write bits to 0. More information in 2.1 Conventions.  6:5 OVS 0x0 RW Oversampling Sets the number of clock periods in a UART bit-period. More clock cycles gives better robustness, while less clock cycles gives better performance.  Value Mode Description 0 X16 Regular UART mode with 18X oversampling in asynchronous mode 1 X8 Double speed with 8X oversampling in asynchronous mode 2 X6 6X oversampling in asynchronous mode 3 X4 Quadruple speed with 4X oversampling in asynchronous mode 4 MPAB 0 RW Multi-Processor Addross-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame Value Description 0 The 9th bit of incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check is disabled 1 Collision check is disabled 1 Collision check is disabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description 0 The receiver is connected to and receives data from U(S)n RX	Bit	Name	Reset	Access	Description
Determines the clock polarity of the bus clock used in synchronous mode.  Value Mode Description  0 IDLELOW The bus clock used in synchronous mode has a low base value  1 IDLEHIGH The bus clock used in synchronous mode has a low base value  7 Reserved To ensure compatibility with furture devices, always write bits to 0. More information in 2.1 Conventions.  8:5 OVS 0x0 RW Oversampling  Sets the number of clock periods in a UART bit-period. More clock cycles gives better robustness, while less clock cycles gives better performance.  Value Mode Description  0 X16 Regular UART mode with 16X oversampling in asynchronous mode  1 X8 Double speed with 8X oversampling in asynchronous mode  2 X6 6 X oversampling in asynchronous mode  3 X4 Quadruple speed with 4X oversampling in asynchronous mode  4 MPAB 0 RW Multi-Processor Address-Bit Defines the value of the multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode  Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value Description  2 CCEN 0 RW Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  1 Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  1 Collision Check is disabled  1 Collision check is disabled. The receiver must be enabled for the check to be performed.  1 LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.		1	SAMPLETRA	ILING	
Value   Mode   Description	8	CLKPOL	0	RW	Clock Polarity
1   IDLELOW   The bus clock used in synchronous mode has a low base value		Determines the clock	polarity of the b	us clock us	sed in synchronous mode.
The bus clock used in synchronous mode has a high base value		Value	Mode		Description
Reserved   To ensure compatibility with future devices, always write bits to 0. More information in 2.1 Conventions.		0	IDLELOW		The bus clock used in synchronous mode has a low base value
6:5 OVS 0x0 RW Oversampling  Sets the number of clock periods in a UART bit-period. More clock cycles gives better robustness, while less clock cycles gives better performance.  Value Mode Description  0 X16 Regular UART mode with 16X oversampling in asynchronous mode 1 X8 Double speed with 8X oversampling in asynchronous mode 2 X6 6X oversampling in asynchronous mode 3 X4 Quadruple speed with 4X oversampling in asynchronous mode 4 MPAB 0 RW Multi-Processor Address-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame Value Description 0 The 9th bit of incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description 0 Collision check is disabled 1 Collision check is enabled. The receiver must be enabled for the check to be performed Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.		1	IDLEHIGH		The bus clock used in synchronous mode has a high base value
Sets the number of clock periods in a UART bit-period. More clock cycles gives better robustness, while less clock cycles gives better performance.  Value Mode Description  0 X16 Regular UART mode with 16X oversampling in asynchronous mode  1 X8 Double speed with 8X oversampling in asynchronous mode  2 X6 6X oversampling in asynchronous mode  3 X4 Quadruple speed with 4X oversampling in asynchronous mode  4 MPAB 0 RW Multi-Processor Address-Bit  Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode  Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value Description  1 An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  0 Collision check is disabled  1 Collision check is enabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.	7	Reserved		npatibility (	with future devices, always write bits to 0. More information in 2.1 Conven-
Value   Mode   Description	6:5	OVS	0x0	RW	Oversampling
0 X16 Regular UART mode with 16X oversampling in asynchronous mode 1 X8 Double speed with 8X oversampling in asynchronous mode 2 X6 6X oversampling in asynchronous mode 3 X4 Quadruple speed with 4X oversampling in asynchronous mode 4 MPAB 0 RW Multi-Processor Address-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame Value Description 0 The 9th bit of incoming frames has no special function 1 An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description 1 Collision check is disabled 1 Collision check is enabled. The receiver must be enabled for the check to be performed  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication. 1 X8 Double speed with 8X oversampling in asynchronous mode 2 X6 6X oversampling in asynchronous mode 3 X4 Quadruple speed with 4X oversampling in asynchronous mode 4 MPAB 0 RW Multt-Processor Address-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame Value Description 0 The 9th bit of incoming frames has no special function 1 An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description  1 Collision check is disabled 1 Collision check is enabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		Value	Mode		Description
2 X6 6X oversampling in asynchronous mode 3 X4 Quadruple speed with 4X oversampling in asynchronous mode 4 MPAB 0 RW Multi-Processor Address-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value Description 0 The 9th bit of incoming frames has no special function 1 An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description 0 Collision check is disabled 1 Collision check is enabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		0	X16		Regular UART mode with 16X oversampling in asynchronous mode
3 X4 Quadruple speed with 4X oversampling in asynchronous mode  4 MPAB 0 RW Multi-Processor Address-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value Description  1 The 9th bit of incoming frames has no special function An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description  0 Collision check is disabled 1 Collision check is enabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		1	X8		Double speed with 8X oversampling in asynchronous mode
A MPAB 0 RW Multi-Processor Address-Bit Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  MPM 0 RW Multi-Processor Mode Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame Value Description Description  The 9th bit of incoming frames has no special function  An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description Collision check is disabled Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK 0 RW Loopback Enable Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		2	X6		6X oversampling in asynchronous mode
Defines the value of the multi-processor address bit. An incoming frame with its 9th bit equal to the value of this bit marks the frame as a multi-processor address frame.  3 MPM 0 RW Multi-Processor Mode  Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value Description  1 The 9th bit of incoming frames has no special function  1 An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  0 Collision check is disabled  1 Collision check is enabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		3	X4		Quadruple speed with 4X oversampling in asynchronous mode
the frame as a multi-processor address frame.  MPM 0 RW Multi-Processor Mode  Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value Description  The 9th bit of incoming frames has no special function  An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  CCEN 0 RW Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description	4	MPAB	0	RW	Multi-Processor Address-Bit
Multi-processor mode uses the 9th bit of the USART frames to tell whether the frame is an address frame or a data frame  Value  Description  The 9th bit of incoming frames has no special function  An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  CCEN  RW  Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value  Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK  RW  Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value  Description					s bit. An incoming frame with its 9th bit equal to the value of this bit marks
Value  Description  The 9th bit of incoming frames has no special function  An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  CCEN  RW  Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value  Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK  RW  Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value  Description	3	MPM	0	RW	Multi-Processor Mode
The 9th bit of incoming frames has no special function  An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  CCEN 0 RW Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		Multi-processor mode	e uses the 9th bi	t of the US	ART frames to tell whether the frame is an address frame or a data frame.
An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  2 CCEN 0 RW Collision Check Enable Enables collision checking on data when operating in half duplex modus.  Value Description  0 Collision check is disabled  1 Collision check is enabled. The receiver must be enabled for the check to be performed  1 LOOPBK 0 RW Loopback Enable Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		Value			Description
the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set  CCEN 0 RW Collision Check Enable  Enables collision checking on data when operating in half duplex modus.  Value Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		0			The 9th bit of incoming frames has no special function
Enables collision checking on data when operating in half duplex modus.  Value  Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK  RW  Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value  Description		1			the receive buffer regardless of RXBLOCK and will result in the MPAB
Value  Description  Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK  RW  Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value  Description	2	CCEN	0	RW	Collision Check Enable
Collision check is disabled  Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK 0 RW Loopback Enable Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		Enables collision che	cking on data wl	nen operat	ing in half duplex modus.
Collision check is enabled. The receiver must be enabled for the check to be performed  LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		Value			Description
to be performed  LOOPBK 0 RW Loopback Enable  Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value Description		0			Collision check is disabled
Allows the receiver to be connected directly to the USART transmitter for loopback and half duplex communication.  Value  Description		1			
Value Description	1	LOOPBK	0	RW	Loopback Enable
		Allows the receiver to	be connected d	lirectly to th	ne USART transmitter for loopback and half duplex communication.
0 The receiver is connected to and receives data from U(S)n RX		Value			Description
		0			The receiver is connected to and receives data from U(S)n_RX

12	CCF	0	R	Collision Check Fail Interrupt Flag
	Set when a collis	ion check notices	an error in th	e transmitted data.
11	SSM	0	R	Slave-Select In Master Mode Interrupt Flag
	Set when the dev	vice is selected as	s a slave wher	n in master mode.
10	MPAF	0	R	Multi-Processor Address Frame Interrupt Flag
	Set when a multi-	processor addre	ss frame is de	etected.
9	FERR	0	R	Framing Error Interrupt Flag
	Set when a frame	e with a framing e	error is receive	ed while RXBLOCK is cleared.
8	PERR	0	R	Parity Error Interrupt Flag
	Set when a frame	e with a parity erro	or (asynchron	ous mode only) is received while RXBLOCK is cleared.
7	TXUF	0	R	TX Underflow Interrupt Flag
	Set when operati of a new frame.	ng as a synchron	ous slave, no	data is available in the transmit buffer when the master starts transmission
6	TXOF	0	R	TX Overflow Interrupt Flag
	Set when a write	is done to the tra	nsmit buffer w	while it is full. The data already in the transmit buffer is preserved.
5	RXUF	0	R	RX Underflow Interrupt Flag
	Set when trying to	o read from the re	eceive buffer v	when it is empty.
4	RXOF	0	R	RX Overflow Interrupt Flag
	Set when data is	incoming while th	ne receive shit	ft register is full. The data previously in the shift register is lost.
3	RXFULL	0	R	RX Buffer Full Interrupt Flag
	Set when the rec	eive buffer becon	nes full.	
2	RXDATAV	0	R	RX Data Valid Interrupt Flag
	Set when data be	ecomes available	in the receive	buffer.
1	TXBL	1	R	TX Buffer Level Interrupt Flag
	Set when the buf empty if TXBIL is		oty if TXBIL is	cleared, and is set whenever the transmit buffer goes from full to half-full or
0	TXC	0	R	TX Complete Interrupt Flag
	This interrupt is u	sed after a transi	mission when	both the TX buffer and shift register are empty.

# 18. UART - Universal Asynchronous Receiver/ Transmitter

#### **Quick Facts**

## What?

The UART is capable of high-speed asynchronous serial communication

## Why?

Serial communication is frequently used in embedded systems and the UART allows efficient communication with a wide range of external devices.

## How?

The UART has a wide selection of operating modes, frame formats and baud rates. The multi-processor mode allows the UART to remain idle when not addressed. Triple buffering and DMA support makes high datarates possible with minimal CPU intervention and it is possible to transmit and receive large frames while the MCU remains in EM1.

## 18.1 Introduction

The Universal Asynchronous serial Receiver and Transmitter (UART) is a very flexible serial I/O module. It supports full- and half-duplex asynchronous UART communication.

#### 18.2 Features

- · Full duplex and half duplex
- · Separate TX / RX enable
- Separate receive / transmit 2-level buffers, with additional separate shift registers
- Programmable baud rate, generated as an fractional division from the peripheral clock (HFPERCLK)
- · Max bit-rate
  - · UART standard mode, peripheral clock rate / 16
  - UART FAST mode, peripheral clock rate / 8
- · Asynchronous mode supports
  - · Majority vote baud-reception
  - · False start-bit detection
  - · Break generation/detection
  - · Multi-processor mode
- Configurable number of data bits, 4-16 (plus the parity bit, if enabled)
  - · HW parity bit generation and check
- Configurable number of stop bits in asynchronous mode: 0.5, 1, 1.5, 2
- · HW collision detection
- · Multi-processor mode
- · Separate interrupt vectors for receive and transmit interrupts
- · Loopback mode
  - · Half duplex communication
  - · Communication debugging
- · PRS can trigger transmissions
- Full DMA support
- · PRS RX input

## 18.3 Functional Description

The UART is functionally equivalent to the USART with the exceptions defined in the following table. The register map and register descriptions are equal to those of the USART. See the USART chapter for detailed information on the operation of the UART.

Table 18.1. UART Limitations

Feature	Limitation
Synchronous operation	Not available. SYNC, CSMA, SMSDELAY, SSSEARLY, CSINV, CPOL and CPHA in USARTn_CTRL, and MASTEREN in USARTn_STATUS are always 0.
Transmission direction	Always LSB first. MSBF in USARTn_CTRL is always 0.
Chip-select	Not available. AUTOCS in USARTn_CTRL is always 0.
SmartCard mode	Not available. SCMODE in USARTn_CTRL is always 0.
Frame size	Limited to 8-9 databits. Other configurations of DATABITS in USARTn_FRAME are not possible.
IrDA	Not available. IREN in USARTn_IRCTRL is always 0.

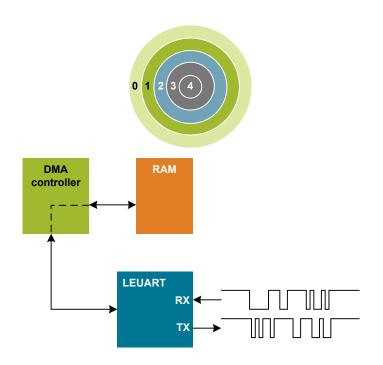

## 18.4 Register Description

The register description of the UART is equivalent to the register description of the USART except the limitations mentioned in Table 18.1 UART Limitations on page 638. See the USART chapter for complete information.

## 18.5 Register Map

The register map of the UART is equivalent to the register map of the USART. See the USART chapter for complete information.

# 19. LEUART - Low Energy Universal Asynchronous Receiver/Transmitter

#### **Quick Facts**

## What?

The LEUART provides full UART communication using a low frequency 32.768 kHz clock, and has special features for communication without CPU intervention.

## Why?

It allows UART communication to be performed in low energy modes, using only a few  $\mu A$  during active communication and only 150 nA when waiting for incoming data.

## How?

A low frequency clock signal allows communication with less energy. Using DMA, the LEUART can transmit and receive data with minimal CPU intervention. Special UART-frames can be configured to help control the data flow, further automating data transmission.

#### 19.1 Introduction

The unique LEUART<sup>TM</sup>, the Low Energy UART, is a UART that allows two-way UART communication on a strict power budget. Only a 32.768 kHz clock is needed to allow UART communication at baud rates up to 9600.

Even when the EFM is in low energy mode EM2 (with most core functionality turned off), the LEUART can wait for an incoming UART frame while having an extremely low energy consumption. When a UART frame is completely received, the CPU can quickly be woken up. Alternatively, multiple frames can be transferred via the Direct Memory Access (DMA) module into RAM memory before waking up the CPU.

Received data can optionally be blocked until a configurable start frame is detected. A signal frame can be configured to generate an interrupt to indicate e.g. the end of a data transmission. The start frame and signal frame can be used in combination for instance to handle higher level communication protocols.

Similarly, data can be transmitted in EM2 either on a frame-by-frame basis with data from the CPU or through use of the DMA.

The LEUART includes all necessary hardware support to make asynchronous serial communication possible with minimum of software intervention and energy consumption.

## 19.2 Features

- · Low energy asynchronous serial communications
- · Full/half duplex communication
- · Separate TX / RX enable
- · Separate double buffered transmit buffer and receive buffer
- · Programmable baud rate, generated as a fractional division of the LFBCLK
  - · Supports baud rates from 300 baud/s to 9600 baud/s
- · Can use a high frequency clock source for even higher baud rates
- Configurable number of data bits: 8 or 9 (plus parity bit, if enabled)
- · Configurable parity: off, even or odd
  - · HW parity bit generation and check
- · Configurable number of stop bits, 1 or 2
- · Capable of sleep-mode wake-up on received frame
  - · Either wake-up on any received byte or
  - · Wake up only on specified start and signal frames
- · Supports transmission and reception in EM0, EM1 and EM2 with
  - · Full DMA support
  - · Specified start-byte can start reception automatically
- IrDA modulator (pulse generator, pulse extender)
- · Multi-processor mode
- · Loopback mode
  - · Half duplex communication
  - · Communication debugging
- · PRS RX input

# 19.3 Functional Description

An overview of the LEUART module is shown in the following figure.

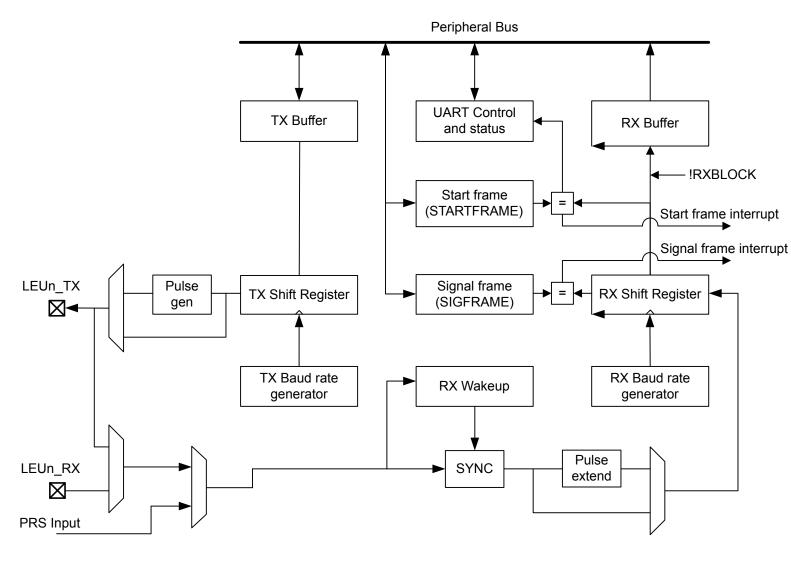

Figure 19.1. LEUART Overview

#### 19.3.1 Frame Format

The frame format used by the LEUART consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. A frame starts with one start-bit (S), where the line is driven low for one bit-period. This signals the start of a frame, and is used for synchronization. Following the start bit are 8 or 9 data bits and an optional parity bit. The data is transmitted with the least significant bit first. Finally, a number of stop-bits, where the line is driven high, end the frame. The frame format is shown in the following figure.

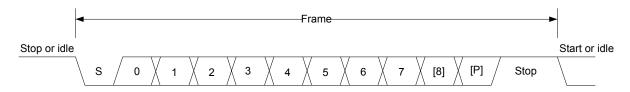

Figure 19.2. LEUART Asynchronous Frame Format

The number of data bits in a frame is set by DATABITS in LEUARTn\_CTRL, and the number of stop-bits is set by STOPBITS in LEUARTn\_CTRL. Whether or not a parity bit should be included, and whether it should be even or odd is defined by PARITY in LEUARTn\_CTRL. For communication to be possible, all parties of an asynchronous transfer must agree on the frame format being used.

The frame format used by the LEUART can be inverted by setting INV in LEUARTn\_CTRL. This affects the entire frame, resulting in a low idle state, a high start-bit, inverted data and parity bits, and low stop-bits. INV should only be changed while the receiver is disabled.

## 19.3.1.1 Parity Bit Calculation and Handling

Hardware automatically inserts parity bits into outgoing frames and checks the parity bits of incoming frames. The possible parity modes are defined in Table 19.1 LEUART Parity Bit on page 642. When even parity is chosen, a parity bit is inserted to make the number of high bits (data + parity) even. If odd parity is chosen, the parity bit makes the total number of high bits odd. When parity bits are disabled, which is the default configuration, the parity bit is omitted.

Description

No parity (default)

Reserved

Table 19.1. LEUART Parity Bit

See 19.3.5.4 Parity Error for more information on parity bit handling.

#### 19.3.2 Clock Source

**PARITY [1:0]** 

00

01

10

11

The LEUART clock source is selected by the LFB bit field the CMU\_LFCLKSEL register. The clock is prescaled by the LEUARTn bit-field in the CMU LFBPRESC0 register and enabled by the LEUARTn bit in the CMU LFBCLKEN0.

Even parity

Odd parity

To use this module, the LE interface clock must be enabled in CMU HFCORECLKENO, in addition to the module clock.

#### 19.3.3 Clock Generation

The LEUART clock defines the transmission and reception data rate. The clock generator employs a fractional clock divider to allow baud rates that are not attainable by integral division of the 32.768 kHz clock that drives the LEUART.

The clock divider used in the LEUART is a 12-bit value, with a 7-bit integral part and a 5-bit fractional part. The baud rate of the LEUART is given by:

$$br = \frac{f_{LEUARTn}}{1 + \frac{LEUARTn\_CLKDIV}{256}}$$

where f<sub>LEUARTn</sub> is the clock frequency supplied to the LEUART. The value of LEUARTn\_CLKDIV thus defines the baud rate of the LEUART. The integral part of the divider is right-aligned in the upper 24 bits of LEUARTn\_CLKDIV and the fractional part is left-aligned in the lower 8 bits. The divider is thus a 256th of LEUARTn\_CLKDIV as seen in the equation.

$$LEUARTn\_CLKDIV = 256 \times \frac{f_{LEUARTn}}{br_{DESIRED} - 1}$$

The following table lists a set of desired baud rates and the closest baud rates reachable by the LEUART with a 32.768 kHz clock source. It also shows the average baud rate error.

LEUARTn CLKDIV LEUARTn\_CLKDIV/256 **Desired baud rate Actual baud rate** Error [%] [baud/s] [baud/s] 300 27704 108.21875 300.0217 0.01 600 13728 53.625 599.8719 -0.021200 6736 26.3125 1199.744 -0.022400 3240 12.65625 2399.487 -0.024800 1488 5.8125 4809.982 0.21

## 19.3.4 Data Transmission

616

9600

Data transmission is initiated by writing data to the transmit buffer using one of the methods described in 19.3.4.1 Transmit Buffer Operation. When the transmission shift register is empty and ready for new data, a frame from the transmit buffer is loaded into the shift register, and if the transmitter is enabled, transmission begins. When the frame has been transmitted, a new frame is loaded into the shift register if available, and transmission continues. If the transmit buffer is empty, the transmitter goes to an idle state, waiting for a new frame to become available. Transmission is enabled through the command register LEUARTn\_CMD by setting TXEN, and disabled by setting TXDIS. When the transmitter is disabled using TXDIS, any ongoing transmission is aborted, and any frame currently being transmitted is discarded. When disabled, the TX output goes to an idle state, which by default is a high value. Whether or not the transmitter is enabled at a given time can be read from TXENS in LEUARTn\_STATUS. After a transmission, when there is no more data in the shift register or transmit buffer, the TXC flag in LEUARTn\_STATUS and the TXC interrupt flag in LEUARTn\_IF are set, signaling that the transmitter is idle. The TXC status flag is cleared when a new byte becomes available for transmission, but the TXC interrupt flag must be cleared by software.

## 19.3.4.1 Transmit Buffer Operation

A frame can be loaded into the transmit buffer by writing to LEUARTn\_TXDATA or LEUARTn\_TXDATAX. Using LEUARTn\_TXDATA allows 8 bits to be written to the buffer. If 9 bit frames are used, the 9th bit will in that case be set to the value of BIT8DV in LEUARTn\_CTRL. To set the 9th bit directly and/or use transmission control, LEUARTn\_TXDATAX must be used. When writing data to the transmit buffer using LEUARTn\_TXDATAX, the 9th bit written to LEUARTn\_TXDATAX overrides the value in BIT8DV, and alone defines the 9th bit that is transmitted if 9-bit frames are used.

If a write is attempted to the transmit buffer when it is not empty, the TXOF interrupt flag in LEUARTn\_IF is set, indicating the overflow. The data already in the buffer is in that case preserved, and no data is written.

In addition to the interrupt flag TXC in LEUARTn\_IF and the status flag TXC in LEUARTn\_STATUS which are set when the transmitter becomes idle, TXBL in LEUARTn\_STATUS and the TXBL interrupt flag in LEUARTn\_IF are used to indicate the level of the transmit buffer. Whenever the transmit buffer becomes empty, these flags are set high. Both the TXBL status flag and the TXBL interrupt flag are cleared automatically when data is written to the transmit buffer.

The transmit buffer, including the TX shift register can be cleared by setting command bit CLEARTX in LEUARTn\_CMD. This will prevent the LEUART from transmitting the data in the buffer and shift register, and will make them available for new data. Any frame currently being transmitted will not be aborted. Transmission of this frame will be completed. An overview of the operation of the transmitter is shown in the following figure.

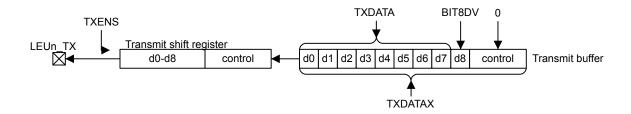

Figure 19.3. LEUART Transmitter Overview

## 19.3.4.2 Frame Transmission Control

The transmission control bits, which can be written using LEUARTn\_TXDATAX, affect the transmission of the written frame. The following options are available:

- Generate break: By setting WBREAK, the output will be held low during the first stop-bit period to generate a framing error. A receiver that supports break detection detects this state, allowing it to be used e.g. for framing of larger data packets. The line is driven high for one baud period before the next frame is transmitted so the next start condition can be identified correctly by the recipient. Continuous breaks lasting longer than an UART frame are thus not supported by the LEUART. GPIO can be used for this. Note that when AUTOTRI in LEUARTn\_CTRL is used, the transmitter is not tristated before the high-bit after the break has been transmitted.
- · Disable transmitter after transmission: If TXDISAT is set, the transmitter is disabled after the frame has been fully transmitted.
- Enable receiver after transmission: If RXENAT is set, the receiver is enabled after the frame has been fully transmitted. It is enabled in time to detect a start-bit directly after the last stop-bit has been transmitted.

The transmission control bits in the LEUART cannot tristate the transmitter. This is performed automatically by hardware however, if AUTOTRI in LEUARTn\_CTRL is set. See 19.3.7 Half Duplex Communication for more information on half duplex operation.

## 19.3.4.3 Jitter in Transmitted Data

Internally the LEUART module uses only the positive edges of the 32.768 kHz clock (LFBCLK) for transmission and reception. Transmitted data will thus have jitter equal to the difference between the optimal data set-up location and the closest positive edge on the 32.768 kHz clock. The jitter in on the location data is set up by the transmitter will thus be no more than half a clock period according to the optimal set-up location. The jitter in the period of a single baud output by the transmitter will never be more than one clock period.

## 19.3.5 Data Reception

Data reception is enabled by setting RXEN in LEUARTn\_CMD. When the receiver is enabled, it actively samples the input looking for a transition from high to low indicating the start baud of a new frame. When a start baud is found, reception of the new frame begins if the receive shift register is empty and ready for new data. When the frame has been received, it is pushed into the receive buffer, making the shift register ready for another frame of data, and the receiver starts looking for another start baud. If the receive buffer is full, the received frame remains in the shift register until more space in the receive buffer is available.

If an incoming frame is detected while both the receive buffer and the receive shift register are full, the data in the receive shift register is overwritten, and the RXOF interrupt flag in LEUARTn\_IF is set to indicate the buffer overflow.

The receiver can be disabled by setting the command bit RXDIS in LEUARTn\_CMD. Any frame currently being received when the receiver is disabled is discarded. Whether or not the receiver is enabled at a given time can be read out from RXENS in LEUARTn\_STATUS.

#### 19.3.5.1 Receive Buffer Operation

When data becomes available in the receive buffer, the RXDATAV flag in LEUARTn\_STATUS and the RXDATAV interrupt flag in LEUARTn\_IF are set. Both the RXDATAV status flag and the RXDATAV interrupt flag are cleared by hardware when data is no longer available, i.e. when data has been read out of the buffer.

Data can be read from receive buffer using either LEUARTn\_RXDATA or LEUARTn\_RXDATAX. LEUARTn\_RXDATA gives access to the 8 least significant bits of the received frame, while LEUARTn\_RXDATAX must be used to get access to the 9th, most significant bit. The latter register also contains status information regarding the frame.

When a frame is read from the receive buffer using LEUARTn\_RXDATA or LEUARTn\_RXDATAX, the frame is removed from the buffer, making room for a new one. If an attempt is done to read more frames from the buffer than what is available, the RXUF interrupt flag in LEUARTn IF is set to signal the underflow, and the data read from the buffer is undefined.

Frames can also be read from the receive buffer without removing the data by using LEUARTn\_RXDATAXP, which gives access to the frame in the buffer including control bits. Data read from this register when the receive buffer is empty is undefined. No underflow interrupt is generated by a read using LEUARTn\_RXDATAXP, i.e. the RXUF interrupt flag is never set as a result of reading from LEUARTn\_RXDATAXP.

An overview of the operation of the receiver is shown in the following figure.

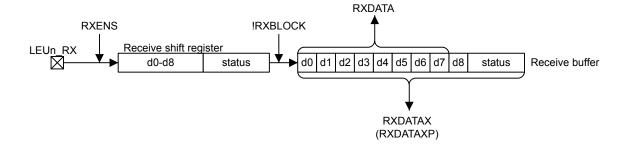

Figure 19.4. LEUART Receiver Overview

## 19.3.5.2 Blocking Incoming Data

When using hardware frame recognition, as detailed in 19.3.5.6 Programmable Start Frame, 19.3.5.7 Programmable Signal Frame, and 19.3.5.8 Multi-Processor Mode, it is necessary to be able to let the receiver sample incoming frames without passing the frames to software by loading them into the receive buffer. This is accomplished by blocking incoming data.

Incoming data is blocked as long as RXBLOCK in LEUARTn\_STATUS is set. When blocked, frames received by the receiver will not be loaded into the receive buffer, and software is not notified by the RXDATAV bit in LEUARTn\_STATUS or the RXDATAV interrupt flag in LEUARTn\_IF at their arrival. For data to be loaded into the receive buffer, RXBLOCK must be cleared in the instant a frame is fully received by the receiver. RXBLOCK is set by setting RXBLOCKEN in LEUARTn\_CMD and disabled by setting RXBLOCKDIS also in LEUARTn\_CMD. There are two exceptions where data is loaded into the receive buffer even when RXBLOCK is set. The first is when an address frame is received when in operating in multi-processor mode as shown in 19.3.5.8 Multi-Processor Mode. The other case is when receiving a start-frame when SFUBRX in LEUARTn\_CTRL is set; see 19.3.5.6 Programmable Start Frame.

Frames received containing framing or parity errors will not result in the FERR and PERR interrupt flags in LEUARTn\_IF being set while RXBLOCK is set. Hardware recognition is not applied to these erroneous frames, and they are silently discarded.

**Note:** If a frame is received while RXBLOCK in LEUARTn\_STATUS is cleared, but stays in the receive shift register because the receive buffer is full, the received frame will be loaded into the receive buffer when space becomes available even if RXBLOCK is set at that time. The overflow interrupt flag RXOF in LEUARTn\_IF will be set if a frame in the receive shift register, waiting to be loaded into the receive buffer is overwritten by an incoming frame even though RXBLOCK is set.

## 19.3.5.3 Data Sampling

The receiver samples each incoming baud as close as possible to the middle of the baud-period. Except for the start-bit, only a single sample is taken of each of the incoming bauds.

The length of a baud-period is given by 1 + LEUARTn\_CLKDIV/256, as a number of 32.768 kHz clock periods. Let the clock cycle where a start-bit is first detected be given the index 0. The optimal sampling point for each baud in the UART frame is then given by the following equation:

$$S_{\text{opt}}(n) = n \times \left(1 + \frac{\text{LEUARTn\_CLKDIV}}{256}\right) + \frac{\text{CLKDIV}}{512}$$

where n is the bit-index.

Since samples are only done on the positive edges of the 32.768 kHz clock, the actual samples are performed on the closest positive edge, i.e. the edge given by the following equation:

$$S(n) = floor \left( n \times \left( 1 + \frac{LEUARTn\_CLKDIV}{256} \right) + \frac{LEUARTn\_CLKDIV}{512} \right)$$

The sampling location will thus have jitter according to difference between  $S_{opt}$  and S. The start-bit is found at n=0, then follows the data bits, any parity bit, and the stop bits.

If the value of the start-bit is found to be high, then the start-bit is discarded, and the receiver waits for a new start-bit.

## 19.3.5.4 Parity Error

When the parity bit is enabled, a parity check is automatically performed on incoming frames. When a parity error is detected in a frame, the data parity error bit PERR in the frame is set, as well as the interrupt flag PERR. Frames with parity errors are loaded into the receive buffer like regular frames.

PERR can be accessed by reading the frame from the receive buffer using the LEUARTn\_RXDATAX register.

# 19.3.5.5 Framing Error and Break Detection

A framing error is the result of a received frame where the stop bit was sampled to a value of 0. This can be the result of noise and baud rate errors, but can also be the result of a break generated by the transmitter on purpose.

When a framing error is detected, the framing error bit FERR in the received frame is set. The interrupt flag FERR in LEUARTn\_IF is also set. Frames with framing errors are loaded into the receive buffer like regular frames.

FERR can be accessed by reading the frame from the receive buffer using the LEUARTn\_RXDATAX or LEUARTn\_RXDATAXP registers.

## 19.3.5.6 Programmable Start Frame

The LEUART can be configured to start receiving data when a special start frame is detected on the input. This can be useful when operating in low energy modes, allowing other devices to gain the attention of the LEUART by transmitting a given frame.

When SFUBRX in LEUARTn\_CTRL is set, an incoming frame matching the frame defined in LEUARTn\_STARTFRAME will result in RXBLOCK in LEUARTn\_STATUS being cleared. This can be used to enable reception when a specified start frame is detected. If the receiver is enabled and blocked, i.e. RXENS and RXBLOCK in LEUARTn\_STATUS are set, the receiver will receive all incoming frames, but unless an incoming frame is a start frame it will be discarded and not loaded into the receive buffer. When a start frame is detected, the block is cleared, and frames received from that point, including the start frame, are loaded into the receive buffer.

An incoming start frame results in the STARTF interrupt flag in LEUARTn\_IF being set, regardless of the value of SFUBRX in LEUARTn CTRL. This allows an interrupt to be made when the start frame is detected.

When 8 data-bit frame formats are used, only the 8 least significant bits of LEUARTn\_STARTFRAME are compared to incoming frames. The full length of LEUARTn STARTFRAME is used when operating with frames consisting of 9 data bits.

**Note:** The receiver must be enabled for start frames to be detected. In addition, a start frame with a parity error or framing error is not detected as a start frame.

## 19.3.5.7 Programmable Signal Frame

As well as the configurable start frame, a special signal frame can be specified. When a frame matching the frame defined in LEUARTn\_SIGFRAME is detected by the receiver, the SIGF interrupt flag in LEUARTn\_IF is set. As for start frame detection, the receiver must be enabled for signal frames to be detected.

One use of the programmable signal frame is to signal the end of a multi-frame message transmitted to the LEUART. An interrupt will then be triggered when the packet has been completely received, allowing software to process it. Used in conjunction with the programmable start frame and DMA, this makes it possible for the LEUART to automatically begin the reception of a packet on a specified start frame, load the entire packet into memory, and give an interrupt when reception of a packet has completed. The device can thus wait for data packets in EM2, and only be woken up when a packet has been completely received.

A signal frame with a parity error or framing error is not detected as a signal frame.

#### 19.3.5.8 Multi-Processor Mode

To simplify communication between multiple processors and maintain compatibility with the USART, the LEUART supports a multi-processor mode. In this mode the 9th data bit in each frame is used to indicate whether the content of the remaining 8 bits is data or an address.

When multi-processor mode is enabled, an incoming 9-bit frame with the 9th bit equal to the value of MPAB in LEUARTn\_CTRL is identified as an address frame. When an address frame is detected, the MPAF interrupt flag in LEUARTn\_IF is set, and the address frame is loaded into the receive register. This happens regardless of the value of RXBLOCK in LEUARTn\_STATUS.

Multi-processor mode is enabled by setting MPM in LEUARTn\_CTRL. The mode can be used in buses with multiple slaves, allowing the slaves to be addressed using the special address frames. An addressed slave, which was previously blocking reception using RXBLOCK, would then unblock reception, receive a message from the bus master, and then block reception again, waiting for the next message. See the USART for a more detailed example.

**Note:** The programmable start frame functionality can be used for automatic address matching, enabling reception on a correctly configured incoming frame.

An address frame with a parity error or a framing error is not detected as an address frame.

## 19.3.6 Loopback

The LEUART receiver samples LEUn\_RX by default, and the transmitter drives LEUn\_TX by default. This is not the only configuration however. When LOOPBK in LEUARTn\_CTRL is set, the receiver is connected to the LEUn\_TX pin as shown in the following figure. This is useful for debugging, as the LEUART can receive the data it transmits, but it is also used to allow the LEUART to read and write to the same pin, which is required for some half duplex communication modes. In this mode, the LEUn\_TX pin must be enabled as an output in the GPIO.

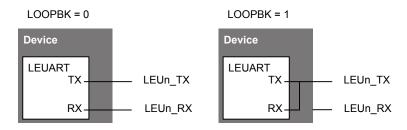

Figure 19.5. LEUART Local Loopback

## 19.3.7 Half Duplex Communication

When doing full duplex communication, two data links are provided, making it possible for data to be sent and received at the same time. In half duplex mode, data is only sent in one direction at a time. There are several possible half duplex setups, as described in the following sections.

## 19.3.7.1 Single Data-Link

In this setup, the LEUART both receives and transmits data on the same pin. This is enabled by setting LOOPBK in LEUARTn\_CTRL, which connects the receiver to the transmitter output. Because they are both connected to the same line, it is important that the LEUART transmitter does not drive the line when receiving data, as this would corrupt the data on the line.

When communicating over a single data-link, the transmitter must thus be tristated whenever not transmitting data. If AUTOTRI in LEUARTn\_CTRL is set, the LEUART automatically tristates LEUn\_TX whenever the transmitter is inactive. It is then the responsibility of the software protocol to make sure the transmitter is not transmitting data whenever incoming data is expected.

The transmitter can also be tristated from software by configuring the GPIO pin as an input and disabling the LEUART output on LEUn\_TX.

**Note:** Another way to tristate the transmitter is to enable wired-and or wired-or mode in GPIO. For wired-and mode, outputting a 1 will be the same as tristating the output, and for wired-or mode, outputting a 0 will be the same as tristating the output. This can only be done on buses with a pull-up or pull-down resistor respectively.

## 19.3.7.2 Single Data-Link with External Driver

Some communication schemes, such as RS-485 rely on an external driver. Here, the driver has an extra input which enables it, and instead of Tristating the transmitter when receiving data, the external driver must be disabled. The USART has hardware support for automatically turning the driver on and off. When using the LEUART in such a setup, the driver must be controlled by a GPIO. The following figure shows an example configuration using an external driver.

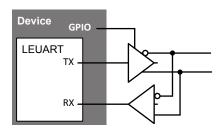

Figure 19.6. LEUART Half Duplex Communication with External Driver

#### 19.3.7.3 Two Data-Links

Some limited devices only support half duplex communication even though two data links are available. In this case software is responsible for making sure data is not transmitted when incoming data is expected.

#### 19.3.8 Transmission Delay

By configuring TXDELAY in LEUARTn\_CTRL, the transmitter can be forced to wait a number of bit periods from it is ready to transmit data, to it actually transmits the data. This delay is only applied to the first frame transmitted after the transmitter has been idle. When transmitting frames back-to-back the delay is not introduced between the transmitted frames.

This is useful on half duplex buses, because the receiver always returns received frames to software during the first stop-bit. The bus may still be driven for up to 3 baud periods, depending on the current frame format. Using the transmission delay, a transmission can be started when a frame is received, and it is possible to make sure that the transmitter does not begin driving the output before the frame on the bus is completely transmitted.

### 19.3.9 PRS RX Input

The LEUART can be configured to receive data directly from the PRS channel by setting RX\_PRS in LEUARTn\_INPUT. The PRS channel used can be selected using RX\_PRS\_SEL in LEUARTn\_INPUT.

### 19.3.10 DMA Support

The LEUART has full DMA support in energy modes EM0 – EM2. The DMA controller can write to the transmit buffer using the registers LEUARTn\_TXDATA and LEUARTn\_TXDATAX, and it can read from receive buffer using the registers LEUARTn\_RXDATA and LEUARTn\_RXDATAX. This enables single byte transfers and 9 bit data + control/status bits transfers both to and from the LEUART. The DMA will start up the HFRCO and run from this when it is waken by the LEUART in EM2. The HFRCO is disabled once the transaction is done.

A request for the DMA controller to read from the receive buffer can come from one of the following sources:

· Receive buffer full

A write request can come from one of the following sources:

- · Transmit buffer and shift register empty. No data to send.
- · Transmit buffer empty

In some cases, it may be sensible to temporarily stop DMA access to the LEUART when a parity or framing error has occurred. This is enabled by setting ERRSDMA in LEUARTn\_CTRL. When this bit is set, the DMA controller will not get requests from the receive buffer if a framing error or parity error is detected in the received byte. The ERRSDMA bit applies only to the RX DMA.

When operating in EM2, the DMA controller must be powered up in order to perform the transfer. This is automatically performed for read operations if RXDMAWU in LEUARTn\_CTRL is set and for write operations if TXDMAWU in LEUARTn\_CTRL is set. To make sure the DMA controller still transfers bits to and from the LEUART in low energy modes, these bits must thus be configured accordingly.

**Note:** When RXDMAWU or TXDMAWU is set, the system will not be able to go to EM2/EM3 before all related LEUART DMA requests have been processed. This means that if RXDMAWU is set and the LEUART receives a frame, the system will not be able to go to EM2/EM3 before the frame has been read from the LEUART. In order for the system to go to EM2 during the last byte transmission, LEUART\_CTRL\_TXDMAWU must be cleared in the DMA interrupt service routine. This is because TXBL will be high during that last byte transfer.

#### 19.3.11 Pulse Generator / Pulse Extender

The LEUART has an optional pulse generator for the transmitter output, and a pulse extender on the receiver input. These are enabled by setting PULSEEN in LEUARTn\_PULSECTRL, and with INV in LEUARTn\_CTRL set, they will change the output/input format of the LEUART from NRZ to RZI as shown in the following figure.

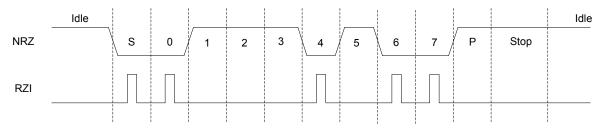

Figure 19.7. LEUART - NRZ vs. RZI

If PULSEEN in LEUARTn\_PULSECTRL is set while INV in LEUARTn\_CTRL is cleared, the output waveform will like RZI shown in the previous figure, only inverted.

The width of the pulses from the pulse generator can be configured using PULSEW in LEUARTn\_PULSECTRL. The generated pulse width is PULSEW + 1 cycles of the 32.768 kHz clock, which makes pulse width from 31.25 µs to 500 µs possible.

Since the incoming signal is only sampled on positive clock edges, the width of the incoming pulses must be at least two 32.768 kHz clock periods wide for reliable detection by the LEUART receiver. They must also be shorter than half a UART baud period.

At 2400 baud/s or lower, the pulse generator is able to generate RZI pulses compatible with the IrDA physical layer specification. The external IrDA device must generate pulses of sufficient length for successful two-way communication.

### 19.3.11.1 Interrupts

The interrupts generated by the LEUART are combined into one interrupt vector. If LEUART interrupts are enabled, an interrupt will be made if one or more of the interrupt flags in LEUART IF and their corresponding bits in LEUART IEN are set.

### 19.3.12 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to 5.2.4 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals.

D:4	N			Description
Bit	Name	Reset	Access	Description
10	MPAB	0	RW	Multi-Processor Address-Bit
		e of the multi-proc nulti-processor add		s bit. An incoming frame with its 9th bit equal to the value of this bit marks
9	MPM	0	RW	Multi-Processor Mode
	Set to enable mu	ulti-processor mod	e.	
	Value			Description
	0			The 9th bit of incoming frames have no special function
	1			An incoming frame with the 9th bit equal to MPAB will be loaded into the receive buffer regardless of RXBLOCK and will result in the MPAB interrupt flag being set
8	SFUBRX	0	RW	Start-Frame UnBlock RX
	Clears RXBLOC	K when the start-f	rame is found	in the incoming data. The start-frame is loaded into the receive buffer.
	Value			Description
	0			Detected start-frames have no effect on RXBLOCK
	1			When a start-frame is detected, RXBLOCK is cleared and the start-frame is loaded into the receive buffer
7	LOOPBK	0	RW	Loopback Enable
	Set to connect re	eceiver to LEUn_T	X instead of L	.EUn_RX.
	Value			Description
	0			The receiver is connected to and receives data from LEUn_RX
	1			The receiver is connected to and receives data from LEUn_TX
6	ERRSDMA	0	RW	Clear RX DMA On Error
	When set,RX DN	MA requests will be	e cleared on fi	raming and parity errors.
	Value			Description
	0			Framing and parity errors have no effect on DMA requests from the LEUART
	1			RX DMA requests from the LEUART are disabled if a framing error or parity error occurs.
5	INV	0	RW	Invert Input And Output
	Set to invert the	output on LEUn_T	X and input o	on LEUn_RX.
	Value			Description
	0			A high value on the input/output is 1, and a low value is 0.
	1			A low value on the input/output is 1, and a high value is 0.
4	STOPBITS	0	RW	Stop-Bit Mode
	Determines the resent.	number of stop-bit	s used. Only ι	used when transmitting data. The receiver only verifies that one stop bit is
	Value	Mode		Description
				·

Bit	Name	Reset	Access	Description
	0	ONE		One stop-bit is transmitted with every frame
	1	TWO		Two stop-bits are transmitted with every frame
3:2	PARITY	0x0	RW	Parity-Bit Mode
	Determines whether p	parity bits are en	abled, and	whether even or odd parity should be used.
	Value	Mode		Description
	0	NONE		Parity bits are not used
	2	EVEN		Even parity are used. Parity bits are automatically generated and checked by hardware.
	3	ODD		Odd parity is used. Parity bits are automatically generated and checked by hardware.
1	DATABITS	0	RW	Data-Bit Mode
	This register sets the	number of data	bits.	
	Value	Mode		Description
	0	EIGHT		Each frame contains 8 data bits
	1	NINE		Each frame contains 9 data bits
0	AUTOTRI	0	RW	Automatic Transmitter Tristate
	When set, LEUn_TX	is tristated when	ever the tr	ansmitter is inactive.
	Value			Description
	0			LEUn_TX is held high when the transmitter is inactive. INV inverts the inactive state.
	1			LEUn_TX is tristated when the transmitter is inactive

### 20. TIMER - Timer/Counter

#### **Quick Facts**

#### What?

The TIMER (Timer/Counter) keeps track of timing and counts events, generates output waveforms and triggers timed actions in other peripherals.

### Why?

Most applications have activities that need to be timed accurately with as little CPU intervention and energy consumption as possible.

### How?

The flexible 16-bit TIMER can be configured to provide PWM waveforms with optional dead-time insertion for e.g. motor control, or work as a frequency generator. The Timer can also count events and control other peripherals through the PRS, which offloads the CPU and reduce energy consumption.

#### 20.1 Introduction

The 16-bit general purpose Timer has 3 compare/capture channels for input capture and compare/Pulse- Width Modulation (PWM) output. TIMER0 also includes a Dead-Time Insertion module suitable for motor control applications.

#### 20.2 Features

- · 16-bit auto reload up/down counter
  - · Dedicated 16-bit reload register which serves as counter maximum
- 3 Compare/Capture channels
  - · Individual configurable as either input capture or output compare/PWM
- · Multiple Counter modes
  - Count up
  - · Count down
  - · Count up/down
  - · Quadrature Decoder
  - · Direction and count from external pins
- · 2x Count Mode
- · Counter control from PRS or external pin
  - Start
  - Stop
  - · Reload and start
- · Inter-Timer connection
- Allows 32-bit counter mode
  - · Start/stop synchronization between several Timers
- · Input Capture
  - · Period measurement
  - · Pulse width measurement
  - · Two capture registers for each capture channel
    - · Capture on either positive or negative edge
    - · Capture on both edges
  - · Optional digital noise filtering on capture inputs
- · Output Compare
  - · Compare output toggle/pulse on compare match
  - · Immediate update of compare registers
- PWM
  - · Up-count PWM
  - · Up/down-count PWM
  - Predictable initial PWM output state (configured by SW)
  - Buffered compare register to ensure glitch-free update of compare values
- Clock sources
  - HFPERCLK<sub>TIMERn</sub>
    - · 10-bit Prescaler
  - · External pin
  - Peripheral Reflex System
- · Debug mode
  - · Configurable to either run or stop when processor is stopped (break)
- · Interrupts, PRS output and/or DMA request
  - · Underflow
  - · Overflow
  - · Compare/Capture event
- Dead-Time Insertion Unit (TIMER0 only)
  - · Complementary PWM outputs with programmable dead-time
    - Dead-time is specified independently for rising and falling edge
      - · 10-bit prescaler
      - · 6-bit time value
    - · Outputs have configurable polarity
    - · Outputs can be set inactive individually by software.

- · Configurable action on fault
  - · Set outputs inactive
  - · Clear output
  - · Tristate output
- · Individual fault sources
  - · One or two PRS signals
  - · Debugger
    - · Support for automatic restart
  - · Core lockup
- · Configuration lock

#### 20.3 Functional Description

An overview of the TIMER module is shown in the following figure. The Timer module consists of a 16 bit up/down counter with 3 Compare/Capture channels connected to pins TIMn CC0, TIMn CC1, and TIMn CC2.

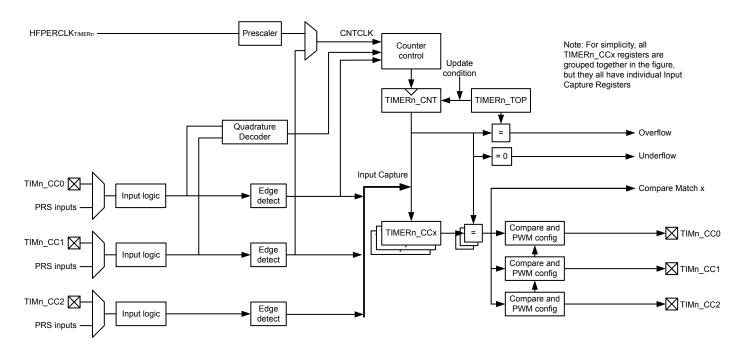

Figure 20.1. TIMER Block Overview

#### 20.3.1 Counter Modes

The Timer consists of a counter that can be configured to the following modes:

- 1. Up-count: Counter counts up until it reaches the value in TIMERn TOP, where it is reset to 0 before counting up again.
- 2. Down-count: The counter starts at the value in TIMERn\_TOP and counts down. When it reaches 0, it is reloaded with the value in TIMERn\_TOP.
- 3. Up/Down-count: The counter starts at 0 and counts up. When it reaches the value in TIMERn\_TOP, it counts down until it reaches 0 and starts counting up again.
- 4. Quadrature Decoder: Two input channels where one determines the count direction, while the other pin triggers a clock event.

In addition, to the TIMER modes listed above, the TIMER also supports a 2x Count Mode. In this mode the counter increments/decrements by 2. The 2x Count Mode intended use is to generate 2x PWM frequency when the Compare/Capture channel is put in PWM mode. The 2x Count Mode can be enabled by setting the X2CNT bitfield in the TIMERn\_CTRL register.

The counter value can be read or written by software at any time by accessing the CNT field in TIMERn\_CNT.

#### 20.3.1.1 Events

Overflow is set when the counter value shifts from TIMERn\_TOP to the next value when counting up. In up-count mode the next value is 0. In up/down-count mode, the next value is TIMERn\_TOP-1.

Underflow is set when the counter value shifts from 0 to the next value when counting down. In downcount mode, the next value is TIMERn TOP. In up/down-count mode the next value is 1.

Update event is set on overflow in up-count mode and on underflow in down-count or up/down count mode. This event is used to time updates of buffered values.

#### 20.3.1.2 Operation

The following figure shows the hardware Timer/Counter control. Software can start or stop the counter by writing a 1 to the START or STOP bits in TIMERn\_CMD. The counter value (CNT in TIMERn\_CNT) can always be written by software to any 16-bit value.

It is also possible to control the counter through either an external pin or PRS input. This is done through the input logic for the Compare/Capture Channel 0. The Timer/Counter allows individual actions (start, stop, reload) to be taken for rising and falling input edges. This is configured in the RISEA and FALLA fields in TIMERn\_CTRL. The reload value is 0 in up-count and up/down-count mode and TOP in downcount mode.

The RUNNING bit in TIMERn\_STATUS indicates if the Timer is running or not. If the SYNC bit in TIMERn\_CTRL is set, the Timer is started/stopped/reloaded (external pin or PRS) when any of the other timers are started/stopped/reloaded.

The DIR bit in TIMERn\_STATUS indicates the counting direction of the Timer at any given time. The counter value can be read or written by software through the CNT field in TIMERn\_CNT. In Up/Down- Count mode the count direction will be set to up if the CNT value is written by software.

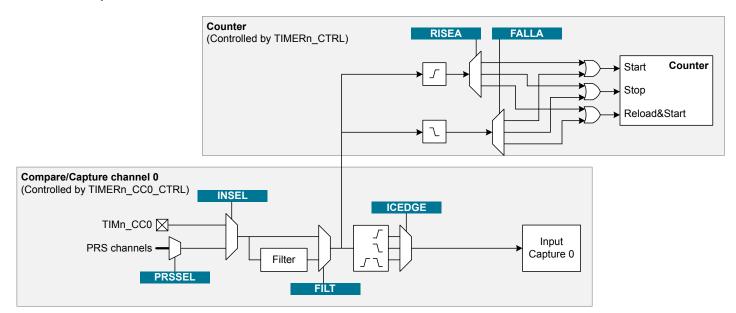

Figure 20.2. TIMER Hardware Timer/Counter Control

#### 20.3.1.3 Clock Source

The counter can be clocked from several sources, which are all synchronized with the peripheral clock (HFPERCLK). See the following figure.

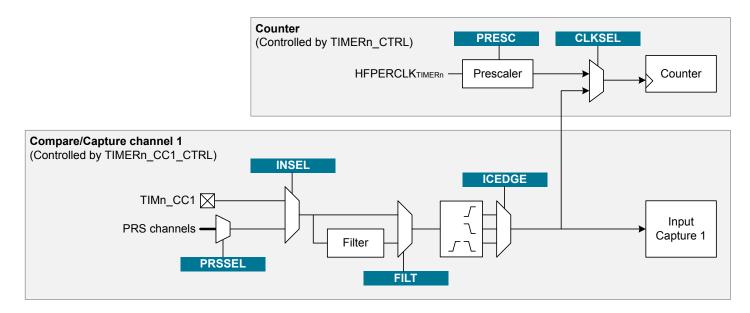

Figure 20.3. TIMER Clock Selection

#### 20.3.1.3.1 Peripheral Clock (HFPERCLK)

The peripheral clock (HFPERCLK) can be used as a source with a configurable prescale factor of 2^PRESC, where PRESC is an integer between 0 and 10, which is set in PRESC in TIMERn\_CTRL. However, if 2x Count Mode is enabled and the Compare/Capture channels are put in PWM mode, the CC output is updated on both clock edges so prescaling the peripheral clock will result in incorrect result. The prescaler is stopped and reset when the timer is stopped.

### 20.3.1.3.2 Compare/Capture Channel 1 Input

The Timer can also be clocked by positive and/or negative edges on the Compare/Capture channel 1 input. This input can either come from the TIMn\_CC1 pin or one of the PRS channels. The input signal must not have a higher frequency than f<sub>HFPERCLK</sub>/3 when running from a pin input or a PRS input with FILT enabled in TIMERn\_CCx\_CTRL. When running from PRS without FILT, the frequency can be as high as f<sub>HFPERCLK</sub>. Note that when clocking the Timer from the same pulse that triggers a start (through RISEA/FALLA in TIMERn\_CTRL), the starting pulse will not update the Counter Value.

### 20.3.1.3.3 Underflow/Overflow from Neighboring Timer

All Timers are linked together (see the following figure), allowing timers to count on overflow/underflow from the lower numbered neighbouring timers to form a 32-bit or 48-bit timer. Note that all timers must be set to same count direction and less significant timer(s) can only be set to count up or down.

Figure 20.4. TIMER Connections

### 20.3.1.4 One-Shot Mode

By default, the counter counts continuously until it is stopped. If the OSMEN bit is set in the TIMERn\_CTRL register, however, the counter is disabled by hardware on the first update event. Note that when the counter is running with CC1 as clock source (0b01 in CLKSEL in TIMERn\_CTRL) and OSMEN is set, a CC1 capture event will not take place on the update event (CC1 rising edge) that stops the Timer.

### 20.3.1.5 Top Value Buffer

The TIMERn\_TOP register can be altered either by writing it directly or by writing to the TIMER\_TOPB (buffer) register. When writing to the buffer register the TIMERn\_TOPB register will be written to TIMERn\_TOP on the next update event. Buffering ensures that the TOP value is not set below the actual count value. The TOPBV flag in TIMERn\_STATUS indicates whether the TIMERn\_TOPB register contains data that have not yet been written to the TIMERn\_TOP register (see the following figure).

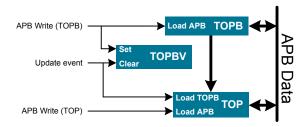

Figure 20.5. TIMER TOP Value Update Functionality

#### 20.3.1.6 Quadrature Decoder

Quadrature Decoding mode is used to track motion and determine both rotation direction and position. The Quadrature Decoder uses two input channels that are 90 degrees out of phase (see the following figure).

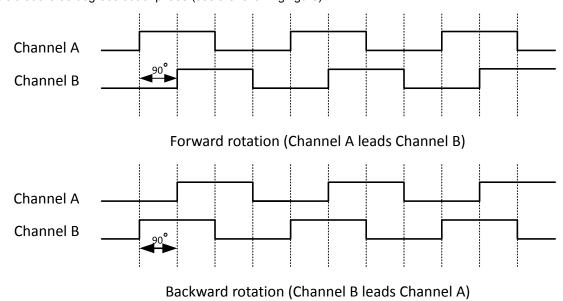

Figure 20.6. TIMER Quadrature Encoded Inputs

In the Timer these inputs are tapped from the Compare/Capture channel 0 (Channel A) and 1 (Channel B) inputs before edge detection. The Timer/Counter then increments or decrements the counter, based on the phase relation between the two inputs. The Quadrature Decoder Mode supports two channels, but if a third channel (Z-terminal) is available, this can be connected to an external interrupt and trigger a counter reset from the interrupt service routine. By connecting a periodic signal from another timer as input capture on Compare/Capture Channel 2, it is also possible to calculate speed and acceleration.

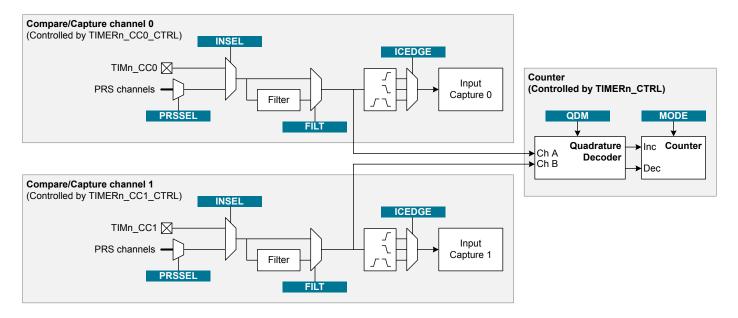

Figure 20.7. TIMER Quadrature Decoder Configuration

The Quadrature Decoder can be set in either X2 or X4 mode, which is configured in the QDM bit in TIMERn\_CTRL. See the previous figure.

### 20.3.1.6.1 X2 Decoding Mode

In X2 Decoding mode, the counter increments or decrements on every edge of Channel A, see the following figure and table.

Table 20.1. TIMER Counter Response in X2 Decoding Mode

Channel B	Channel A							
	Rising	Falling						
0	Increment	Decrement						
1	Decrement	Increment						

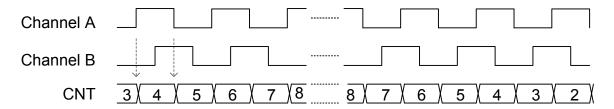

Figure 20.8. TIMER X2 Decoding Mode

### 20.3.1.6.2 X4 Decoding Mode

In X4 Decoding mode, the counter increments or decrements on every edge of Channel A and Channel B, see the following table and figure.

Table 20.2. TIMER Counter Response in X4 Decoding Mode

Opposite Channel	Channel A		Channel B						
	Rising	Falling	Rising	Falling					
Channel A = 0			Decrement	Increment					
Channel A = 1			Increment	Decrement					
Channel B = 0	Increment	Decrement							
Channel B = 1	Decrement	Increment							

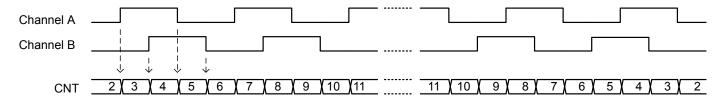

Figure 20.9. TIMER X4 Decoding Mode

### 20.3.1.6.3 TIMER Rotational Position

To calculate a position, the following equation can be used.

$$pos^{\circ} = (CNT/X \times N) \times 360^{\circ}$$

where X = Encoding type and N = Number of pulses per revolution.

#### 20.3.2 Compare/Capture Channels

The Timer contains 3 Compare/Capture channels, which can be configured in the following modes:

- 1. Input Capture
- 2. Output Compare
- 3. PWM

### 20.3.2.1 Input Pin Logic

Each Compare/Capture channel can be configured as an input source for the Capture Unit or as external clock source for the Timer (see the following figure). Compare/Capture channels 0 and 1 are the inputs for the Quadrature Decoder Mode. The input channel can be filtered before it is used, which requires the input to remain stable for 5 cycles in a row before the input is propagated to the output.

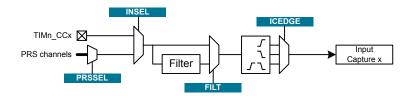

Figure 20.10. TIMER Input Pin Logic

#### 20.3.2.2 Compare/Capture Registers

The Compare/Capture channel registers are prefixed with TIMERn\_CCx\_, where the x stands for the channel number. Since the Compare/Capture channels serve three functions (input capture, compare, PWM), the behavior of the Compare/Capture registers (TIMERn CCx CCV) and buffer registers (TIMERn CCx CCVB) change depending on the mode the channel is set in.

#### 20.3.2.2.1 Input Capture Mode

When running in Input Capture mode, TIMERn\_CCx\_CCV and TIMERn\_CCx\_CCVB form a FIFO buffer, and new capture values are added on a capture event, see the following figure. The first capture can always be read from TIMERn\_CCx\_CCV, and reading this address will load the next capture value into TIMERn\_CCx\_CCV from TIMERn\_CCx\_CCVB if it contains valid data. The CC value can be read without altering the FIFO contents by reading TIMERn\_CCx\_CCVP. TIMERn\_CCx\_CCVB can also be read without altering the FIFO contents. The ICV flag in TIMERn\_STATUS indicates if there is a valid unread capture in TIMERn\_CCx\_CCV.

In case a capture is triggered while both CCV and CCVB contain unread capture values, the buffer overflow interrupt flag (ICBOF in TIMERn\_IF) will be set. New capture values will on overflow overwrite the value in TIMERn\_CCx\_CCVB.

Note: In input capture mode, the timer will only trigger interrupts when it is running

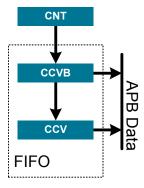

Figure 20.11. TIMER Input Capture Buffer Functionality

#### 20.3.2.2.2 Compare and PWM Mode

When running in Output Compare or PWM mode, the value in TIMERn\_CCx\_CCV will be compared against the count value. In Compare mode the output can be configured to toggle, clear or set on compare match, overflow and underflow through the CMOA, COFOA and CUFOA fields in TIMERn\_CCx\_CTRL. TIMERn\_CCx\_CCV can be accessed directly or through the buffer register TIMERn\_CCx\_CCVB, see the following figure. When writing to the buffer register, the value in TIMERn\_CCx\_CCVB will be written to TIMERn\_CCx\_CCV on the next update event. This functionality ensures glitch free PWM outputs. The CCVBV flag in TIMERn\_STATUS indicates whether the TIMERn\_CCx\_CCVB register contains data that have not yet been written to the TIMERn\_CCx\_CCV register. Note that when writing 0 to TIMERn\_CCx\_CCVB the CCV value is updated when the timer counts from 0 to 1. Thus, the compare match for the next period will not happen until the timer reaches 0 again on the way down.

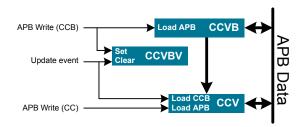

Figure 20.12. TIMER Output Compare/PWM Buffer Functionality

### 20.3.2.3 Input Capture

In Input Capture Mode, the counter value (TIMERn\_CNT) can be captured in the Compare/Capture Register (TIMERn\_CCx\_CCV), see the following figure. In this mode, TIMERn\_CCx\_CCV is read-only. Together with the Compare/Capture Buffer Register (TIMERn\_CCx\_CCVB) the TIMERn\_CCx\_CCV form a double-buffered capture registers allowing two subsequent capture events to take place before a read-out is required. The CCPOL bits in TIMERn\_STATUS indicate the polarity the edge that triggered the capture in TIMERn\_CCx\_CCV.

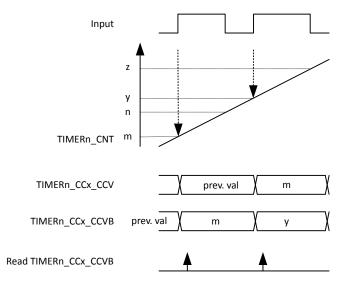

Figure 20.13. TIMER Input Capture

### 20.3.2.3.1 Period/Pulse-Width Capture

Period and/or pulse-width capture can be achieved by setting the RISEA field in TIMERn\_CTRL to Clear&Start, and select the wanted input from either external pin or PRS, see the following figure. For period capture, the Compare/Capture Channel should then be set to input capture on a rising edge of the same input signal. To capture a the width of a high pulse, the Compare/Capture Channel should be set to capture on a falling edge of the input signal. To start the measuring period on either a falling edge or measure the low pulse-width of a signal, opposite polarities should be chosen.

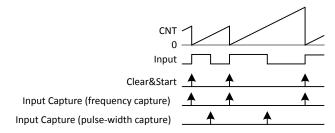

Figure 20.14. TIMER Period and/or Pulse Width Capture

### 20.3.2.4 Compare

Each Compare/Capture channel contains a comparator which outputs a compare match if the contents of TIMERn\_CCx\_CCV matches the counter value, see the following figure. In compare mode, each compare channel can be configured to either set, clear or toggle the output on an event (compare match, overflow or underflow). The output from each channel is represented as an alternative function on the port it is connected to, which needs to be enabled for the CC outputs to propagate to the pins.

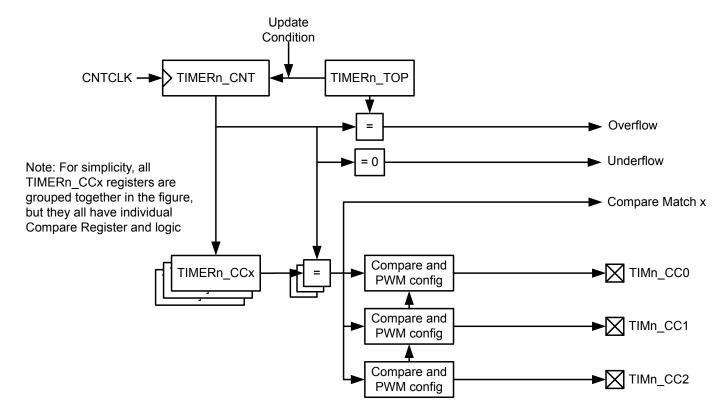

Figure 20.15. TIMER Block Diagram Showing Comparison Functionality

If occurring in the same cycle, match action will have priority over overflow or underflow action.

The input selected (through PRSSEL, INSEL and FILTSEL in TIMERn\_CCx\_CTRL) for the CC channel will also be sampled on compare match and the result is found in the CCPOL bits in TIMERn\_STATUS. It is also possible to configure the CCPOL to always track the inputs by setting ATI in TIMERn\_CTRL.

The COIST bit in TIMERn\_CCx\_CTRL is the initial state of the compare/PWM output. The COIST bit can also be used as an initial value to the compare outputs on a reload-start when RSSCOIST is set in TIMERn\_CTRL. Also the resulting output can be inverted by setting OUTINV in TIMERn\_CCx\_CTRL. It is recommended to turn off the CC channel before configuring the output state to avoid any pulses on the output. The CC channel can be turned off by setting MODE to OFF in TIMER\_CCx\_CTRL.

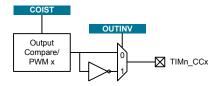

Figure 20.16. TIMER Output Logic

### 20.3.2.4.1 Frequency Generation (FRG)

Frequency generation (see the following figure) can be achieved in compare mode by:

- · Setting the counter in up-count mode
- · Enabling buffering of the TOP value.
- · Setting the CC channels overflow action to toggle

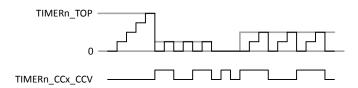

Figure 20.17. TIMER Up-Count Frequency Generation

The output frequency is given by the following equation.

$$f_{\text{FRG}} = \frac{f_{\text{HFPERCLK}}}{2^{(\text{PRESC+1})} \times (\text{TOP} + 1) \times 2}$$

### 20.3.2.5 Pulse-Width Modulation (PWM)

In PWM mode, TIMERn\_CCx\_CCV is buffered to avoid glitches in the output. The settings in the Compare Output Action configuration bits are ignored in PWM mode and PWM generation is only supported for up-count and up/down-count mode.

### 20.3.2.6 Up-Count (Single-Slope) PWM

If the counter is set to up-count and the Compare/Capture channel is put in PWM mode, single slope PWM output will be generated (see the following figure). In up-count mode the PWM period is TOP +1 cycles and the PWM output will be high for a number of cycles equal to TIMERn\_CCx\_CCV. This means that a constant high output is achieved by setting TIMER\_CCx to TOP+1 or higher. The PWM resolution (in bits) is then given by the following equation.

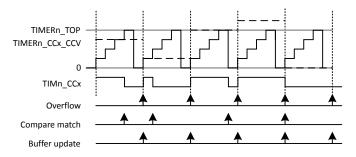

Figure 20.18. TIMER Up-Count PWM Generation

$$R_{\text{PWM}_{\text{up}}} = \frac{\log(\text{TOP} + 1)}{\log(2)}$$

The PWM frequency is given by the following equation:

$$f_{\text{PWM}_{\text{up/down}}} = \frac{f_{\text{HFPERCLK}}}{2^{\text{PRESC}} \times (\text{TOP} + 1)}$$

The high duty cycle is given by the following equation:

$$DS_{up} = CCVx/TOP$$

#### 20.3.2.6.1 2x Count Mode

When the Timer is set in 2x mode, the TIMER will count up by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in the figure below.

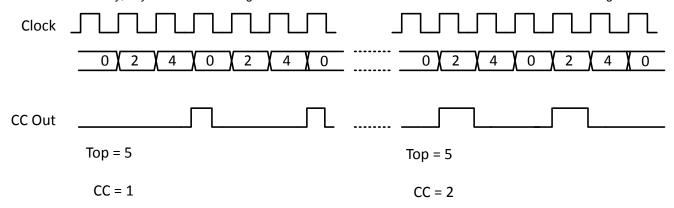

Figure 20.19. TIMER CC Out in 2x Mode

The mode is enabled by setting the X2CNT field in TIMERn\_CTRL register. The intended use of the 2x mode is to generate 2x PWM frequency when the Compare/Capture channel is put in PWM mode. Since the PWM output is updated on both edges of the clock, frequency prescaling will result in incorrect result in this mode. The PWM resolution (in bits) is then given by the following equation.

$$R_{\text{PWM}_{2\text{xmode}}} = \frac{\log(\text{TOP}/2 + 1)}{\log(2)}$$

The PWM frequency is given by the following equation:

$$f_{\text{PWM}_{2\text{xmode}}} = 2 \times \frac{f_{\text{HFPERCLK}}}{\text{floor}(\text{TOP}/2)} + 1$$

The high duty cycle is given by the following equation:

$$DS_{2xmode} = CCVx/TOP$$

#### 20.3.2.7 Up/Down-Count (Dual-Slope) PWM

If the counter is set to up-down count and the Compare/Capture channel is put in PWM mode, dual slope PWM output will be generated by the following figure. The resolution (in bits) is given by the following equation.

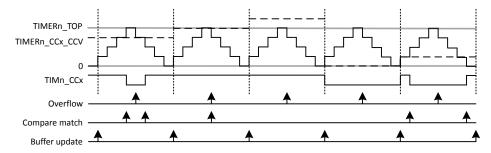

Figure 20.20. TIMER Up/Down-Count PWM Generation

$$R_{\text{PWM}_{\text{up/down}}} = \frac{\log(\text{TOP} + 1)}{\log(2)}$$

The PWM frequency is given by the following equation:

$$f_{\text{PWM}_{\text{up/down}}} = \frac{f_{\text{HFPERCLK}}}{2^{\text{PRESC+1}} \times \text{TOP}}$$

The high duty cycle is given by the following equation:

$$DS_{up} = CCVx/TOP$$

#### 20.3.2.7.1 2x Count Mode

When the Timer is set in 2x mode, the TIMER will count up/down by two. This will in effect make any odd Top value be rounded down to the closest even number. Similarly, any odd CC value will generate a match on the closest lower even value as shown in the following figure.

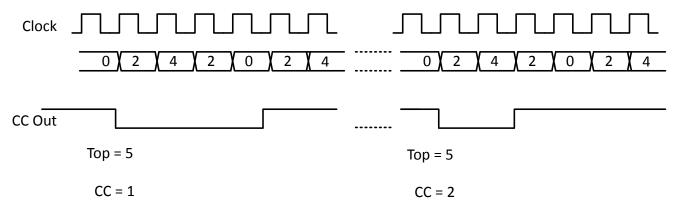

Figure 20.21. TIMER CC Out in 2x Mode

The mode is enabled by setting the X2CNT field in TIMERn\_CTRL register. The intended use of the 2x mode is to generate 2x PWM frequency when the Compare/Capture channel is put in PWM mode. Since the PWM output is updated on both edges of the clock, frequency prescaling will result in incorrect result in this mode. The PWM resolution (in bits) is then given by the following equation.

$$R_{\text{PWM}_{2\text{xmode}}} = \frac{\log(\text{TOP}/2 + 1)}{\log(2)}$$

The PWM frequency is given by the following equation:

$$f_{\text{PWM}_{2\text{xmode}}} = \frac{f_{\text{HFPERCLK}}}{\text{TOP}}$$

The high duty cycle is given by the following equation:

$$DS_{2xmode} = CCVx/TOP$$

#### 20.3.3 Dead-Time Insertion Unit (TIMER0 only)

The Dead-Time Insertion Unit aims to make control of BLDC motors safer and more efficient by introducing complementary PWM outputs with dead-time insertion and fault handling, see the following figure.

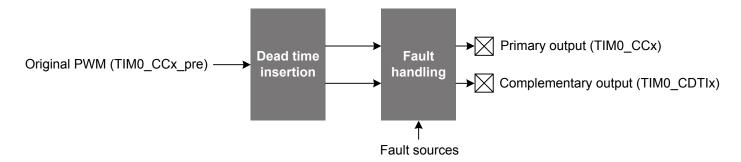

Figure 20.22. TIMER Dead-Time Insertion Unit Overview

When used for motor control, the PWM outputs TIM0\_CC0, TIM0\_CC1 and TIM0\_CC2 are often connected to the high-side transistors of a triple half-bridge setup (UH, VH and WH), and the complementary outputs connected to the respective low-side transistors (UL, VL, WL shown in the following figure). Transistors used in such a bridge often do not open/close instantaneously, and using the exact complementary inputs for the high and low side of a half-bridge may result in situations where both gates are open. This can give unnecessary current-draw and short circuit the power supply. The DTI unit provides dead-time insertion to deal with this problem.

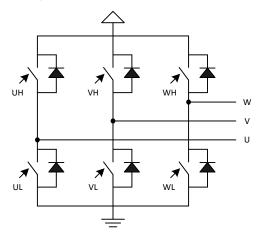

Figure 20.23. TIMER Triple Half-Bridge

For each of the 3 compare-match outputs of TIMER0, an additional complementary output is provided by the DTI unit. These outputs, named TIM0\_CDTI0, TIM0\_CDTI1 and TIM0\_CDTI2 are provided to make control of e.g. 3-channel BLDC or PMAC motors possible using only a single timer, see the following figure.

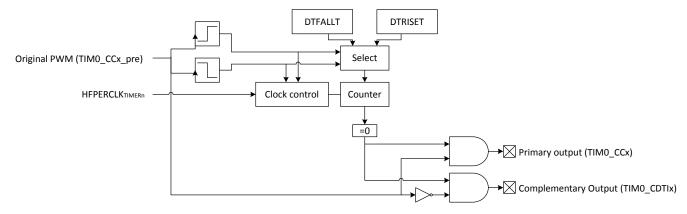

Figure 20.24. TIMER Overview of Dead-Time Insertion Block for a Single PWM Channel

The DTI unit is enabled by setting DTEN in TIMER0\_DTCTRL. In addition to providing the complementary outputs, the DTI unit then also overrides the compare match outputs from the timer.

The DTI unit gives the rising edges of the PWM outputs and the rising edges of the complementary PWM outputs a configurable time delay. By doing this, the DTI unit introduces a dead-time where both the primary and complementary outputs in a pair are inactive as seen in the following figure.

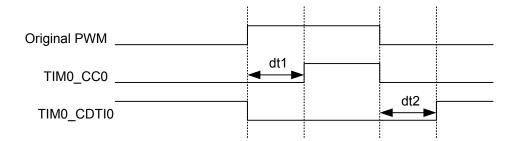

Figure 20.25. TIMER Polarity of Both Signals are Set as Active-High

Dead-time is specified individually for the rising and falling edge of the original PWM. These values are shared across all the three PWM channels of the DTI unit. A single prescaler value is provided for the DTI unit, meaning that both the rising and falling edge dead-times share prescaler value. The prescaler divides the HFPERCLK<sub>TIMERn</sub> by a configurable factor between 1 and 1024, which is set in the DTPRESC field in TIMERO\_DTTIME. The rising and falling edge dead-times are configured in DTRISET and DTFALLT in TIMERO\_DTTIME to any number between 1-64 HFPERCLK<sub>TIMERO</sub> cycles.

#### 20.3.3.1 Output Polarity

The value of the primary and complementary outputs in a pair will never be set active at the same time by the DTI unit. The polarity of the outputs can be changed however, if this is required by the application. The active values of the primary and complementary outputs are set by two the TIMERO\_DTCTRL register. The DTIPOL bit of this register specifies the base polarity. If DTIPOL =0, then the outputs are active-high, and if DTIPOL = 1 they are active-low. The relative phase of the primary and complementary outputs is not changed by DTIPOL, as the polarity of both outputs is changed, see Figure 20.26 TIMER Output Polarities on page 689.

In some applications, it may be required that the primary outputs are active-high, while the complementary outputs are active-low. This can be accomplished by manipulating the DTCINV bit of the TIMER0\_DTCTRL register, which inverts the polarity of the complementary outputs relative to the primary outputs.

TIMER DTI Example 1

DTIPOL = 0 and DTCINV = 0 results in outputs with opposite phase and active-high states.

TIMER DTI Example 2

DTIPOL = 1 and DTCINV = 1 results in outputs with equal phase. The primary output will be active-high, while the complementary will be active-low.

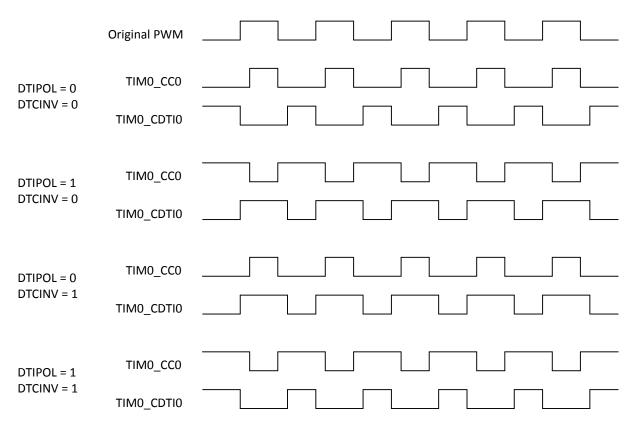

Figure 20.26. TIMER Output Polarities

Output generation on the individual DTI outputs can be disabled by configuring TIMER0\_DTOGEN. When output generation on an output is disabled, it will go to and stay in its inactive state.

#### 20.3.3.2 PRS Channel as Source

A PRS channel can optionally be used as input to the DTI module instead of the PWM output from the timer. Setting DTPRSEN in TIMER0\_DTCTRL will override the source of the first DTI channel, driving TIM0\_CC0 and TIM0\_CDTI0, with the value on the PRS channel. The rest of the DTI channels will continue to be driven by the PWM output from the timer. The PRS channel to use is chosen by configuring DTPRSSEL in TIMER0\_DTCTRL. Note that the timer must be running even when PRS is used as DTI source.

The DTI prescaler, set by DTPRESC in TIMERO\_DTTIME determines with which accuracy the DTI can insert dead-time into a PRS signal. The maximum dead-time error equals 2<sup>DTPRESC</sup> clock cycles. With zero prescaling, the inserted dead-times are therefore accurate, but they may be inaccurate for larger prescaler settings.

#### 20.3.3.3 Fault Handling

The fault handling system of the DTI unit allows the outputs of the DTI unit to be put in a well-defined state in case of a fault. This hardware fault handling system makes a fast reaction to faults possible, reducing the possibility of damage to the system.

The fault sources which trigger a fault in the DTI module are determined by TIMER0\_DTFSEN. Any combination of the available error sources can be selected:

- PRS source 0, determined by DTPRS0FSEL in TIMER0 DTFC
- PRS source 1, determined by DTPRS1FSEL in TIMER0 DTFC
- Debugger
- · Core Lockup

One or two PRS channels can be used as an error source. When PRS source 0 is selected as an error source, DTPRS0FSEL determines which PRS channel is used for this source. DTPRS1FSEL determines which PRS channel is selected as PRS source 1. Please note that for Core Lockup, the LOCKUPRDIS in RMU CTRL must be set. Otherwise this will generate a full reset of the EFM32.

#### 20.3.3.3.1 Action on Fault

When a fault occurs, the bit representing the fault source is set in DTFS, and the outputs from the DTI unit are set to a well-defined state. The following options are available, and can be enabled by configuring DTFACT in TIMER0\_DTFC:

- · Set outputs to inactive level
- · Clear outputs
- · Tristate outputs

With the first option enabled, the output state in case of a fault depends on the polarity settings for the individual outputs. An output set to be active high will be set low if a fault is detected, while an output set to be active low will be driven high.

When a fault occurs, the fault source(s) can be read out of TIMER0\_DTFS. TIMER0\_DTFS is organized in the same way as DTFSEN, with one bit for each source.

#### 20.3.3.3.2 Exiting Fault State

When a fault is triggered by the PRS system, software intervention is required to re-enable the outputs of the DTI unit. This is done by manually clearing TIMER0\_DTFS. If the fault cause, determined by TIMER0\_DTFS, is the debugger alone, the outputs can optionally be re-enabled when the debugger exits and the processor resumes normal operation. The corresponding bit in TIMER0\_DTFS will in that case be cleared by hardware. The automatic start-up functionality can be enabled by setting DTDAS in TIMER0\_DTCTRL. If more bits are still set in DTFS when the automatic start-up functionality has cleared the debugger bit, the DTI module does not exit the fault state. The fault state is only exited when all the bits in TIMER0\_DTFS have been cleared.

#### 20.3.3.4 Configuration Lock

To prevent software errors from making changes to the DTI configuration, a configuration lock is available. Writing any value but 0xCE80 to LOCKKEY in TIMER0\_DTLOCK results in TIMER0\_DTFC, TIMER0\_DTCTRL, TIMER0\_DTTIME and TIMER0\_ROUTE being locked for writing. To unlock the registers, write 0xCE80 to LOCKKEY in TIMER0\_DTLOCK. The value of TIMER0\_DTLOCK is 1 when the lock is active, and 0 when the registers are unlocked.

#### 20.3.4 Debug Mode

When the CPU is halted in debug mode, the timer can be configured to either continue to run or to be frozen. This is configured in DBGHALT in TIMERn\_CTRL.

#### 20.3.5 Interrupts, DMA and PRS Output

The Timer has 5 output events:

- · Counter Underflow
- · Counter Overflow
- · Compare match or input capture (one per Compare/Capture channel)

Each of the events has its own interrupt flag. Also, there is one interrupt flag for each Compare/Capture channel which is set on buffer overflow in capture mode. Buffer overflow happens when a new capture pushes an old unread capture out of the TIMERn\_CCx\_CCV/TIMERn\_CCx\_CCVB register pair.

If the interrupt flags are set and the corresponding interrupt enable bits in TIMERn\_IEN) are set high, the Timer will send out an interrupt request. Each of the events will also lead to a one HFPERCLK<sub>TIMERn</sub> cycle high pulse on individual PRS outputs.

Each of the events will also set a DMA request when they occur. The different DMA requests are cleared when certain acknowledge conditions are met, see the following table. If DMACLRACT is set in TIMERn\_CTRL, the DMA request is cleared when the triggered DMA channel is active, without having to access any timer registers.

Table 20.3. TIMER Events

Event	Acknowledge
Underflow/Overflow	Read or write to TIMERn_CNT or TIMERn_TOPB
CC 0	Read or write to TIMERn_CC0_CCV or TIMERn_CC0_CCVB
CC 1	Read or write to TIMERn_CC1_CCV or TIMERn_CC1_CCVB
CC 2	Read or write to TIMERn_CC2_CCV or TIMERn_CC2_CCVB

#### 20.3.6 GPIO Input/Output

The TIMn\_CCx inputs/outputs and TIM0\_CDTIx outputs are accessible as alternate functions through GPIO. Each pin connection can be enabled/disabled separately by setting the corresponding CCxPEN or CDTIxPEN bits in TIMERn\_ROUTE. The LOCATION bits in the same register can be used to move all enabled pins to alternate pins.

### 20.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	TIMERn_CTRL	RW	Control Register

26	CCPOL2	0	R	CC2 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn\_CC2\_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 2. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode		Description
0	LOWRISE		CC2 polarity low level/rising edge
1	HIGHFALL		CC2 polarity high level/falling edge
CCPOL1	0	R	CC1 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn\_CC1\_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 1. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode		Description
0	LOWRISE		CC1 polarity low level/rising edge
1	HIGHFALL		CC1 polarity high level/falling edge
CCPOL0	0	R	CC0 Polarity

In Input Capture mode, this bit indicates the polarity of the edge that triggered capture in TIMERn\_CC0\_CCV. In Compare/PWM mode, this bit indicates the polarity of the selected input to CC channel 0. These bits are cleared when CCMODE is written to 0b00 (Off).

Value	Mode	Description
0	LOWRISE	CC0 polarity low level/rising edge
1	HIGHFALL	CC0 polarity high level/falling edge

23:19	Reserved	To ensur tions.	e compatibilit	ty with future devices, always write bits to 0. More information in 2.1 Conven-
18	ICV2	0	R	CC2 Input Capture Valid

This bit indicates that TIMERn\_CC2\_CCV contains a valid capture value. These bits are only used in input capture mode and are cleared when CCMODE is written to 0b00 (Off).

Value	Description
0	TIMERn_CC2_CCV does not contain a valid capture value(FIFO empty)

Bit	Name	Reset	Access	Description
	1			TIMERn_CC2_CCV contains a valid capture value(FIFO not empty)

### 21. RTC - Real Time Counter

#### **Quick Facts**

#### What?

The Real Time Counter (RTC) ensures timekeeping in low energy modes. Combined with two low power oscillators (XTAL or RC), the RTC can run in EM2 with total current consumption less than 0.95  $\mu A,$  and in EM3 with total current consumption less than 0.65  $\mu A.$ 

### Why?

Timekeeping over long time periods is required in many applications, while using as little power as possible.

#### How?

Selectable 1 kHz and 32.768 Hz oscillators that can be used as clock source and two different compare registers that can trigger a wake-up. 24-bit resolution and selectable prescaling allow the system to stay in EM2 or EM3 for a long time and still maintain reliable timekeeping.

### 21.1 Introduction

The Real Time Counter (RTC) contains a 24-bit counter and is clocked either by a 32.768 Hz crystal oscillator, a 32.768 Hz RC oscillator, or a 1 kHz RC oscillator. In addition to energy modes EM0 and EM1, the RTC is also available in EM2. This makes it ideal for keeping track of time since the RTC is enabled in EM2 where most of the device is powered down. Using the 1 kHz ULFRCO as input clock, the RTC can be used for timekeeping all the way down to EM3.

Two compare channels are available in the RTC. These can be used to trigger interrupts and to wake the device up from a low energy mode. They can also be used with the LETIMER to generate various output waveforms.

## 21.2 Features

- · 24-bit Real Time Counter.
- Prescaler
  - $32.768 \text{ kHz/2}^{\text{N}}$ , N = 0 15.
  - Overflow @ 0.14 hours for prescaler setting = 0.
  - Overflow @ 4660 hours (194 days) for prescaler setting = 15 (1 s tick).
- · Two compare registers
  - · A compare match can potentially wake-up the device from low energy modes EM1 and EM2.
  - · Second compare register can be top value for RTC.
  - · Both compare channels can trigger LETIMER.
  - · Compare match events are available to other peripherals through the Peripheral Reflex System (PRS).

### 21.3 Functional Description

The RTC is a 24-bit counter with two compare channels. The RTC is closely coupled with the LETIMER, and can be configured to trigger it on a compare match on one or both compare channels. An overview of the RTC module is shown in the following figure.

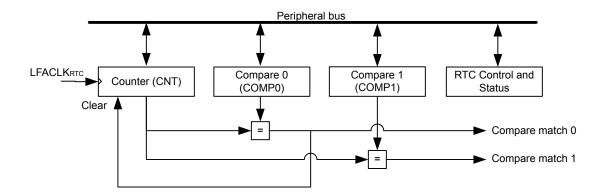

Figure 21.1. RTC Overview

## **21.3.1 Counter**

The RTC is enabled by setting the EN bit in the RTC\_CTRL register. It counts up as long as it is enabled, and will on an overflow simply wrap around and continue counting. The RTC is cleared when it is disabled. The timer value is both readable and writable and the RTC always starts counting from 0 when enabled. The value of the counter can be read or modified using the RTC\_CNT register.

#### 21.3.1.1 Clock Source

The RTC clock source and its prescaler value are defined in the Register Description section of the Clock Management Unit (CMU). The clock used by the RTC has a frequency given by the following equation.

$$f_{\text{RTC}} = \frac{f_{\text{LFACLK}}}{2^{\text{RTC\_PRESC}}}$$

where  $f_{LFACLK}$  is the LFACLK frequency (32.768 kHz) and RTC\_PRESC is a 4 bit value. The following table shows the time of overflow and resolution of the RTC at the available prescaler values.

To use this module, the LE interface clock must be enabled in CMU HFCORECLKEN0 in addition to the module clock.

Table 21.1. RTC Resolution vs Overflow

RTC_PRESC	Resolution	Overflow
0	30.5 µs	512 s
1	61.0 µs	1024 s
2	122 µs	2048 s
3	244 µs	1.14 hours
4	488 µs	2.28 hours
5	977 µs	4.55 hours
6	1.95 ms	9.10 hours
7	3.91 ms	18.2 hours
8	7.81 ms	1.52 days
9	15.6 ms	3.03 days
10	31.25 ms	6.07 days
11	62.5 ms	12.1 days
12	0.125 s	24.3 days
13	0.25 s	48.5 days
14	0.5 s	97.1 days
15	1 s	194 days

### 21.3.2 Compare Channels

Two compare channels are available in the RTC. The compare values can be set by writing to the RTC compare channel registers RTC COMPn, and when RTC CNT is equal to one of these, the respective compare interrupt flag COMPn is set.

If COMP0TOP is set, the compare value set for compare channel 0 is used as a top value for the RTC, and the timer is cleared on a compare match with compare channel 0. If using the COMP0TOP setting, make sure to set this bit prior to or at the same time the EN bit is set. Setting COMP0TOP after the EN bit is set may cause unintended operation (i.e. if CNT > COMP0).

## 21.3.2.1 LETIMER Triggers

A compare event on either of the compare channels can start the LETIMER. See the LETIMER documentation for more information on this feature.

### 21.3.2.2 PRS Sources

Both the compare channels of the RTC can be used as PRS sources. They will generate a pulse lasting one RTC clock cycle on a compare match.

### 21.3.3 Interrupts

The interrupts generated by the RTC are combined into one interrupt vector. If interrupts for the RTC is enabled, an interrupt will be made if one or more of the interrupt flags in RTC\_IF and their corresponding bits in RTC\_IEN are set. Interrupt events are overflow and compare match on either compare channels. Clearing of an interrupt flag is performed by writing to the corresponding bit in the RTC\_IFC register.

#### **21.3.4 DEBUGRUN**

By default, the RTC is halted when code execution is halted from the debugger. By setting the DEBUGRUN bit in the RTC\_CTRL register, the RTC will continue to run even when the debugger is halted.

### 21.3.5 Using the RTC in EM3

The RTC can be enabled all the way down to EM3 by using the ULFRCO as clock source. This is done by clearing CMU\_LFCLKSEL\_LFA and setting CMU\_LFCLKSEL\_LFAE to 1. This will make the RTC use the internal 1 kHz ultra low frequency RC oscillator (ULFRCO), consuming very little energy. Please note that the ULFRCO is not accurate over temperature and voltage, and it should be verified that the ULFRCO fulfills the timekeeping needs of the application before using this in the design.

### 21.3.6 Register Access

This module is a Low Energy Peripheral, and supports immediate synchronization. For description regarding immediate synchronization, refer to 5.2.4.1.1 Writing .

### 21.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

## 22. BURTC - Backup Real Time Counter

#### **Quick Facts**

#### What?

The Backup Real Time Counter (BURTC) allows timekeeping in all energy modes. Running on the LFXO, LFRCO, or ULFRCO, the BURTC can run in EM4 with a total current consumption less than 0.5uA. The Backup RTC is also available when the system is in backup mode.

### Why?

Timekeeping over long time periods is required in many applications, while using as little power as possible.

#### How?

The 32-bit Backup RTC is available in all energy modes and selectable prescaling allows the system to stay in low energy modes for long a time and still maintain reliable timekeeping. The BURTC also includes a feature allowing seamless switching of clock frequency, while maintaining resolution of the counter.

#### 22.1 Introduction

The Backup Real Time Counter (BURTC) contains a 32-bit counter and is clocked either by a 32.768 kHz crystal oscillator, a 32.768 kHz RC oscillator, a 2kHz RC oscillator, or a 1kHz RC oscillator. A variety of prescaler settings are also available for the 32.768 kHz oscillators. The Backup RTC is available in all energy modes, making it ideal for time keeping with minimal energy consumption. The ability to keep running while the system is in backup mode allows the Backup RTC to keep track of time, even if the main power should drain out.

## 22.2 Features

- · 32-bit Real Time Counter
- Prescaler for LFXO and LFRCO, 32.768 kHz/2<sup>N</sup>, N = 0-7
- · Available in all energy modes and backup mode.
- Timestamp and optionally switch to low power mode upon entry to backup mode.
- · Oscillator failure detection.
- EM4 operation and wake-up.
- · Not reset by system reset, only by software, pin reset, or power loss.
- · Seamless frequency shifting while keeping track of time.
- · 512 bytes of general purpose data retention.
- · Detection of corrupt writes to retention registers when losing main power.
- · PRS producer.

### 22.3 Functional Description

The Backup RTC is a 32-bit counter with one compare channel. The Backup RTC resides in a power domain which can be configured to always be on, in EM0 through EM4. This domain also has the possibility to be powered by a backup battery. For further details on the backup power domain, refer to 10.3.4 Backup Power Domain. Available in all energy modes, the Backup RTC is ideal for applications where keeping track of time in combination with extremely low energy consumption is essential. An overview of the backup RTC is shown in the following figure.

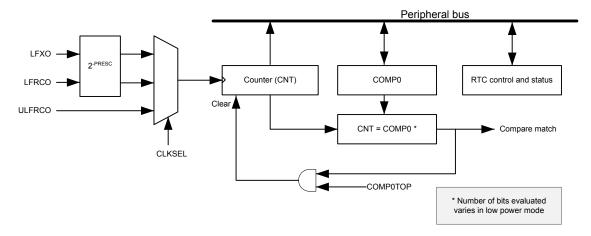

Figure 22.1. BURTC Overview

#### **22.3.1 Counter**

The Backup RTC is enabled by configuring MODE in the BURTC\_CTRL register. This configuration of MODE determines in which energy modes the backup RTC is operational. It will always be operational in EM0-EM2, and optionally in EM3 and EM4. The Backup RTC is available when the system is in backup mode if MODE is set to EM4EN. The counter is cleared by setting RSTEN in the control register. A system reset will not clear the counter. The counter value can be read through the CNT register.

## 22.3.2 Clock Source

The Backup RTC is clocked by LFXO, LFRCO, or ULFRCO, depending on the configuration of CLKSEL in BURTC\_CTRL. The PRESC bit-field in BURTC\_CTRL controls the clock prescaling factor. Prescaler is only available for LFXO and LFRCO. When using the ULFRCO as clock source, only two frequency options are available; 2kHz and 1kHz. The 2kHz clock is selected when PRESC in BURTC\_CTRL is set to DIV1, and the 1kHz clock is selected when PRESC is set to any other value. Available frequencies when using LFXO or LFRCO are given in the following equation. CLKSEL should not be changed while the backup RTC is running.

$$f_{\text{BURTC}} = \frac{32768}{2^{\text{PRESC}}}$$
Hz, PRESC = 0 to 7

When the LFXO or LFRCO is enabled, the Backup RTC will not use the clock until the timeout defined in the CMU has run out, i.e. the LFXORDY/LFRCORDY flag in CMU\_STATUS is set. When an oscillator first has been enabled and is used by the Backup RTC, the Backup RTC will keep the selected clock source enabled, independent of both energy mode and CMU settings.

## 22.3.3 Compare Channel

The backup RTC has one compare channel. The compare value is set by writing to the COMP0 register. When the value of CNT equals the value of COMP0, the COMP0 interrupt flag is set. If COMP0TOP in CTRL is set, the counter will wrap around when reaching the value in the compare register, COMP.

If COMP0TOP is cleared, the counter will continue counting, wrapping around when it overflows. On overflow, the OF interrupt flag is set.

## 22.3.4 PRS Sources

The compare channel of the Backup RTC can be used as PRS source. A pulse lasting one clock cycle will be generated on a compare match. A PRS pulse will also be generated on overflow.

### 22.3.5 Debug Run

By default, the backup RTC is halted when code execution is halted by the debugger. By setting the DEBUGRUN bit in the CTRL register, the backup RTC will continue to run even when the system is halted.

#### 22.3.6 Low Power Mode

The Backup RTC has a low power mode which lowers the power consumption at the expense of decreased resolution on compare matches. The low power mode is enabled by configuring the LPMODE bit-field in BURTC\_CTRL. When LPMODE is set to ENABLE, low power mode is always enabled, if LPMODE is set to BUEN, the Backup RTC operates in normal mode until the system enters backup mode, refer to 10.3.4 Backup Power Domain for details on backup mode. When the Backup RTC operates in low power mode, a configurable number of the LSBs of COMP0 are ignored for compare match evaluation. The number of bits ignored is configured in the LPCOMP bit-field in the BURTC\_CTRL register. The following equation is used to calculate compare match resolution in low power mode.

In low power mode, the Backup RTC will decrease its frequency by a factor of 2<sup>-LPCOMP</sup>, and start incrementing with 2<sup>LPCOMP</sup> instead of 1. When reading the counter value from software, full resolution is maintained, the decrease in frequency will only affect the resolution on compare matches. Low power mode can be entered and exited while the Backup RTC is running. When the Backup RTC is operating in low power mode, LPMODEACT in BURTC STATUS is set.

$$CM_{resolution} = \frac{2^{PRESC+LPCOMP+1}}{F_{CLK}}, PRESC + LPCOMP + 1 < 9$$

PRESC	Normal Mo	ode	Low Power I	Mode
PRESC	Compare Match Resolution	Overflow	Compare Match Resolution	Overflow
0	30.5 μs	1.52 days	Previous equation	1.52 days
1	61 µs	3.03 days	Previous equation	3.03 days
2	122 µs	6.07 days	Previous equation	6.07 days
3	244 µs	12.14 days	Previous equation	12.14 days
4	488 µs	24.27 days	Previous equation	24.27 days
5	977 µs	48.54 days	Previous equation	48.54 days
6	1.95 ms	97.09 days	Previous equation	97.09 days
7	3.91 ms	194.18 days	Previous equation	194.18 days

Table 22.1. Resolution and Overflow

Note: Low power mode is only available when using LFXO or LFRCO.

## 22.3.7 Retention Registers

The Backup RTC includes 128 x 32 bit registers with possible retention in all energy modes. The registers are accessible through the RETx\_REG registers. Retention is by default enabled in EM0 through EM4. The registers can be shut off to save power by setting RAM in BURTC POWERDOWN. Note that the retention registers cannot be accessed when RSTEN in BURTC CTRL is set.

Note: The retention registers are mapped to a RAM instance and have undefined state out of reset.

If the system should lose main power and enter backup mode while writing to the retention registers, the RAM write error flag, RAM-WERR, in BURTC\_STATUS will be set, and the attempted write will be canceled. The RAMWERR flag is cleared by writing a 1 to CLRSTATUS in BURTC\_CMD.

#### 22.3.8 Backup Operation

The Backup RTC and the retention registers reside in a separate power domain, which in addition to being available in EM4 has the possibility to be powered by a backup battery. Refer to 10.3.4 Backup Power Domain for further details on this power domain.

#### 22.3.9 Backup Mode Timestamp

The Backup RTC includes functionality for storing a timestamp when the system enters backup mode. The timestamp is stored in the BURTC\_TIMESTAMP register and is stored two cycles after entering backup mode. If Low Power mode is enabled, ignored bits will not be stored in the timestamp register. Timestamping is enabled by setting BUMODETSEN in BURTC\_CTRL. When a timestamp is stored, the BUMODETS bit in BUCTRL\_STATUS is set. To prevent uncontrolled time stamping when entering and exiting backup mode, this status bit has to be cleared before a new timestamp can be stored, by writing a 1 to CLRSTATUS in BURTC\_CMD. Note that upon clearing this bit, the data in BURTC\_TIMESTAMP is no longer valid.

#### 22.3.10 LFXO Failure Detection

To be able to detect LFXO failure, the Backup RTC includes a five bit down counter with configurable top value. The top value is configured in TOP in BURTC\_LFXOFDET. The counter starts at the top value and counts downwards on either LFRCO or ULFRCO, depending on the configuration of OSC in BURTC\_LFXOFDET. When LFRCO is selected as clock for the down counter, it will be prescaled with a factor of 2<sup>PRESC + LPCOMP</sup>. The counter wraps to TOP when it reaches zero. If no LFXO clock has arrived since the last time the counter reached zero , the BURTC clock is changed to the clock source configured in OSC and the LFXOFAIL interrupt flag is set. Note that due to synchronization, the LFXO clock needs to arrive at least two cycles before the counter reaches zero.

#### 22.3.11 Register Access

Most Backup RTC configuration should not be changed while the counter is running, i.e. they should only be changed while RSTEN in BURTC CTRL is set.

Registers allowed to change run-time are BURTC\_COMP0, BURTC\_LPMODE, and DEBUGRUN in BURTC\_CTRL. For further details on access to these registers, refer to 5.2.4 Access to Low Energy Peripherals (Asynchronous Registers).

**Note:** The Backup domain has its own reset signal which is active when the device powers up for the first time. The reset is deactivated by clearing BURSTEN in RMU\_CTRL. This has to be done before any registers in the Backup RTC can be accessed.

## 22.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description

## 23. LETIMER - Low Energy Timer

#### **Quick Facts**

#### What?

The LETIMER is a down-counter that can keep track of time and output configurable waveforms. Running on a 32.768 Hz clock the LETIMER is available in EM2, while using a 1 kHz clock the LETIMER is available also in EM3, all this with sub  $\mu$ A current consumption.

### Why?

The LETIMER can be used to provide repeatable waveforms to external components while remaining in EM2. It is well suited for e.g. metering systems or to provide more compare values than available in the RTC.

### How?

With buffered repeat and top value registers, the LE-TIMER can provide glitch-freewaveforms at frequencies up to 16 kHz. It is tightly coupled to the RTC, which allows advanced time-keeping and wake-upfunctions in EM2 and EM3.

#### 23.1 Introduction

The unique LETIMER<sup>TM</sup>, the Low Energy Timer, is a 16-bit timer that is available in energy mode EM2 and EM3, in addition to EM1 and EM0. Because of this, it can be used for timing and output generation when most of the device is powered down, allowing simple tasks to be performed while the power consumption of the system is kept at an absolute minimum.

The LETIMER can be used to output a variety of waveforms with minimal software intervention. It is also connected to the Real Time Counter (RTC), and can be configured to start counting on compare matches from the RTC.

### 23.2 Features

- · 16-bit down count timer
- · 2 Compare match registers
- · Compare register 0 can be top timer top value
- · Compare registers can be double buffered
- Double buffered 8-bit Repeat Register
- · Same clock source as the Real Time Counter
- · LETIMER can be triggered (started) by an RTC event or by software
- · 2 output pins can optionally be configured to provide different waveforms on timer underflow:
  - · Toggle output pin
  - Apply a positive pulse (pulse width of one LFACLK<sub>LETIMER</sub> period)
  - PWM
- · Interrupt on:
  - · Compare matches
  - · Timer underflow
  - · Repeat done
- Optionally runs during debug
- PRS Output

#### 23.3 Functional Description

An overview of the LETIMER module is shown in the following figure. The LETIMER is a 16-bit down-counter with two compare registers, LETIMERn\_COMP0 and LETIMERn\_COMP1. The LETIMERn\_COMP0 register can optionally act as a top value for the counter. The repeat counter LETIMERn\_REP0 allows the timer to count a specified number of times before it stops. Both the LETIMERn\_COMP0 and LETIMERn\_REP0 registers can be double buffered by the LETIMERn\_COMP1 and LETIMERn\_REP1 registers to allow continuous operation. The timer can generate a single pin output, or two linked outputs.

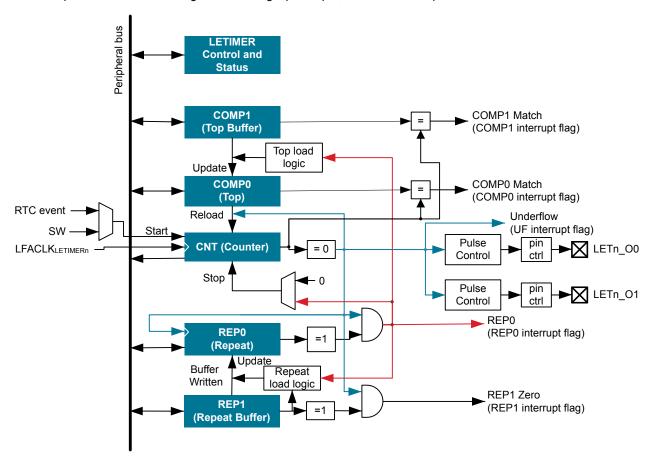

Figure 23.1. LETIMER Overview

## 23.3.1 Timer

The timer is started by setting command bit START in LETIMERn\_CMD, and stopped by setting the STOP command bit in the same register. RUNNING in LETIMERn\_STATUS is set as long as the timer is running. The timer can also be started on external signals, such as a compare match from the Real Time Counter. If START and STOP are set at the same time, STOP has priority, and the timer will be stopped.

The timer value can be read using the LETIMERn\_CNT register. The value cannot be written, but it can be cleared by setting the CLEAR command bit in LETIMERn\_CMD. If the CLEAR and START commands are issued at the same time, the timer will be cleared, then start counting at the top value.

### 23.3.2 Compare Registers

The LETIMER has two compare match registers, LETIMERn\_COMP0 and LETIMERn\_COMP1. Each of these compare registers are capable of generating an interrupt when the counter value LETIMERn\_CNT becomes equal to their value. When LETIMERn\_CNT becomes equal to the value of LETIMERn\_COMP0, the interrupt flag COMP0 in LETIMERn\_IF is set, and when LETIMERn\_CNT becomes equal to the value of LETIMERn\_COMP1, the interrupt flag COMP1 in LETIMERn\_IF is set.

### 23.3.3 Top Value

If COMP0TOP in LETIMERn\_CTRL is set, the value of LETIMERn\_COMP0 acts as the top value of the timer, and LETIMERn\_COMP0 is loaded into LETIMERn\_CNT on timer underflow. Else, the timer wraps around to 0xFFFF. The underflow interrupt flag UF in LETIMERn IF is set when the timer reaches zero.

### 23.3.3.1 Buffered Top Value

If BUFTOP in LETIMERn\_CTRL is set, the value of LETIMERn\_COMP0 is buffered by LETIMERn\_COMP1. In this mode, the value of LETIMERn\_COMP1 is loaded into LETIMERn\_COMP0 every time LETIMERn\_REP0 is about to decrement to 0. This can for instance be used in conjunction with the buffered repeat mode to generate continually changing output waveforms.

Write operations to LETIMERn\_COMP0 have priority over buffer loads.

### 23.3.3.2 Repeat Modes

By default, the timer wraps around to the top value or 0xFFFF on each underflow, and continues counting. The repeat counters can be used to get more control of the operation of the timer, including defining the number of times the counter should wrap around. Four different repeat modes are available, see the following table.

**Table 23.1. LETIMER Repeat Modes** 

REPMODE	Mode	Description
00	Free	The timer runs until it is stopped
01	One-shot	The timer runs as long as LETIMERn_REP0 != 0. LETI-MERn_REP0 is decremented at each timer underflow.
10	Buffered	The timer runs as long as LETIMERn_REP0 != 0. LETI-MERn_REP0 is decremented on each timer underflow. If LETI-MERn_REP1 has been written, it is loaded into LETIMERn_REP0 when LETIMERn_REP0 is about to be decremented to 0.
11	Double	The timer runs as long as LETIMERn_REP0 != 0 or LETI-MERn_REP1 != 0. Both LETIMERn_REP0 and LETIMERn_REP1 are decremented at each timer underflow.

The interrupt flags REP0 and REP1 in LETIMERn\_IF are set whenever LETIMERn\_REP0 or LETIMERn\_REP1 are decremented to 0 respectively. REP0 is also set when the value of LETIMERn\_REP1 is loaded into LETIMERn\_REP0 in buffered mode.

### 23.3.3.2.1 Free Mode

In the free running mode, the LETIMER acts as a regular timer, and the repeat counter is disabled. When started, the timer runs until it is stopped using the STOP command bit in LETIMERn\_CMD. A state machine for this mode is shown in the following figure.

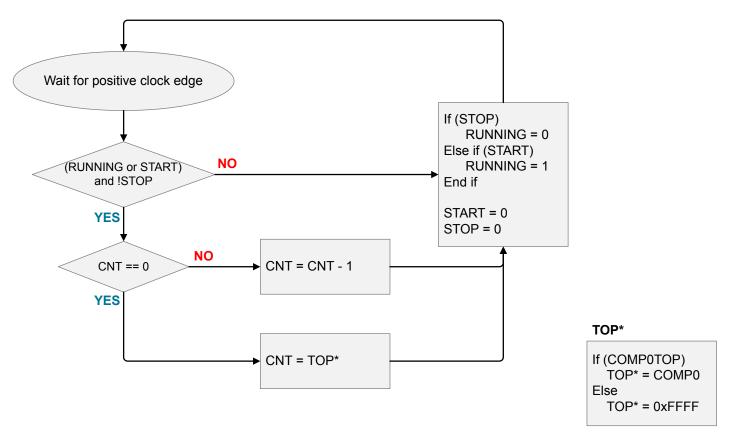

Figure 23.2. LETIMER State Machine for Free-Running Mode

Note that the CLEAR command bit in LETIMERn\_CMD always has priority over other changes to LETIMERn\_CNT. When the clear command is used, LETIMERn\_CNT is set to 0 and an underflow event will not be generated when LETIMERn\_CNT wraps around to the top value or 0xFFFF. Since no underflow event is generated, no output action is performed. LETIMERn\_REP0, LETIMERn\_REP1, LETIMERn\_COMP0 and LETIMERn\_COMP1 are also left untouched.

#### 23.3.3.2.2 One-shot Mode

The one-shot repeat mode is the most basic repeat mode. In this mode, the repeat register LETIMERn\_REP0 is decremented every time the timer underflows, and the timer stops when LETIMERn\_REP0 goes from 1 to 0. In this mode, the timer counts down LETIMERn\_REP0 times, i.e. the timer underflows LETIMERn\_REP0 times.

**Note:** Note that write operations to LETIMERn\_REP0 have priority over the decrementation operation. So if LETIMERn\_REP0 is assigned a new value in the same cycle it was supposed to be decremented, it is assigned the new value instead of being decremented.

LETIMERn\_REP0 can be written while the timer is running to allow the timer to run for longer periods at a time without stopping. See the following figure.

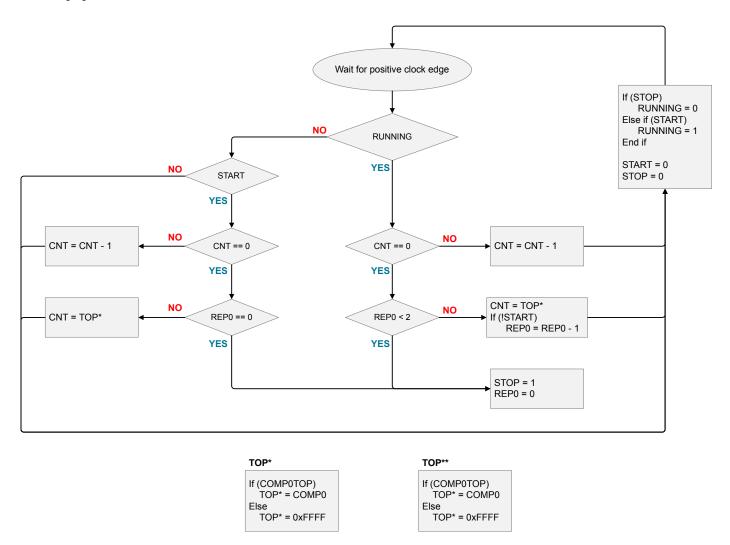

Figure 23.3. LETIMER One-Shot Repeat State Machine

#### 23.3.3.2.3 Buffered Mode

The Buffered repeat mode allows buffered timer operation. When started, the timer runs LETIMERn\_REP0 number of times. If LETI-MERn\_REP1 has been written since the last time it was used and it is nonzero, LETIMERn\_REP1 is then loaded into LETI-MERn\_REP0, and counting continues the new number of times. The timer keeps going as long as LETIMERn\_REP1 is updated with a nonzero value before LETIMERn\_REP0 is finished counting down.

If the timer is started when both LETIMERn\_CNT and LETIMERn\_REP0 are zero but LETIMERn\_REP1 is non-zero, LETIMERn\_REP1 is loaded into LETIMERn\_REP0, and the counter counts the loaded number of times. The state machine for the one-shot repeat mode is shown in the following figure.

Used in conjunction with a buffered top value, enabled by setting BUFTOP in LETIMERn\_CTRL, the buffered mode allows buffered values of both the top and repeat values of the timer, and the timer can for instance be set to run 4 times with period 7 (top value 6), 6 times with period 200, then 3 times with period 50.

A state machine for the buffered repeat mode is shown in the following figure. REP1<sub>USED</sub> shown in the state machine is an internal variable that keeps track of whether the value in LETIMERn\_REP1 has been loaded into LETIMERn\_REP0 or not. The purpose of this is that a value written to LETIMERn\_REP1 should only be counted once. REP1<sub>USED</sub> is cleared whenever LETIMERn\_REP1 is written.

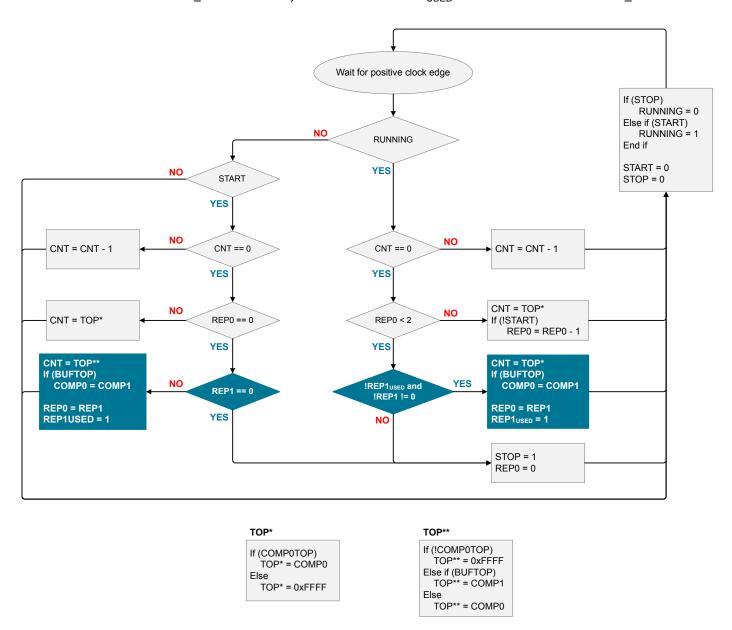

Figure 23.4. LETIMER Buffered Repeat State Machine

#### 23.3.3.2.4 Double Mode

The Double repeat mode works much like the one-shot repeat mode. The difference is that, where the one-shot mode counts as long as LETIMERn\_REP0 is larger than 0, the double mode counts as long as either LETIMERn\_REP0 or LETIMERn\_REP1 is larger than 0. As an example, say LETIMERn\_REP0 is 3 and LETIMERn\_REP1 is 10 when the timer is started. If no further interaction is done with the timer, LETIMERn\_REP0 will now be decremented 3 times, and LETIMERn\_REP1 will be decremented 10 times. The timer counts a total of 10 times, and LETIMERn\_REP0 is 0 after the first three timer underflows and stays at 0. LETIMERn\_REP0 and LETIMERn\_REP1 can be written at any time. After a write to either of these, the timer is guaranteed to underflow at least the written number of times if the timer is running. Use the Double repeat mode to generate output on both the LETIMER outputs at the same time. The state machine for this repeat mode can be seen in the following figure.

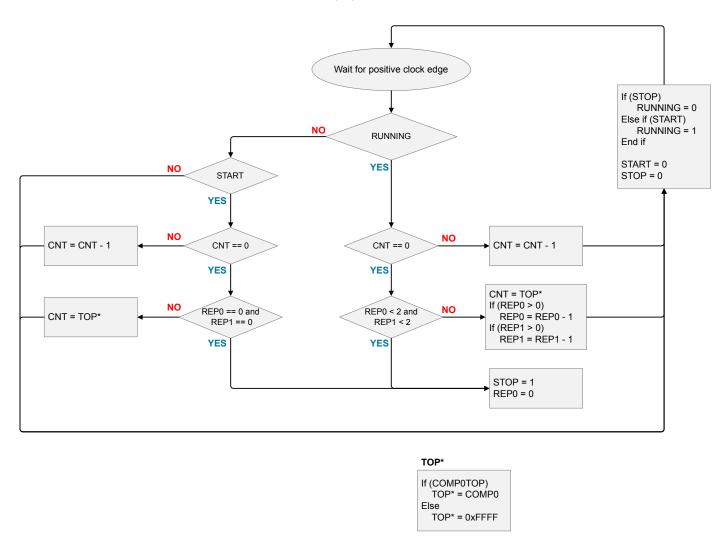

Figure 23.5. LETIMER Double Repeat State Machine

### 23.3.3.3 Clock Source

Clock Source The LETIMER clock source and its prescaler value are defined in the Clock Management Unit (CMU). The LFACLK<sub>LETI-</sub> has a frequency given by the following equation.

$$f_{\text{LFACLK\_LETIMERn}} = \frac{32.768}{2^{\text{LETIMERn}}}$$

where the exponent LETIMERn is a 4 bit value in the CMU\_LFAPRESC0 register.

To use this module, the LE interface clock must be enabled in CMU HFCORECLKENO, in addition to the module clock.

#### 23.3.3.4 RTC Trigger

The LETIMER can be configured to start on compare match events from the Real Time Counter (RTC). If RTCC0TEN in LETI-MERn\_CTRL is set, the LETIMER will start on a compare match on RTC compare channel 0. In the same way, RTCC1TEN in LETI-MERn\_CTRL enables the LETIMER to start on a compare match with RTC compare channel 1.

**Note:** The LETIMER can only use compare match events from the RTC if the LETIMER runs at a higher than or equal frequency than the RTC. Also, if the LETIMER runs at twice the frequency of the RTC, a compare match event in the RTC will trigger the LETIMER twice. Four times the frequency gives four consecutive triggers, etc. The LETIMER will only continue running if triggered while it is running, so the multiple-triggering will only have an effect if you try to disable the RTC when it is being triggered.

#### 23.3.3.5 Debug

If DEBUGRUN in LETIMERn\_CTRL is cleared, the LETIMER automatically stops counting when the CPU is halted during a debug session, and resumes operation when the CPU continues. Because of synchronization, the LETIMER is halted two clock cycles after the CPU is halted, and continues running two clock cycles after the CPU continues. RUNNING in LETIMERn\_STATUS is not cleared when the LETIMER stops because of a debug-session.

Set DEBUGRUN in LETIMERn\_CTRL to allow the LETIMER to continue counting even when the CPU is halted in debug mode.

### 23.3.4 Underflow Output Action

For each of the repeat registers, an underflow output action can be set. The configured output action is performed every time the counter underflows while the respective repeat register is nonzero. In PWM mode, the output is similarly only changed on COMP1 match if the repeat register is nonzero. As an example, the timer will perform 7 output actions if LETIMERn\_REP0 is set to 7 when starting the timer in one-shot mode and leaving it untouched for a while.

The output actions can be set by configuring UFOA0 and UFOA1 in LETIMERn\_CTRL. UFOA0 defines the action on output 0, and is connected to LETIMERn\_REP0, while UFOA1 defines the action on output 1 and is connected to LETIMERn\_REP1. The possible actions are defined in the following table.

UF0A0/UF0A1 Mode **Description** 00 Idle The output is held at its idle value 01 Toggle The output is toggled on LETIMERn\_CNT underflow if LEI-MERn REPx is nonzero 10 Pulse The output is held active for one clock cycle on LETIMERn CNT underflow if LETIMERn\_REPx is nonzero. It then returns to its idle value 11 **PWM** The output is set idle on LETIMERn CNT underflow and active on compare match with LETIMERn\_COMP1 if LETIMERn\_REPx is nonzero.

**Table 23.2. LETIMER Underflow Output Actions** 

**Note:** For the Pulse and PWM modes, the outputs will return to their idle states regardless of the state of the corresponding LETI-MERn REPx registers. They will only be set active if the LETIMERn REPx registers are nonzero however.

The polarity of the outputs can be set individually by configuring OPOL0 and OPOL1 in LETIMERn\_CTRL. When these are cleared, their respective outputs have a low idle value and a high active value. When they are set, the idle value is high, and the active value is low.

When using the toggle action, the outputs can be driven to their idle values by setting their respective CTO0/CTO1 command bits in LETIMERn\_CTRL. This can be used to put the output in a well-defined state before beginning to generate toggle output, which may be important in some applications. The command bit can also be used while the timer is running.

Some simple waveforms generated with the different output modes are shown in the following figure. For the example, REPMODE in LETIMERn\_CTRL has been cleared, COMP0TOP also in LETIMERn\_CTRL has been set and LETIMERn\_COMP0 has been written to 3. As seen in the figure, LETIMERn\_COMP0 now decides the length of the signal periods. For the toggle mode, the period of the output signal is 2(LETIMERn\_COMP0 + 1), and for the pulse modes, the periods of the output signals are LETIMERn\_COMP0+1. Note that the pulse outputs are delayed by one period relative to the toggle output. The pulses come at the end of their periods.

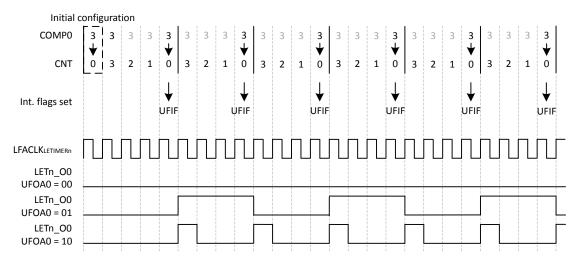

Figure 23.6. LETIMER Simple Waveforms Output

For the example in the following figure, the One-shot repeat mode has been selected, and LETIMERn\_REP0 has been written to 3. The resulting behavior is pretty similar to that shown in Figure 6, but in this case, the timer stops after counting to zero LETI-MERn\_REP0 times. By using LETIMERn\_REP0 the user has full control of the number of pulses/toggles generated on the output.

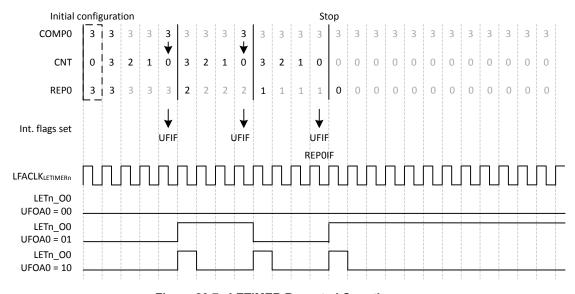

Figure 23.7. LETIMER Repeated Counting

Using the Double repeat mode, output can be generated on both the LETIMER outputs. The following figure shows an example of this. UFOA0 and UFOA1 in LETIMERn\_CTRL are configured for pulse output and the outputs are configured for low idle polarity. As seen in the figure, the number written to the repeat registers determine the number of pulses generated on each of the outputs.

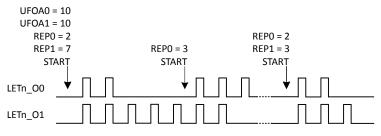

Figure 23.8. LETIMER Dual Output

## 23.3.5 PRS Output

The LETIMER outputs can be routed out onto the PRS system. LETn\_00 can be routed to PRS channel 0, and LETn\_10 can be routed to PRS channel 1. Enabling the RRS connection can be done by setting SOURCESEL to LETIMERx and SIGSEL to LETIMERxCHn in PRS\_CHx\_CTRL. The PRS register description can be found in 13. PRS - Peripheral Reflex System.

### 23.3.6 Examples

This section presents a couple of usage examples for the LETIMER.

### 23.3.6.1 Triggered Output Generation

If both LETIMERn\_CNT and LETIMERn\_REP0 are 0 in buffered mode, and COMP0TOP and BUFTOP in LETIMERn\_CTRL are set, the values of LETIMERn\_COMP1 and LETIMERn\_REP1 are loaded into LETIMERn\_CNT and LETIMERn\_REP0 respectively when the timer is started. If no additional writes to LETIMERn\_REP1 are done before the timer stops, LETIMERn\_REP1 determines the number of pulses/ toggles generated on the output, and LETIMERn\_COMP1 determines the period lengths.

As the RTC can be used to start the LETIMER, the RTC and LETIMER can thus be combined to generate specific pulse-trains at given intervals. Software can update LETIMERn\_COMP1 and LETIMERn\_REP1 to change the number of pulses and pulse-period in each train, but if changes are not required, software does not have to update the registers between each pulse train.

For the example in the following figure, the initial values cause the LETIMER to generate two pulses with 3 cycle periods, or a single pulse 3 cycles wide every time the LETIMER is started. After the output has been generated, the LETIMER stops, and is ready to be triggered again.

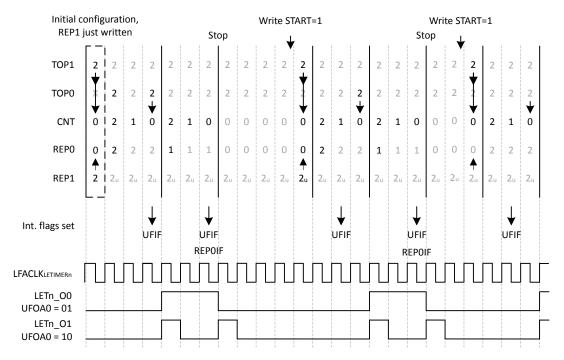

Figure 23.9. LETIMER Triggered Operation

#### 23.3.6.2 Continuous Output Generation

In some scenarios, it might be desired to make LETIMER generate a continuous waveform. Very simple constant waveforms can be generated without the repeat counter as shown in Figure 23.6 LETIMER Simple Waveforms Output on page 755, but to generate changing waveforms, using the repeat counter and buffer registers can prove advantageous.

For the example in the following figure, the goal is to produce a pulse train consisting of 3 sequences with the following properties:

- · 3 pulses with periods of 3 cycles
- · 4 pulses with periods of 2 cycles
- · 2 pulses with periods of 3 cycles

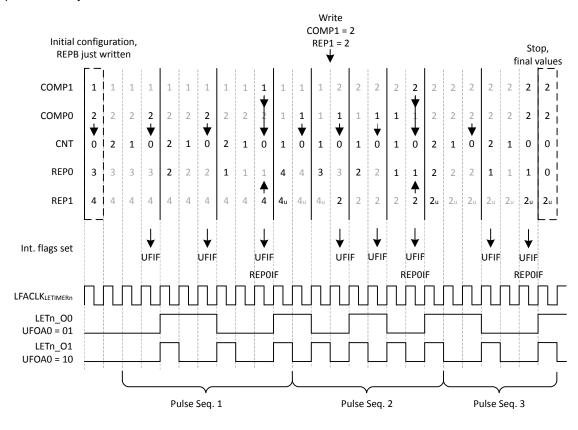

Figure 23.10. LETIMER Continuous Operation

The first two sequences are loaded into the LETIMER before the timer is started.

LETIMERn\_COMP0 is set to 2 (cycles – 1), and LETIMERn\_REP0 is set to 3 for the first sequence, and the second sequence is loaded into the buffer registers, i.e. COMP1 is set to 1 and LETIMERn\_REP1 is set to 4.

The LETIMER is set to trigger an interrupt when LETIMERn\_REP0 is done by setting REP0 in LETIMERn\_IEN. This interrupt is a good place to update the values of the buffers. Last but not least REPMODE in LETIMERn\_CTRL is set to buffered mode, and the timer is started.

In the interrupt routine the buffers are updated with the values for the third sequence. If this had not been done, the timer would have stopped after the second sequence.

The final result is shown in the previous figure. The pulse output is grouped to show which sequence generated which output. Toggle output is also shown in the figure. Note that the toggle output is not aligned with the pulse outputs.

**Note:** Multiple LETIMER cycles are required to write a value to the LETIMER registers. The example in the previous figure assumes that writes are done in advance so they arrive in the LETIMER as described in the figure.

The following figure shows an example where the LETIMER is started while LETIMERn\_CNT is nonzero. In this case the length of the first repetition is given by the value in LETIMERn\_CNT.

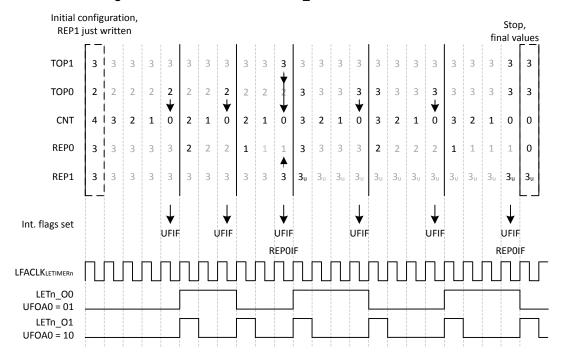

Figure 23.11. LETIMER LETIMERn\_CNT Not Initialized to 0

#### 23.3.6.3 PWM Output

There are several ways of generating PWM output with the LETIMER, but the most straight-forward way is using the PWM output mode. This mode is enabled by setting UFOA0 or OFUA1 in LETIMERn\_CTRL to 3. In PWM mode, the output is set idle on timer underflow, and active on LETIMERn\_COMP1 match, so if for instance COMP0TOP = 1 and OPOL0 = 0 in LETIMERn\_CTRL, LETIMERn\_COMP0 determines the PWM period, and LETIMERn\_LETIMERn\_COMP1 determines the active period.

The PWM period in PWM mode is LETIMERn\_COMP0 + 1. There is no special handling of the case where LETIMERn\_COMP1 > LETIMERn\_COMP0, so if LETIMERn\_COMP1 > LETIMERn\_COMP0, the PWM output is given by the idle output value. This means that for OPOLx = 0 in LETIMERn\_CTRL, the PWM output will always be 0 for at least one clock cycle, and for OPOLx = 1 LETIMERn\_CTRL, the PWM output will always be 1 for at least one clock cycle.

To generate a PWM signal using the full PWM range, invert OPOLx when LETIMERn\_COMP1 is set to a value larger than LETI-MERn COMP0.

#### 23.3.6.4 Interrupts

The interrupts generated by the LETIMER are combined into one interrupt vector. If the interrupt for the LETIMER is enabled, an interrupt will be made if one or more of the interrupt flags in LETIMERn. IF and their corresponding bits in LETIMER IEN are set.

#### 23.3.7 Using the LETIMER in EM3

The LETIMER can be enabled all the way down to EM3 by using the ULFRCO as clock source. This is done by clearing CMU\_LFCLKSEL\_LFA and setting CMU\_LFCLKSEL\_LFAE to 1. This will make the RTC use the internal 1 kHz ultra low frequency RC oscillator (ULFRCO), consuming very little energy. Please note that the ULFRCO is not accurate over temperature and voltage, and it should be verified that the ULFRCO fulfills the timekeeping needs of the application before using this in the design.

#### 23.3.8 Register Access

This module is a Low Energy Peripheral, and supports immediate synchronization. For description regarding immediate synchronization, refer to 5.2.4.1.1 Writing.

# 23.4 Register Map

#### 24. PCNT - Pulse Counter

#### **Quick Facts**

#### What?

The Pulse Counter (PCNT) decodes incoming pulses. The module has a quadrature mode which may be used to decode the speed and direction of a mechanical shaft. PCNT can operate in EM0- EM3.

#### Why?

The PCNT generates an interrupt after a specific number of pulses (or rotations), eliminating the need for timing- or I/O interrupts and CPU processing to measure pulse widths, etc.

#### How?

PCNT uses the LFACLK or may be externally clocked from a pin. The module incorporates an 8/16-bit up/down-counter to keep track of incoming pulses or rotations.

#### 24.1 Introduction

The Pulse Counter (PCNT) can be used for counting incoming pulses on a single input or to decode quadrature encoded inputs. It can run from the internal LFACLK (EM0-EM2) while counting pulses on the PCNTn\_S0IN pin or using this pin as an external clock source (EM0-EM3) that runs both the PCNT counter and register access.

#### 24.2 Features

- · 16/8-bit counter with reload register
- · Auxiliary counter for counting a single direction
- Single input oversampling up/down counter mode (EM0-EM2)
- Externally clocked single input pulse up/down counter mode (EM0-EM3)
- Externally clocked quadrature decoder mode (EM0-EM3)
- · Interrupt on counter underflow and overflow
- Interrupt when a direction change is detected (quadrature decoder mode only)
- · Optional pulse width filter
- · Optional input inversion/edge detect select
- · PRS S0IN and S1IN input

#### 24.3 Functional Description

An overview of the PCNT module is shown in the following figure.

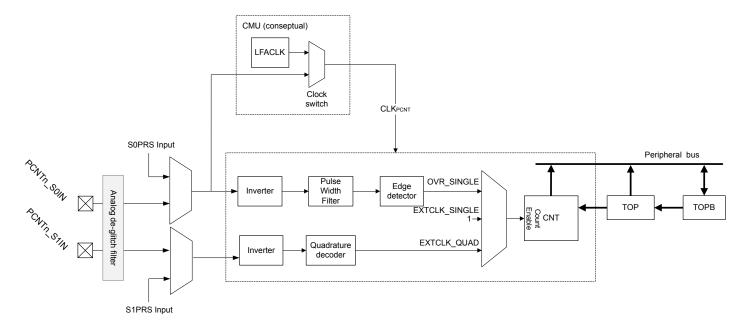

Figure 24.1. PCNT Overview

#### 24.3.1 Pulse Counter Modes

The pulse counter can operate in single input oversampling mode (OVSSINGLE), externally clocked single input counter mode (EXTCLKSINGLE) and externally clocked quadrature decoder mode (EXTCLKQUAD). The following sections describe operation of each of the three modes and how they are enabled. Input timing constraints are described in 24.3.5 Clock Sources and 24.3.6 Input Filter.

#### 24.3.1.1 Single Input Oversampling Mode

This mode is enabled by writing OVSSINGLE to the MODE field in the PCNTn\_CTRL register and disabled by writing DISABLE to the same field. LFACLK is configured from the registers in 11. CMU - Clock Management Unit.

The optional pulse width filter is enabled by setting the FILT bit in the PCNTn\_CTRL register. Additionally, the PCNTn\_S0IN input may be inverted, so that falling edges are counted, by setting the EDGE bit in the PCNTn\_CTRL register.

If S1CDIR is cleared, PCNTn\_S0IN is the only observed input in this mode. The PCNTn\_S0IN input is sampled by the LFACLK and the number of detected positive or negative edges on PCNTn\_S0IN appears in PCNTn\_CNT. The counter may be configured to count down by setting the CNTDIR bit in PCNTn\_CTRL. Default is to count up.

The counting direction can also be controlled externally in this mode by setting S1CDIR in PCNTn\_CTRL. This will make the input value on PCNTn\_S1IN decide the direction counted on a PCNTn\_S0IN edge. If PCNTn\_S1IN is high, the count is done according to CNTDIR in PCNTn\_CTRL. If low, the count direction is opposite.

#### 24.3.1.2 Externally Clocked Single Input Counter Mode

This mode is enabled by writing EXTCLKSINGLE to the MODE field in the PCNTn\_CTRL register and disabled by writing DISABLE to the same field. The external pin clock source must be configured from the registers in 11. CMU - Clock Management Unit.

Positive edges on PCNTn\_S0IN are used to clock the counter. Similar to the oversampled mode, PCNTn\_S1IN is used to determine the count direction if S1CDIR in PCNTn\_CTRL is set. If not, CNTDIR in PCNTn\_CTRL solely defines count direction. As the LFACLK is not used in this mode, the PCNT module can operate in EM3.

The digital pulse width filter is not available in this mode. The analog de-glitch filter in the GPIO pads is capable of removing some unwanted noise. However, this mode may be susceptible to spikes and unintended pulses from devices such as mechanical switches, and is therefore most suited to take input from electronic sensors etc. that generate single wire pulses.

### 24.3.1.3 Externally Clocked Quadrature Decoder Mode

This mode is enabled by writing EXTCLKQUAD to the MODE field in PCNTn\_CTRL and disabled by writing DISABLE to the same field. The external pin clock source must be configured from the registers in 11. CMU - Clock Management Unit.

Both edges on PCNTn\_S0IN pin are used to sample PCNTn\_S1IN pin to decode the quadrature code. Consequently, this mode does not depend on the internal LFACLK and may be operated in EM3. A quadrature coded signal contains information about the relative speed and direction of a rotating shaft as illustrated by the following figure, hence the direction of the counter register PCNTn\_CNT is controlled automatically.

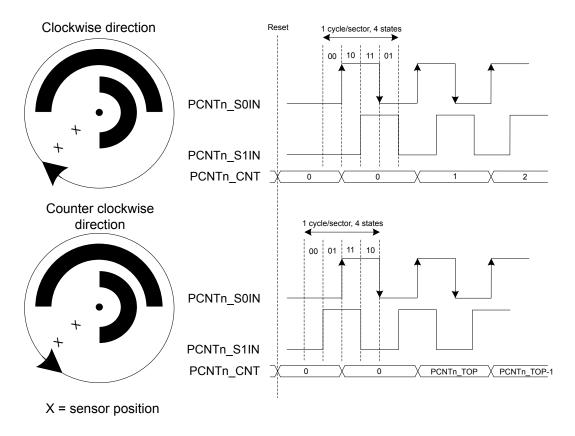

Figure 24.2. PCNT Quadrature Coding

If PCNTn\_S0IN leads PCNTn\_S1IN in phase, the direction is clockwise, and if it lags in phase the direction is counter-clockwise. Although the direction is automatically detected, the detected direction may be inverted by writing 1 to the EDGE bit in the PCNTn\_CTRL register. Default behavior is illustrated by the previous figure.

The counter direction may be read from the DIR bit in the PCNTn\_STATUS register. Additionally, the DIRCNG interrupt in the PCNTn\_IF register is generated when a direction change is detected. When a change is detected, the DIR bit in the PCNTn\_STATUS register must be read to determine the current new direction.

**Note:** The sector disc illustrated in the figure may be finer grained in some systems. Typically, they may generate 2-4 PCNTn\_S0IN wave periods per 360° rotation.

The direction of the quadrature code and control of the counter is generated by the simple binary function outlined by the following table. Note that this function also filters some invalid inputs that may occur when the shaft changes direction or temporarily toggles direction.

Table 24.1. PCNT QUAD Mode Counter Control Function

Control/Status

Inputs		Control/Status	
S1IN posedge	S1IN negedge	Count Enable	CNTDIR status bit
0	0	0	0
0	1	1	0

Inputs		Control/Status	
S1IN posedge	S1IN negedge	Count Enable	CNTDIR status bit
1	0	1	1
1	1	0	0

Note: PCNTn\_S1IN is sampled on both edges of PCNTn\_S0IN.

#### 24.3.2 Hysteresis

By default the pulse counter wraps to 0 when passing the configured top value, and wraps to the top value when counting down from 0. On these events, a system will likely want to wake up to store and track the overflow count. This is fine if the pulse counter is tracking a monotonic value or a value that does not change directions frequently. If you have the latter however, and the counter changes directions around the overflow/underflow point, the system will have to wake up a lot to keep track of the rotations, causing high current consumptions

To solve this, the pulse counter has a way of introducing hysteresis to the counter. When HYST in PCNTn\_CTRL is set, the pulse counter will always wrap to TOP/2 on underflows and overflows. This takes the counter away from the area where it might overflow or underflow, removing the problem.

Given a starting value of 0 for the counter, the absolute count value when hysteresis is enabled can be calculated with the following equations, depending on whether the TOP value is even or odd.

Absolute position with hysteresis and even TOP value

$$CNT_{abs} = CNT - UF_{CNT} \times (\frac{TOP}{2} + 1) + OF_{CNT} \times (\frac{TOP}{2} + 1)$$

Absolute position with hysteresis and odd TOP value

$$CNT_{abs} = CNT - UF_{CNT} \times (\frac{TOP}{2} + 1) + OF_{CNT} \times (\frac{TOP}{2} + 2)$$

### 24.3.3 Auxiliary Counter

To be able to keep explicit track of counting in one direction in addition to the regular counter which counts both up and down, the auxiliary counter can be used. The pulse counter can for instance be configured to keep track of the absolute rotation of the wheel, and at the same time the auxiliary counter can keep track of how much the wheel has reversed.

The auxiliary counter is enabled by configuring AUXCNTEV in PCNTn\_CTRL. It will always count up, but it can be configured whether it should count up on up-events, down-events or both, keeping track of rotation either way or general movement. The value of the auxiliary counter can be read from the PCNTn\_AUXCNT register.

Overflows on the auxiliary counter happen when the auxiliary counter passes the top value of the pulse counter, configured in PCNTn TOP. In that event, the AUXOF interrupt flag is set, and the auxiliary counter wraps to 0.

As the auxiliary counter, the main counter can be configured to count only on certain events. This is done through CNTEV in PCNTn\_CTRL, and it is possible like for the auxiliary counter, to make the main counter count on only up and down events. The difference between the counters is that where the auxiliary counter will only count up, the main counter will count up or down depending on the direction of the count event.

#### 24.3.4 Register Access

The counter-clock domain may be clocked externally. To update the counter-clock domain registers from software in this mode, 2-3 clock pulses on the external clock are needed to synchronize accesses to the externally clocked domain. Clock source switching is controlled from the registers in 11. CMU - Clock Management Unit.

When the RSTEN bit in the PCNTn\_CTRL register is set to 1, the PCNT clock domain is asynchronously held in reset. The reset is synchronously released two PCNT clock edges after the RSTEN bit in the PCNTn\_CTRL register is cleared by software. This asynchronous reset restores the reset values in PCNTn\_TOP, PCNTn\_CNT and other control registers in the PCNT clock domain.

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to 5.2.4 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals.

**Note:** PCNTn\_TOP and PCNTn\_CNT are read-only registers. When writing to PCNTn\_TOPB, make sure that the counter value, PCNTn CNT, can not exceed the value written to PCNTn TOPB within two clock cycles.

#### 24.3.5 Clock Sources

The 32 kHz LFACLK is one of two possible clock sources. The clock select register is described in 11. CMU - Clock Management Unit. The default clock source is the LFACLK.

This PCNT module may also use PCNTn\_S0IN as an external clock to clock the counter (EXTCLKSINGLE mode) and to sample PCNTn\_S1IN (EXTCLKQUAD mode). Setup, hold and max frequency constraints for PCNTn\_S0IN and PCNTn\_S1IN for these modes are specified in the device datasheet.

To use this module, the LE interface clock must be enabled in CMU HFCORECLKEN0, in addition to the module clock.

**Note:** PCNT Clock Domain Reset, RSTEN, should be set when changing clock source for PCNT. If changing to an external clock source, the clock pin has to be enabled as input prior to deasserting RSTEN. Changing clock source without asserting RSTEN results in undefined behaviour.

### 24.3.6 Input Filter

An optional pulse width filter is available in OVSSINGLE mode. The filter is enabled by writing 1 to the FILT bit in the PCNTn\_CTRL register. When enabled, the high and low periods of PCNTn\_S0IN must be stable for 5 consecutive clock cycles before the edge is passed to the edge detector.

In EXTCLKSINGLE and EXTCLKQUAD mode, there is no digital pulse width filter available.

#### 24.3.7 Edge Polarity

The edge polarity can be set by configuring the EDGE bit in the PCNTn\_CTRL register. When this bit is cleared, the pulse counter counts positive edges in OVSSINGLE mode and negative edges if the bit is set.

In EXTCLKQUAD mode, the EDGE bit in PCNTn CTRL inverts the direction of the counter (which is automatically detected).

Note: The EDGE bit in PCNTn CTRL has no effect in EXTCLKSINGLE mode.

#### 24.3.8 PRS S0IN and S1IN Input

It is possible to receive input from PRS on both SOIN and S1IN by setting S0PRSEN or S1PRSEN in PCNTn\_INPUT. The PRS channel used can be selected using S0PRSSEL in PCNTn\_INPUT.

### 24.3.9 Interrupts

The interrupt generated by PCNT uses the PCNTn\_INT interrupt vector. Software must read the PCNTn\_IF register to determine which module interrupt that generated the vector invocation.

#### 24.3.9.1 Underflow and Overflow Interrupts

The underflow interrupt flag (UF) is set when the counter counts down from 0. I.e. when the value of the counter is 0 and a new pulse is received. The PCNTn\_CNT register is loaded with the PCNTn\_TOP value after this event.

The overflow interrupt flag (OF) is set when the counter counts up from the PCNTn\_TOP (reload) value. I.e. if PCNTn\_CNT = PCNTn TOP and a new pulse is received. The PCNTn CNT register is loaded with the value 0 after this event.

#### 24.3.9.2 Direction Change Interrupt

The PCNTn\_PCNT module sets the DIRCNG interrupt flag (PCNTn\_IF register) when the direction of the quadrature code changes. The behavior of this interrupt is illustrated by the following figure.

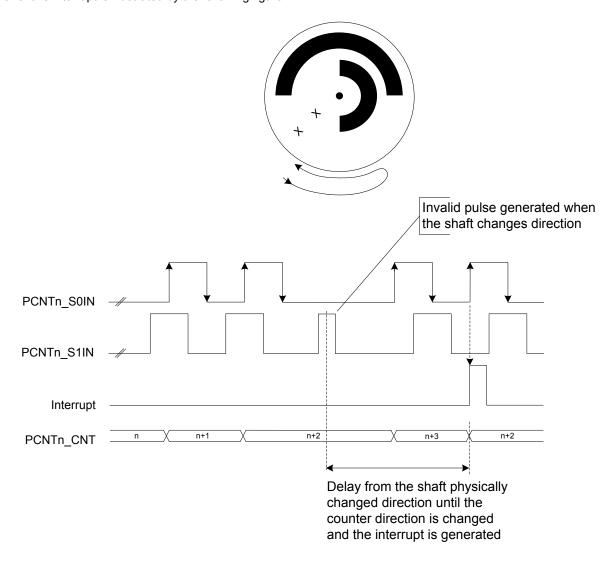

Figure 24.3. PCNT Direction Change Interrupt (DIRCNG) Generation

### 25. LESENSE - Low Energy Sensor Interface

#### **Quick Facts**

#### What?

LESENSE is a low energy sensor interface capable of autonomously collecting and processing data from multiple sensors even when in EM2. Flexible configuration makes LESENSE a versatile sensor interface compatible with a wide range of sensors and measurement schemes.

### Why?

Capability to autonomously monitor sensors allows the EFM32WG to reside in a low energy mode for long periods of time while keeping track of sensor status and sensor events.

#### How?

LESENSE is highly configurable and is capable of collecting data from a wide range of sensor types. Once the data is collected, the programmable state machine, LESENSE decoder, is capable of processing sensor data without CPU intervention. A large result buffer allows the chip to remain in EM2 for long periods of time while autonomously collecting data.

#### 25.1 Introduction

LESENSE is a low energy sensor interface which utilizes on-chip peripherals to perform measurement of a configurable set of sensors. The results from sensor measurements can be processed by the LESENSE decoder, which is a configurable state machine with up to 16 states. The results can also be stored in a result buffer to be collected by CPU or DMA for further processing.

LESENSE operates in EM2, in addition to EM1 and EM0, and can wake up the CPU on configurable events.

#### 25.2 Features

- · Up to 16 sensors
- Autonomous sensor monitoring in EM0, EM1, and EM2
- · Highly configurable decoding of sensor results
- · Interrupt on sensor events
- · Configurable enable signals to external sensors
- · Circular buffer for storage of up to 16 sensor results.
- · Support for multiple sensor types
  - LC sensors
  - · Capacitive sensing
  - · General analog sensors

## 25.3 Functional Description

LESENSE is a module capable of controlling on-chip peripherals in order to perform monitoring of different sensors with little or no CPU intervention. LESENSE uses the analog comparators, ACMP, for measurement of sensor signals. LESENSE can also control the DAC to generate accurate reference voltages. The following figure shows an overview of the LESENSE module. LESENSE consists of a sequencer, count and compare block, a decoder, and a RAM block used for configuration and result storage. The sequencer handles interaction with other peripherals as well as timing of sensor measurements. The count and compare block is used to count pulses from ACMP outputs before comparing with a configurable threshold. To autonomously analyze sensor results, the LESENSE decoder provides possibility to define a finite state machine with up to 16 states, and programmable actions upon state transitions. This allows the decoder to implement a wide range of decoding schemes, for instance quadrature decoding. A RAM block is used for storage of configuration and measurement results. This allows LESENSE to have a relatively large result buffer enabling the chip to remain in a low energy mode for long periods of time while collecting sensor data.

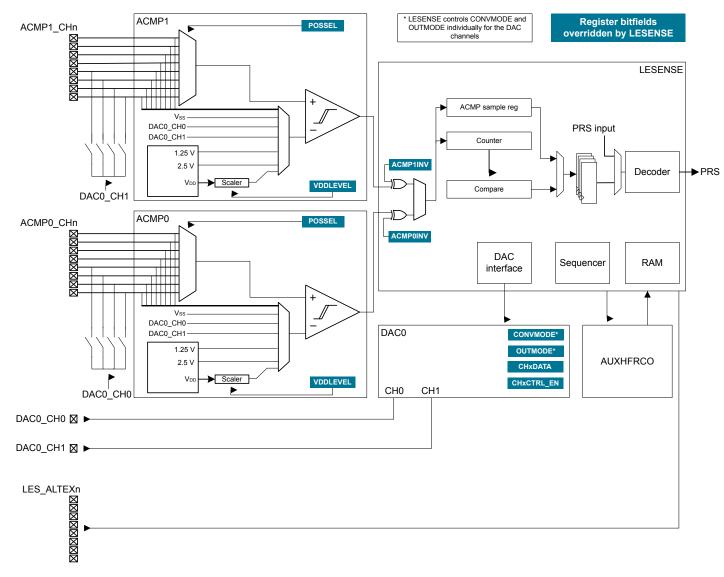

Figure 25.1. LESENSE Block Diagram

### 25.3.1 Channel Configuration

LESENSE has 16 individually configurable channels, the first eight are mapped to the channels of ACMP0, while the last eight are mapped to the channels of ACMP1. Each LESENSE channel has its own set of configuration registers. Channel configuration is split into three registers; CHx\_TIMING, CHx\_INTERACT, and CHx\_EVAL. Individual timing for each sensor is configured in CHx\_TIMING, sensor interaction is configured in CHx\_INTERACT, and configurations regarding evaluation of the measurements are done in CHx\_EVAL. For improved readability, CHx\_CONF will be used to address the channel configuration registers, CHx\_TIMING, CHx\_INTERACT, and CHx\_EVAL, throughout this chapter.

By default, the channel configuration registers are directly mapped to the channel number. Configuring SCANCONF in CTRL makes it possible to alter this mapping.

Configuring SCANCONF to INVMAP will make channels 0-7 use the channel configuration registers for channels 8-15, and vice versa. This feature allows an application to quickly and easily switch configuration set for the channels.

Setting SCANCONF to TOGGLE will make channel x alternate between using  $CH_{X_-}CONF$  and  $CH_{X_-+8}$ \_CONF. The configuration used is decided by the state of the corresponding bit in SCANRES. For instance, if channel 3 is performing a scan and bit 3 in SCANRES is set,  $CH_{11}$ \_CONF will be used. Channels 8 through 15 will toggle between  $CH_{X_-}CONF$  and  $CH_{X_-8}$ \_CONF. This mode provides an easy way for implementation of hysteresis on channel events as threshold values can be changed depending on sensor status.

Setting SCANCONF to DECDEF will make the state of the decoder define which scan configuration to be used. If the decoder state is at index 8 or higher, channel x will use  $CH_{X+8}$ \_CONF, otherwise it will use CHX configuration. Similarly, channels 8 through 15 will use  $CH_X$  configuration when decoder state index is less than 8 and  $CH_{X-8}$ \_CONF when decoder state index is higher than 7. Allowing the decoder state to define which configuration to use, enables easy implementation of for instance hysteresis, as different threshold values can be used for the same channel, depending on the state of the application. The table below summarizes how channel configuration is selected for different setting of SCANCONF.

**SCANCONF** LESENSE chan-**TOGGLE DIRMAP INVMAP DECDEF** nel x SCANRES[n] = 0 SCANRES[n] = 1 DECSTATE >= 8 **DECSTATE < 8** CH<sub>x+8</sub> CONF  $0 \le x \le 8$ CH<sub>x</sub> CONF CH, CONF CH<sub>x+8</sub> CONF CH<sub>x</sub> CONF CH<sub>x+8</sub> CONF CH<sub>x</sub> CONF CH<sub>x-8</sub> CONF  $8 \le x \le 16$ CH<sub>x</sub> CONF CH<sub>x-8</sub> CONF CH<sub>x</sub> CONF CHx-8 CONF

Table 25.1. LESENSE Scan Configuration Selection

Channels are enabled in the CHEN register, where bit x enables channel x. During a scan, all enabled channels are measured, starting with the lowest indexed channel. The following figure illustrates a scan sequence with channels 3, 5, and 9 enabled.

## 25.3.2 Scan Sequence

LESENSE runs on LFACLKLESENSE, which is a prescaled version of LFACLK. The prescaling factor for LFACLK<sub>LESENSE</sub> is selected in the CMU, available prescaling factors are:

• DIV1: LFACLK<sub>LESENSE</sub> = LFACLK/1

DIV2: LFACLK<sub>I ESENSE</sub> = LFACLK/2

• DIV4: LFACLK<sub>LESENSE</sub> = LFACLK/4

DIV8: LFACLK<sub>LESENSE</sub> = LFACLK/8

Note: LFACLK<sub>LESENSE</sub> should not exceed 50kHz.

All enabled channels are scanned each scan period. How a new scan is started is configured in the SCANMODE bit field in CTRL. If set to PERIODIC, the scan frequency is generated using a counter which is clocked by LFACLK<sub>LESENSE</sub>. This counter has its own prescaler. This prescaling factor is configured in PCPRESC in TIMCTRL. A new scan sequence is started each time the counter reaches the top value, PCTOP. The scan frequency is calculated using the following equation. If SCANMODE is set to ONESHOT, a single scan will be made when START in CMD is set. To start a new scan on a PRS event, set START in CMD, set SCANMODE to PRS and configure PRS channel in PRSSEL. The PRS start signal needs to be active for at least one LFACLKLESENSE cycle to make sure LESENSE is able to register it.

$$F_{\text{scan}} = \frac{\text{LFACLK}_{\text{LESENSE}}}{(1 + \text{PCTOP}) \times 2^{\text{PCPRESC}}}$$

It is possible to interleave additional sensor measurements in between the periodic scans. Issuing a start command when LESENSE is idle will immediately start a new scan, without disrupting the frequency of the periodic scans. If the period counter overflows during the interleaved scan, the periodically scheduled scan will start immediately after the interleaved scan completes.

Figure 25.2. Scan Sequence

### 25.3.3 Sensor Timing

For each channel in the scan sequence, the LESENSE interface goes through three phases: Idle phase, excite phase, and measure phase. The durations of the excite and measure phases are configured in the CHx\_TIMING registers. LESENSE includes two timers: A low frequency timer, running on LFACLK<sub>LESENSE</sub>, and a high frequency timer, running on AUXHFRCO. Timing of the excite phase is done using these timers and can be either a number of prescaled AUXHFRCO cycles or a number of prescaled LFACLK<sub>LESENSE</sub> cycles, depending on which one is selected in EXCLK. The prescaling can be done by configuring LFPRESC in TIMCTRL for the low frequency timer, and the high frequency timer prescaling factor is configured in AUXPRESC in the same register. The duration of the measure phase is programmed via MEASUREDLY and SAMPLEDLY. The output of the ACMP will be inactive for MEASUREDLY EXCLK cycles after start of the sensor measurement. Sampling of the sensor will happen after SAMPLEDLY LFACLK<sub>LESENSE</sub>, or AUXHFRCO cycles, depending on the configuration of SAMPLECLK. The following figure depicts a sensor sequence where excitation and measure delay is timed using AUXHFRCO and the sample delay is timed using LFACLK<sub>LESENSE</sub>. The configurable measure- and sample delays enables LESENSE to easily define exact time windows for sensor measurements. A start delay can be inserted before sensor measurement begin by configuring STARTDLY in TIMCTRL. This delay can be used to ensure that the DAC is done and voltages have stabilized before sensor measurement begins.

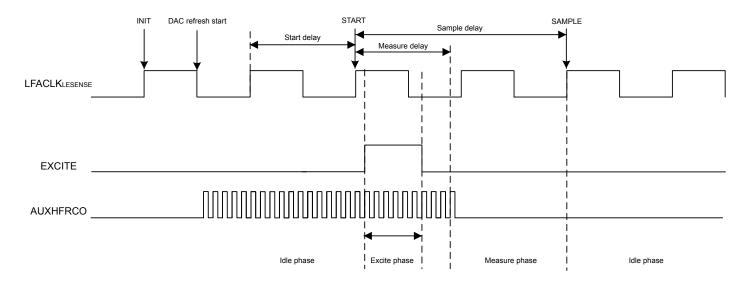

Figure 25.3. Timing Diagram, Short Excitation

#### 25.3.4 Sensor Interaction

Many sensor types require some type of excitation in order to work. LESENSE can generate a variety of sensor stimuli, both on the same pin as the measurement is to be made on, and on alternative pins.

By default, excitation is performed on the pin associated with the channel, i.e. excitation and sensor measurement is performed on the same pin. The mode of the pin during the excitation phase is configured in EXMODE in CHx\_INTERACT. The available modes during the excite phase are:

- · DISABLED: The pin is disabled.
- · HIGH: The pin is driven high.
- · LOW: The pin is driven low.
- · DACOUT: The pin is connected to the output of a DAC channel.

**Note:** Excitation with DAC output is only available on channels 0, 1, 2, and 3 (DAC0\_CH0) and channels 12, 13, 14, and 15 (DAC0\_CH1).

If the DAC is in opamp-mode, setting EXMODE to DACOUT will result in excitation with output from the opamp.

LESENSE is able to perform sensor excitation on another pin than the one to be measured. When ALTEX in CHx\_INTERACT is set, the excitation will occur on the alternative excite pin associated with the given channel. All LESENSE channels mapped to ACMP0 have their alternative channel mapped to the corresponding channel on ACMP1, and vice versa. Alternatively, the alternative excite pins can be routed to the LES\_ALTEX pins. Mapping of the alternative excite pins is configured in ALTEXMAP in CTRL. The following table summarizes the mapping of excitation pins for different configurations.

Table 25.2. LESENSE Excitation Pin Mapping

LESENSE channel	ALTEX = 0	ALTEX = 1	
		ALTEXMAP = ACMP	ALTEXMAP = ALTEX
0	ACMP0_CH0	ACMP1_CH0	LES_ALTEX0
1	ACMP0_CH1	ACMP1_CH1	LES_ALTEX1
2	ACMP0_CH2	ACMP1_CH2	LES_ALTEX2
3	ACMP0_CH3	ACMP1_CH3	LES_ALTEX3
4	ACMP0_CH4	ACMP1_CH4	LES_ALTEX4
5	ACMP0_CH5	ACMP1_CH5	LES_ALTEX5
6	ACMP0_CH6	ACMP1_CH6	LES_ALTEX6
7	ACMP0_CH7	ACMP1_CH7	LES_ALTEX7
8	ACMP1_CH0	ACMP0_CH0	LES_ALTEX0
9	ACMP1_CH1	ACMP0_CH1	LES_ALTEX1
10	ACMP1_CH2	ACMP0_CH2	LES_ALTEX2
11	ACMP1_CH3	ACMP0_CH3	LES_ALTEX3
12	ACMP1_CH4	ACMP0_CH4	LES_ALTEX4
13	ACMP1_CH5	ACMP0_CH5	LES_ALTEX5
14	ACMP1_CH6	ACMP0_CH6	LES_ALTEX6
15	ACMP1_CH7	ACMP0_CH7	LES_ALTEX7

The following figure illustrates the sequencing of the pin associated with the active channel and its alternative excite pin.

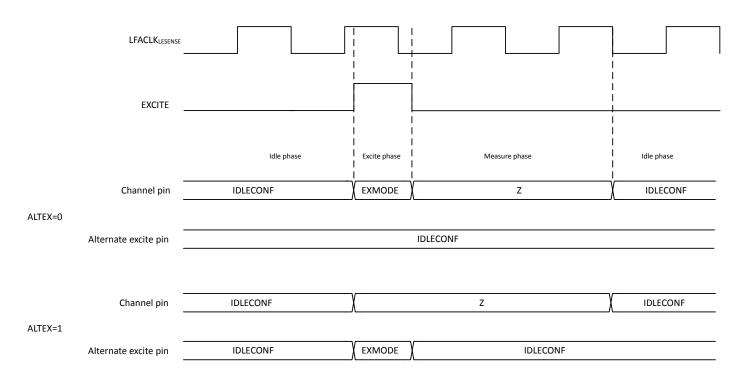

Figure 25.4. Pin Sequencing

The alternative excite pins, LES\_ALTEXn, have the possibility to excite regardless of what channel is active. Setting AEXn in ALTEX-CONF will make LES\_ALTEXn excite for all channels using alternative excitation, i.e. ALTEX in CHx\_INTERACT is set.

**Note:** When exciting on the pin associated with the active channel, the pin will go through a tristated phase before returning to the idle configuration. This will not happen on pins used as alternative excitation pins.

The pin configuration for the idle phase can be configured individually for each LESENSE channel and alternative excite pin in the IDLECONF and ALTEXCONF registers. The modes available are the same as the modes available in the excitation phase. In the measure phase, the pin mode on the active channel is always disabled (analog input).

To enable LESENSE to control GPIO, the pin has to be enabled in the ROUTE register. In addition, the given pin must be configured as push-pull. IDLECONF configuration should not be altered when pin enable for the given pin is set in ROUTE.

### 25.3.5 Sensor Evaluation

Sensor evaluation can be based on either analog comparator outputs, or the counter output. This is configured in the SAMPLE bit-field in CHx\_INTERACT. The LESENSE counter is used to count pulses on the ACMP output in the measurement phase. When a measurement phase is completed, the counter value is compared to the value configured in COMPTHRES in CHx\_EVAL. By configuring COMP, it is possible to choose comparison mode: Less than, or greater than or equal. If a comparison for a channel triggers, the corresponding bit in the result register, SCANRES, is set. To set an interrupt flag on a sensor event, configure SETIF in CHx\_INTERACT. The following figure illustrates how the counter value or ACMP sample is used for evaluation and interrupt generation.

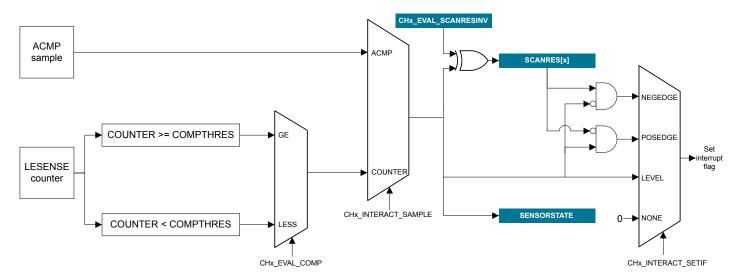

Figure 25.5. Scan Result and Interrupt Generation

LESENSE includes the possibility to sample both analog comparators simultaneously, effectively cutting the time spent on sensor interaction in some applications in half. Setting DUALSAMPLE in CTRL enables this mode. In dual sample mode, the channels of ACMPO are paired together with the corresponding channel on ACMP1, i.e. channel x on ACMPO and channel x on ACMP1 are sampled simultaneously. The results from sensor measurements can be fed into the decoder register and/or stored in the result buffer. In this mode, the samples from the AMCPs are placed in the two LSBs of the result stored in the result buffer. Results from both ACMPs will be evaluated for interrupt generation.

#### 25.3.6 Decoder

Many applications require some sort of processing of the sensor readings, for instance in the case of quadrature decoding. In quadrature decoding, the sensors repeatedly pass through a set of states which corresponds to the position of the sensors. This sequence, and many other decoding schemes, can be described as a finite state machine. To support this type of decoding without CPU intervention, LESENSE includes a highly configurable decoder, capable of decoding input from up to four sensors. The decoder is implemented as a programmable state machine with up to 16 states. When doing a sensor scan, the results from the sensors are placed in the decoder input register, SENSORSTATE, if DECODE in CHx\_INTERACT is set. The resulting position after a scan is illustrated in the following figure, where the bottom blocks show how the SENSORSTATE register is filled. When the scan sequence is complete, the decoder evaluates the state of the sensors chosen for decoding, as depicted in the following figure.

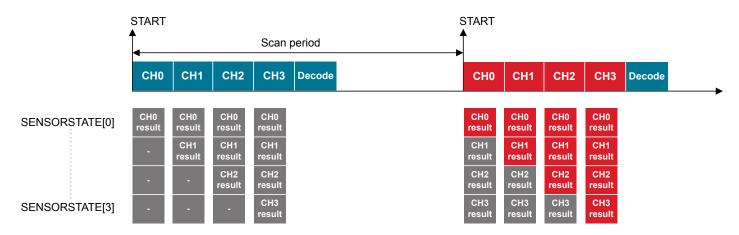

Figure 25.6. Sensor Scan and Decode Sequence

The decoder is a programmable state machine with support for up to 16 states. The behavior of each state is individually configured in the STx\_TCONFA and STx\_TCONFB registers. The registers define possible transitions from the present state. If the sensor state matches COMP in either STx\_TCONFA or STx\_TCONFB, a transition to the state defined in NEXTSTATE will be made. It is also possible to mask out one or more sensors using the MASK bit field. The state of a masked sensor is interpreted as don't care.

Upon a state transition, LESENSE can generate a pulse on one or more of the decoder PRS channels. Which channel to generate a pulse on is configured in the PRSACT bit field. If PRSCNT in DECCTRL is set, count signals will be generated on decoder PRS channels 0 and 1 according to the PRSACT configuration. In this mode, channel 0 will pulse each time a count event occurs while channel 1 indicates the count direction, 1 being up and 0 being down. The count direction will be kept at its previous state in between count events. The EFM32WG pulse counter may be used to keep track of events based on these PRS outputs.

If SETIF is set, the DECODER interrupt flag will be set when the transition occurs. If INTMAP in DECCTRL and SETIF is set, a transition from state x will set the CHx interrupt flag in addition to the DECODER flag.

Setting CHAIN in STx\_TCONFA enables the decoder to evaluate more than two possible transitions for each state. If none of the transitions defined in STx\_TCONFA or STx\_TCONFB matches, the decoder will jump to the next descriptor pair and evaluate the transitions defined there. The decoder uses two LFACLKLESENSE cycles for each descriptor pair to be evaluated. If ERRCHK in CTRL is set, the decoder will check that the sensor state has not changed if none of the defined transitions match. The DECERR interrupt flag will be set if none of the transitions match and the sensor state has changed. The following figure illustrates state transitions. The "Generate PRS signals and set interrupt flag" blocks will perform actions according to the configuration in STx\_TCONFA and STx\_TCONFB.

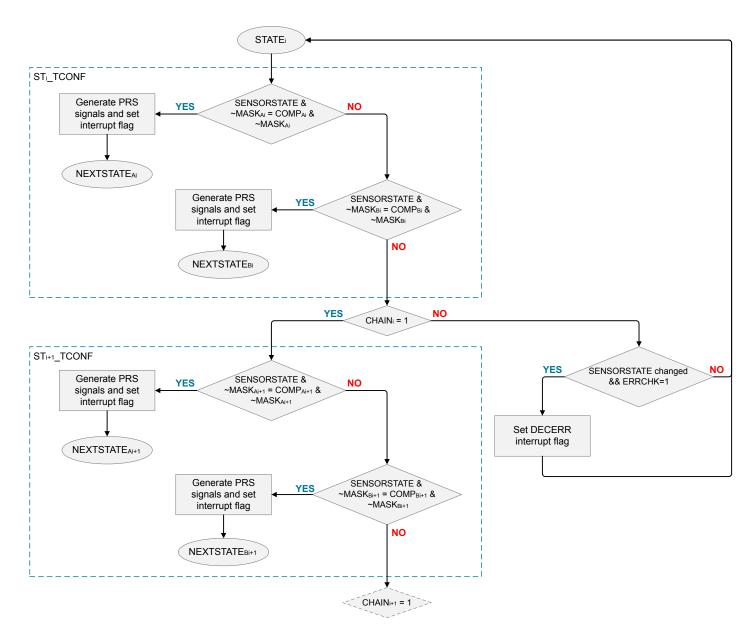

Figure 25.7. Decoder State Transition Evaluation

Note: If only one transition from a state is used, STx\_TCONFA and STx\_TCONFB should be configured equally.

To prevent unnecessary interrupt requests or PRS outputs when the decoder toggles back and forth between two states, a hysteresis option is available. The hysteresis function is triggered if a type A transition is preceded by a type B transition, and vice versa. A type A transition is a transition defined in STx\_TCONFA, and a type B transition is a transition defined in STx\_TCONFB. When descriptor chaining is used, a jump to another descriptor will cancel out the hysteresis effect. The following figure illustrates how the hysteresis triggers upon state transitions.

A transition—Transition defined in TCONFA B transition—Transition defined in TCONFB

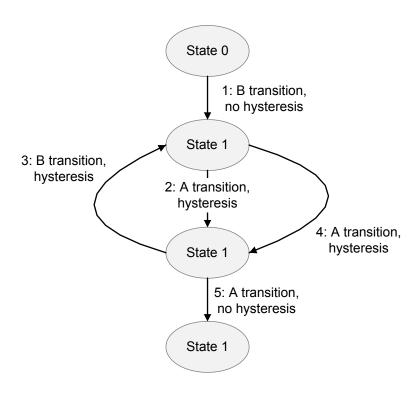

Figure 25.8. Decoder Hysteresis

The events suppressed by the hysteresis are configured in bit fields HYSTPRS0-2 and HYSTIRQ in DECCTRL.

- When HYSTPRSx is set, PRS signal x is suppressed when the hysteresis triggers.
- When HYSTIRQ is set, interrupt requests are suppressed when the hysteresis triggers.

Note: The decoder error interrupt flag, DECERR, is not affected by the hysteresis.

### 25.3.7 Measurement Results

Part of the LESENSE RAM is treated as a circular buffer for storage of up to 16 results from sensor measurements. Each time LESENSE writes data to the result buffer, the result write pointer, PTR\_WR, is incremented. Each time a new result is read through the BUFDATA register, the result read pointer, PTR\_RD, is incremented. The read pointer will not be incremented if there is no valid, unread data in the result buffer. By default LESENSE will not write additional data to a full result buffer until the data is read by software or DMA. Setting BUFOW in CTRL enables LESENSE to write to the result buffer, even if it is full. In this mode, the result read pointer will follow the write pointer if the buffer is full. The result of this is that data read from the result read register, BUFDATA, is the oldest unread result. The location pointers are available in PTR. The result buffer has three status flags; BUFDATAV, BUFHALFFULL, and BUFFULL. The flags indicate when new data is available, when the buffer is half full, and when it is full, respectively. The interrupt flag BUFDATAV is set when data is available in the buffer. BUFLEVEL is set when the buffer is either full or half-full, depending on the configuration of BUFIDL in CTRL. If the result buffer overflows, the BUFOF interrupt flag will be set.

During a scan, the state of each sensor is stored in SCANRES. If a sensor triggers, a 1 is stored in SCANRES, else a 0 is stored in SCANRES. Whether or not a sensor is said to be triggered depends of the configuration for the given channel. If SAMPLE is set to ACMP, the sensor is said to be triggered if the output from the analog comparator is 1 when sensor sampling is performed. If SAMPLE is set to COUNTER, a sensor is said to be triggered if the LESENSE counter value is greater than or equal, or less than COMPTHRES, depending on the configuration of COMP. If STRSAMPLE in CHx\_EVAL is set, the counter value or ACMP sample for each channel will be stored in the LESENSE result buffer. If STRSCANRES in CTRL is set, the result vector, SCANRES, will also be stored in the result buffer. This will be stored after each scan and will be interleaved with the counter values. The contents of the result buffer can be read from BUFDATA or from BUF[x]\_DATA. When reading from BUF[x]\_DATA, neither the result read pointer or the status flags BUFDATAV, BUFHALFFULL, or BUFFULL will be updated. When reading through the BUFDATA register, the oldest unread result will be read.

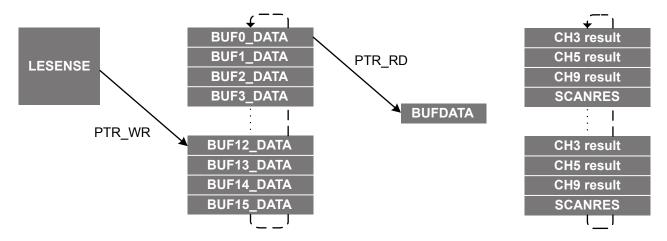

Figure 25.9. Circular Result Buffer

The right hand side of the previous figure illustrates how the result buffer would be filled when channels 3,5, and 9 are enabled and have STRSAMPLE in CHx\_EVAL set, in addition to STRSCANRES in CTRL. The measurement result from the three channels will be sequentially written during the scan, while SCANRES is written to the result buffer upon scan completion.

### 25.3.8 DAC Interface

LESENSE is able to drive the DAC for generation of accurate reference voltages. DAC channels 0 and 1 are individually configured in the PERCTRL register. The conversion mode can be set to either continuous, sample/hold or sample/off. For further details about these modes, refer to 28.3.2 Conversions. Both DAC channels are refreshed prior to each sensor measurement, as depicted in Figure 25.3 Timing Diagram, Short Excitation on page 796. The conversion data is either taken from the data registers in the EFM32WG DAC interface (DAC0\_CH0DATA and DAC0\_CH1DATA) or from the ACMPTHRES bitfield in the CHx\_INTERACT register for the active LESENSE channel. DAC data used is configured in DACCHxDATA in PERCTRL.

The DAC interface runs on AUXHFRCO and will enable this when it is needed. The DACPRESC bit-field in PERCTRL is used to prescale the AUXHFRCO to achieve wanted clock frequency for the LESENSE DAC interface. The frequency should not exceed 500kHz, i.e. DACPRESC has to be set to at least 1. The prescaler may also be used to tune how long the DAC should drive its outputs in sample/off mode.

Bias configuration, calibration and reference selection is done in the EFM32WG DAC module and LESENSE will not override these configurations. If a bandgap reference is selected for the DAC, the DACREF bit in PERCTRL should be set to BANDGAP.

LESENSE has the possibility to control switches that connect the DAC outputs to the pins associated with ACMP0\_CH0-3 and ACMP1\_CH12-15. This makes LESENSE able to excite sensors with output from the DAC channels.

The DAC may be chosen as reference to the analog comparators for accurate reference generation. If the DAC is configured in continuous or sample/hold mode this does not require any external components. If sample/off mode is used, an external capacitor is needed to keep the voltage in between samples. To connect the input from the DAC to the ACMP to this external capacitor, connect the capacitor to the DAC pin for the given channel and set OPAxSHORT in DAC\_OPACTRL.

Note: The DAC mode should not be altered while DACACTIVE in STATUS is set

#### 25.3.9 ACMP Interface

The ACMPs are used to measure the sensors, and have to be configured according to the application in order for LESENSE to work properly. Depending on the configuration in the ACMP0MODE and ACMP1MODE bit-fields in PERCTRL, LESENSE will take control of the positive input mux and the Vdd scaling factor (VDDLEVEL) for ACMP0 and ACMP1. The remaining configuration of the analog comparators are done in the ACMP register interface. It is recommended to set the MUXEN bit in ACMPn\_CTRL for the ACMPs used by LESENSE. Each channel has the possibility to control the value of the Vdd scaling factor on the negative input of the ACMP, VDDLEVEL in ACMP\_INPUTSEL. This is done in the 6 LSBs of ACMPTHRES in CHx\_INTERACT. LESENSE automatically controls the ACMP mux to connect the correct channel.

## 25.3.10 ACMP and DAC Duty Cycling

By default, the analog comparators and DAC are shut down in between LESENSE scans to save energy. If this is not wanted, WAR-MUPMODE in PERCTRL can be configured to prevent them from being shut down.

Both the DAC and analog comparators rely on a bias module for correct operation. This bias module has a low power mode which consumes less energy at the cost of reduced accuracy. BIASMODE in BIASCTRL configures how the bias module is controlled by LESENSE. When set to DUTYCYCLE, LESENSE will set the bias module in high accuracy mode whenever LESENSE is active, and keep it in the low power mode otherwise. When BIASMODE is set to HIGHACC, the high accuracy mode is always selected. When set to DONTTOUCH, LESENSE will not control the bias module.

### 25.3.11 DMA Requests

LESENSE issues a DMA request when the result buffer is either full or half full, depending on the configuration of BUFIDL in CTRL. The request is cleared when the buffer level drops below the threshold defined in BUFIDL. A single DMA request is also set whenever there is unread data in the buffer. DMAWU in CTRL configures at which buffer level LESENSE should wake-up the DMA when in EM2.

Note: The DMA controller should always fetch data from the BUFDATA register.

## 25.3.12 PRS Output

LESENSE is an asynchronous PRS producer and has nineteen PRS outputs. The decoder has three outputs and in addition, all bits in the SCANRES register are available as PRS outputs. For further information on the decoder PRS output, refer to 25.3.6 Decoder.

#### 25.3.13 RAM

LESENSE includes a RAM block used for storage of configuration and results. If LESENSE is not used, this RAM block can be powered down eliminating its current consumption due to leakage. The RAM is powered down by setting the RAM bit in the POWERDOWN register. Once the RAM has been shut down it cannot be turned back on without a reset of the chip. Registers mapped to the RAM include: STx\_TCONFA, STx\_TCONFB, BUFx\_DATA, BUFDATA, CHx\_TIMING, CHx\_INTERACT, and CHx\_EVAL. These registers have unknown value out of reset and have to be initialized before use.

Note: Read-modify-write operations on uninitialized RAM register produces undefined values.

### 25.3.14 Application Examples

## 25.3.14.1 Capacitive Sense

The following figure illustrates how the EFM32WG can be configured to monitor four capacitive buttons.

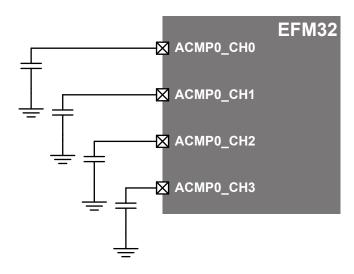

Figure 25.10. Capacitive Sense Setup

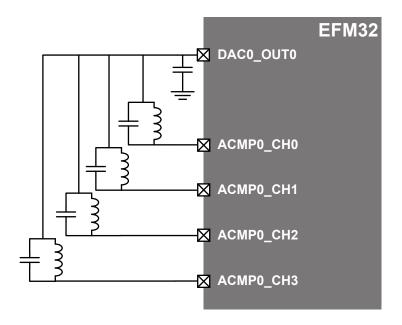

The following steps show how to configure LESENSE to scan through the four buttons 100 times per second, issuing an interrupt if one of them is pressed.

- 1. Assuming LFACLK<sub>LESENSE</sub> is 32kHz, set PCPRESC to 3 and PCTOP to 39 in CTRL. This will make the LESENSE scan frequency 100Hz.
- 2. Enable channels 0 through 3 in CHEN and set IDLECONF for these channels to DISABLED. In capacitive sense mode, the GPIO should always be disabled (analog input).
- 3. Configure the ACMP to operate in CAPSENSE mode, refer to 26.3.5 Capacitive Sense Mode for details.
- 4. Configure the following bit fields in CHx\_CONF, for channels 0 through 3:
  - a. Set EXTIME to 0. No excitation is needed in this mode.
  - b. Set SAMPLE to COUNTER and COMP to LESS. This makes LESENSE interpret a sensor as active if the frequency on a channel drops below the threshold, i.e. the button is pressed.
  - c. Set SAMPLEDLY to an appropriate value, each sensor will be measured for SAMPLEDLY/ LFACLK<sub>LESENSE</sub> seconds. MEAS-UREDLY should be set to 0
- 5. Set CTRTHRESHOLD to an appropriate value. An interrupt will be issued if the counter value for a sensor is below this threshold after the measurement phase.
- 6. Enable interrupts on channels 0 through 3.
- 7. Start scan sequence by writing a 1 to START in CMD.

In a capacitive sense application, it might be required to calibrate the threshold values on a periodic basis, this is done in order to compensate for humidity and other physical variations. LESENSE is able to store up to 16 counter values from a configurable number of channels, making it possible to collect sample data while in EM2. When calibration is to be performed, the CPU only has to be woken up for a short period of time as the data to be processed already lies in the result registers. To enable storing of the count value for a channel, set STRSAMPLE in the CHx\_INTERACT register.

### 25.3.14.2 LC Sensor

The following figure below illustrates how the EFM32WG can be set up to monitor four LC sensors.

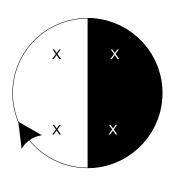

Figure 25.11. LC Sensor Setup

LESENSE can be used to excite and measure the damping factor in LC sensor oscillations. To measure the damping factor, the ACMP can be used to generate a high output each time the sensor voltage exceeds a certain level. These pulses are counted using an asynchronous counter and compared with the threshold in COMPTHRES in the CHx\_EVAL register. If the number of pulses exceeds the threshold level, the sensor is said to be active, otherwise it is inactive. The following figure illustrates how the output pulses from the ACMP correspond to damping of the oscillations. The results from sensor evaluation can automatically be fed into the decoder in order to keep track of rotations.

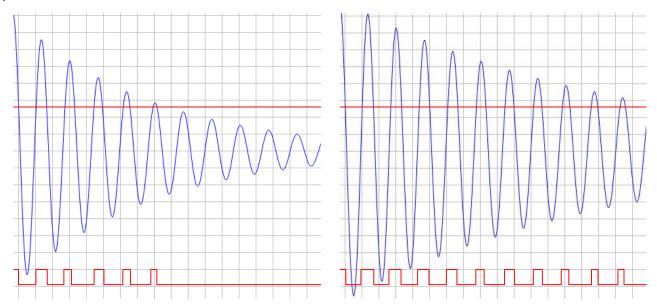

Figure 25.12. LC Sensor Oscillations

The following steps show how to configure LESENSE to scan through the four LC sensors 100 times per second.

- 1. Assuming LFACLK<sub>LESENSE</sub> is 32kHz, set PCPRESC to 3 and PCTOP to 39 in CTRL. This will make the LESENSE scan frequency 100Hz.
- 2. Enable the DAC and configure it to produce a voltage of Vdd/2.
- 3. Enable channels 0 through 3 in CHEN. Set IDLECONF for the active channels to DACOUT. The channel pins should be set to Vdd/2 in the idle phase to damp the oscillations.

- 4. Configure the ACMP to use scaled Vdd as negative input, refer to ACMP chapter for details.
- 5. Enable and configure PCNT and asynchronous PRS.
- 6. Configure the GPIOs used as PUSHPULL
- 7. Configure the following bit fields in CHx\_CONF, for channels 0 through 3:
  - a. Set EXCLK to AUXHFRCO. AUXHFRCO is needed to achieve short excitation time.
  - b. Set EXTIME to an appropriate value. Excitation will last for EXTIME/AUXHFRCO seconds (prescalar value in AUXPRESC in TIMCTRL is 0).
  - c. Set EXMODE to LOW. The LC sensors are excited by pulling the excitation pin low.
  - d. Set SAMPLE to COUNTER and COMP to LESS. Status of each sensor is evaluated based on the number of pulses generated by the ACMP. If they are less than the threshold value, the sensor is said to be active.
  - e. Set SAMPLEDLY to an appropriate value, each sensor will be measured for SAMPLEDLY/ LFACLK<sup>LESENSE</sup> seconds.
- 8. Set CTRTHRESHOLD to an appropriate value. If the sensor is active, the counter value after the measurement phase should be less than the threshold. If it inactive, the counter value should be greater than the threshold.
- 9. Start scan sequence by writing a 1 to START in CMD.

### 25.3.14.3 LESENSE Decoder 1

The example below illustrates how the LESENSE module can be used for decoding using three sensors.

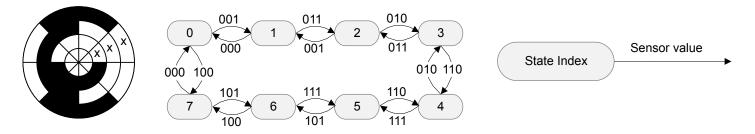

Figure 25.13. FSM Example 1

To set up the decoder to decode rotation using the encoding scheme seen in the previous figure, configure the following LESENSE registers:

- 1. Configure the channels to be used, be sure to set DECODE in CHx EVAL.
- 2. Set PRSCNT to enable generation of count waveforms on PRS. Also configure a PCNT to listen to the PRS channels and count accordingly.
- 3. Configure the following in STx\_TCONFA and STx\_TCONFB:
  - a. Set MASK = 0b1000 in STx\_TCONFA and STx\_TCONFB for all used states. This enables three sensors to be evaluated by the decoder.
  - b. Configure the remaining bit fields in STx\_TCONFA and STx\_TCONFB as described in the following table.

Register	TCON- FA_NEXT	TCAOTNE- FA_COMP	TCON- FA_PRSACT	TCONFB_NE XT	TTCAOT- NEFB_COMP	TCONFB_PR SACT
ST0	1	0b001	UP	7	0b100	DOWN
ST1	2	0b011	UP	0	0b000	DOWN
ST2	3	0b010	UP	1	0b001	DOWN
ST3	4	0b110	UP	2	0b011	DOWN
ST4	5	0b111	UP	3	0b010	DOWN
ST5	6	0b101	UP	4	0b110	DOWN
ST6	7	0b100	UP	5	0b111	DOWN
ST7	0	0b000	UP	6	0b101	DOWN

**Table 25.3. LESENSE Decoder Configuration** 

<sup>4.</sup> To initialize the decoder, run one scan, and read the present sensor status from SENSORSTATE. Then write the index of this state to DECSTATE.

<sup>5.</sup> Write to START in CMD to start scanning of sensors and decoding.

## 25.3.14.4 LESENSE Decoder 2

The example below illustrates how the LESENSE decoder can be used to implement the state machine seen in the following figure.

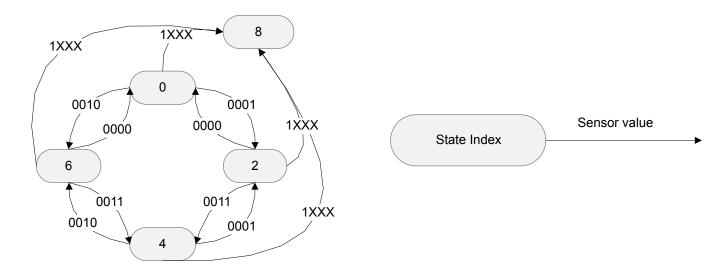

Figure 25.14. FSM Example 2

1. Configure STx\_TCONFA and STx\_TCONFB as described in the following table.

Table 25.4. LESENSE Decoder Configuration

Register	NEXTSTATE	COMP	MASK	CHAIN
ST0_TCONFA	8	0b1000	0b0111	1
ST0_TCONFB	2	0b0001	0b1000	_
ST1_TCONFA	6	0b0010	0b1000	0
ST1_TCONFB	6	0b0010	0b1000	-
ST2_TCONFA	8	0b1000	0b0111	1
ST2_TCONFB	4	0b0011	0b1000	-
ST3_TCONFA	0	0b0000	0b1000	0
ST3_TCONFB	0	0b0000	0b1000	-
ST4_TCONFA	8	0b1000	0b0111	1

<sup>2.</sup> To initialize the decoder, run one scan, and read the present sensor status from SENSORSTATE. Then write the index of this state to DECSTATE.

<sup>3.</sup> Write to START in CMD to start scanning of sensors and decoding.

Bit	Name Reset Access Description																														

Bit	Name	Reset	Access	Description						
31:23	Reserved	To ensure co	mpatibility (	with future devices, always write bits to 0. More information in 2.1 Conven-						
22	DEBUGRUN	0	RW	Debug Mode Run Enable						
	Set to keep LESEN	SE running in deb	oug mode.							
	Value			Description						
	0			LESENSE can not start new scans in debug mode						
	1			LESENSE can start new scans in debug mode						
21:20	DMAWU	0x0	RW	DMA wake-up from EM2						
	Value	Mode		Description						
	0	DISABLE		No DMA wake-up from EM2						
	1	BUFDATAV		DMA wake-up from EM2 when data is valid in the result buffer						
	2	BUFLEVEL		DMA wake-up from EM2 when the result buffer is full/half-full depending on BUFIDL configuration						
19	Reserved	To ensure co	mpatibility (	with future devices, always write bits to 0. More information in 2.1 Conven-						
18	BUFIDL	0	RW	Result buffer interrupt and DMA trigger level						
	Value	Mode		Description						
	0	HALFFULL		DMA and interrupt flags set when result buffer is half-full						
	1	FULL		DMA and interrupt flags set when result buffer is full						
17	STRSCANRES	0	RW	Enable storing of SCANRES						
	When set, SCANRE	ES will be stored i	n the result	buffer after each scan						

Bit	Name	Reset	Access	Description
16	BUFOW	0	RW	Result buffer overwrite
	If set, LESENSE will	always write to	the result b	uffer, even if it is full
15:14	Reserved	To ensure co tions.	mpatibility (	with future devices, always write bits to 0. More information in 2.1 Conven-
13	DUALSAMPLE	0	RW	Enable dual sample mode
	When set, both ACM	IPs will be samp	led simulta	neously.
12	Reserved	To ensure co tions.	mpatibility (	with future devices, always write bits to 0. More information in 2.1 Conven-
11	ALTEXMAP	0	RW	Alternative excitation map
	Value	Mode		Description
	0	ALTEX		Alternative excitation is mapped to the LES_ALTEX pins.
	1	ACMP		Alternative excitation is mapped to the pins of the other ACMP.
10	ACMP1INV	0	RW	Invert analog comparator 1 output
9	ACMP0INV	0	RW	Invert analog comparator 0 output
8	Reserved	To ensure co	mpatibility (	with future devices, always write bits to 0. More information in 2.1 Conven-
7:6	SCANCONF	0x0	RW	Select scan configuration
	These bits control wl	nich CHx_CONF	registers to	o be used.
	Value	Mode		Description
	0	DIRMAP		The channel configuration register registers used are directly mapped to the channel number.
	1	INVMAP		The channel configuration register registers used are $CH_{X+8}$ _CONF for channels 0-7 and $CH_{X-8}$ _CONF for channels 8-15.
	2	TOGGLE		The channel configuration register registers used toggles between $CH_{X}$ _CONF and $CH_{X+8}$ _CONF when channel x triggers
	3	DECDEF		The decoder state defines the CONF registers to be used.
5:2	PRSSEL	0x0	RW	Scan start PRS select
	Select PRS source for	or scan start if S	CANMODE	is set to PRS.
	Value	Mode		Description
	0	PRSCH0		PRS Channel 0 selected as input
	1	PRSCH1		PRS Channel 1 selected as input
	2	PRSCH2		PRS Channel 2 selected as input
	3	PRSCH3		PRS Channel 3 selected as input
	4	PRSCH4		PRS Channel 4 selected as input
	5	PRSCH5		PRS Channel 5 selected as input

Bit	Name	Reset	Access	Description						
	6	PRSCH6		PRS Channel 6 selected as input						
	7	PRSCH7		PRS Channel 7 selected as input						
	8	PRSCH8		PRS Channel 8 selected as input						
	9	PRSCH9		PRS Channel 9 selected as input						
	10	PRSCH10		PRS Channel 10 selected as input						
	11	PRSCH11		PRS Channel 11 selected as input						
:0	SCANMODE	0x0	RW	Configure scan mode						
	These bits control	how the scan frequ	ency is de	cided						
	Value	Mode		Description						
	0	PERIODIC		A new scan is started each time the period counter overflows						
	1	ONESHOT		A single scan is performed when START in CMD is set						
	2	PRS		Pulse on PRS channel

### 26. ACMP - Analog Comparator

#### **Quick Facts**

#### What?

The ACMP (Analog Comparator) compares two analog signals and returns a digital value telling which is greater.

#### Why?

Applications often do not need to know the exact value of an analog signal, only if it has passed a certain threshold. Often the voltage must be monitored continuously, which requires extremely low power consumption.

#### How?

Available down to Energy Mode 3 and using as little as 100 nA, the ACMP can wake up the system when input signals pass the threshold. The analog comparator can compare two analog signals or one analog signal and a highly configurable internal reference.

#### 26.1 Introduction

The Analog Comparator is used to compare the voltage of two analog inputs, with a digital output indicating which input voltage is higher. Inputs can either be one of the selectable internal references or from external pins. Response time and thereby also the current consumption can be configured by altering the current supply to the comparator.

#### 26.2 Features

- · 8 selectable external positive inputs
- · 8 selectable external negative inputs
- · 5 selectable internal negative inputs
  - Internal 1.25 V bandgap
  - Internal 2.5 V bandgap
  - V<sub>DD</sub> scaled by 64 selectable factors
  - · DAC channel 0 and 1
- Low power mode for internal V<sub>DD</sub> and bandgap references
- · Selectable hysteresis
  - 8 levels between 0 and ±70 mV
- Selectable response time
- · Asynchronous interrupt generation on selectable edges
  - · Rising edge
  - · Falling edge
  - · Both edges
- · Operational in EM0-EM3
- · Dedicated capacitive sense mode with up to 8 inputs
  - · Adjustable internal resistor
- · Configurable inversion of comparator output
- · Configurable output when inactive
- · Comparator output direct on PRS
- · Comparator output on GPIO through alternate functionality
  - · Output inversion available

#### 26.3 Functional Description

An overview of the ACMP is shown in the following figure.

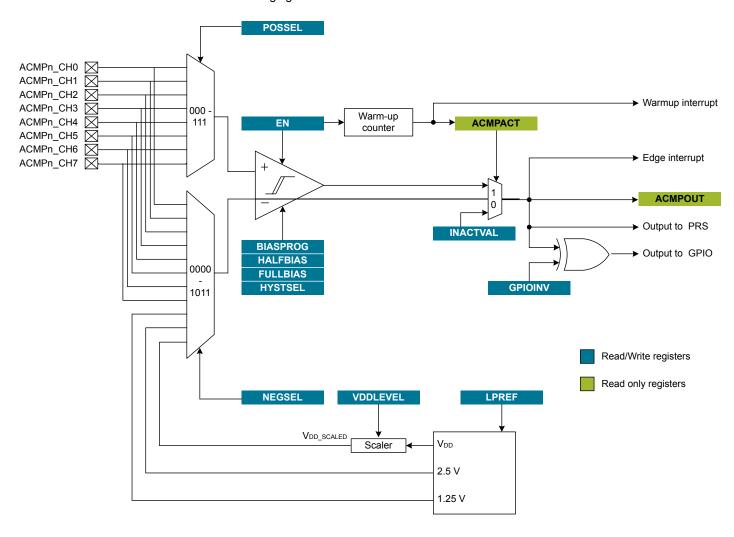

Figure 26.1. ACMP Overview

The comparator has two analog inputs, one positive and one negative. When the comparator is active, the output indicates which of the two input voltages is higher. When the voltage on the positive input is higher than the voltage on the negative input, the digital output is high and vice versa.

The output of the comparator can be read in the ACMPOUT bit in ACMPn\_STATUS. It is possible to switch inputs while the comparator is enabled, but all other configuration should only be changed while the comparator is disabled.

### 26.3.1 Warm-up Time

The analog comparator is enabled by setting the EN bit in ACMPn\_CTRL. When this bit is set, the comparator must stabilize before becoming active and the outputs can be used. This time period is called the warm-up time. The warm-up time is a configurable number of peripheral clock (HFPERCLK) cycles, set in WARMTIME, which should be set to at least 10 µs but lengthens to up to 1ms if LPREF is enabled. The ACMP should always start in active mode and then enable the LPREF after warm-up time. When the comparator is enabled and warmed up, the ACMPACT bit in ACMPn\_STATUS will indicate that the comparator is active. The output value when the comparator is inactive is set to the value in INACTVAL in ACMPn\_CTRL (see previous figure).

An edge interrupt will be generated after the warm-up time if edge interrupt is enabled and the value set in INACTVAL is different from ACMPOUT after warm-up.

One should wait until the warm-up period is over before entering EM2 or EM3, otherwise no comparator interrupts will be detected. EM1 can still be entered during warm-up. After the warm-up period is completed, interrupts will be detected in EM2 and EM3.

### 26.3.2 Response Time

There is a delay from when the actual input voltage changes polarity, to when the output toggles. This period is called the response time and can be altered by increasing or decreasing the bias current to the comparator through the BIASPROG, FULLBIASPROG and HALFBIAS fields in the ACMPn\_CTRL register, as illustrated in the following table. Setting the HALFBIAS bit in ACMPn\_CTRL effectively halves the current. Setting a lower bias current will result in lower power consumption, but a longer response time.

If the FULLBIAS bit is set, the highest hysteresis level should be used to avoid glitches on the output.

Table 26.1. Bias Configuration

BIASPROG	Bias Current (μA), HYSTSEI	_=0		
	FULLBIAS=0, HALFBIAS=1	FULLBIAS=0, HALFBIAS=0	FULLBIAS=1, HALFBIAS=1	FULLBIAS=1, HALFBIAS=0
0b0000	0.05	0.1	3.3	6.5
0b0001	0.1	0.2	6.5	13
0b0010	0.2	0.4	13	26
0b0011	0.3	0.6	20	39
0b0100	0.4	0.8	26	52
0b0101	0.5	1.0	33	65
0b0110	0.6	1.2	39	78
0b0111	0.7	1.4	46	91
0b1000	1.0	2.0	65	130
0b1001	1.1	2.2	72	143
0b1010	1.2	2.4	78	156
0b1011	1.3	2.6	85	169
0b1100	1.4	2.8	91	182
0b1101	1.5	3.0	98	195
0b1110	1.6	3.2	104	208
0b1111	1.7	3.4	111	221

#### 26.3.3 Hysteresis

In the analog comparator, hysteresis can be configured to 8 different levels, including off which is level 0, through the HYSTSEL field in ACMPn\_CTRL. When the hysteresis level is set above 0, the digital output will not toggle until the positive input voltage is at a voltage equal to the hysteresis level above or below the negative input voltage (see the following figure). This feature can be used to filter out uninteresting input fluctuations around zero and only show changes that are big enough to breach the hysteresis threshold. Note that the ACMP current consumption will be influenced by the selected hysteresis level and in general decrease with increasing HYSTSEL values.

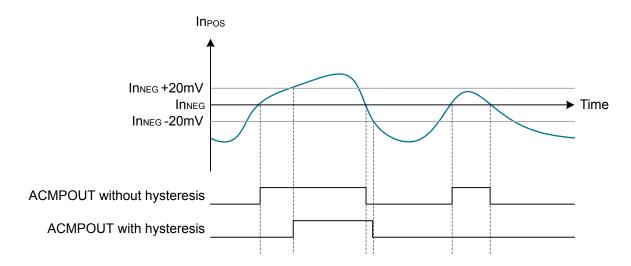

Figure 26.2. 20 mV Hysteresis Selected

#### 26.3.4 Input Selection

The POSSEL and NEGSEL fields in ACMPn\_INPUTSEL controls which signals are connected to the two inputs of the comparator. 8 external pins are available for both the negative and positive input. For the negative input, 5 additional internal reference sources are available; 1.25 V bandgap, 2.5V bandgap, DAC channel 0, DAC channel 1, and  $V_{DD}$ . The  $V_{DD}$  reference can be scaled by a configurable factor, which is set in VDDLEVEL (in ACMPn\_INPUTSEL) according to the following formula:

$$V_{\text{DD\_SCALED}} = V_{\text{DD}} \times \text{VDDLEVEL/63}$$

A low power reference mode can be enabled by setting the LPREF bit in ACMPn\_INPUTSEL. In this mode, the power consumption in the reference buffer ( $V_{DD}$  and bandgap) is lowered at the cost of accuracy. Low power mode will only save power if  $V_{DD}$  with VDDLE-VEL higher than 0 or a bandgap reference is selected.

Normally the analog comparator input mux is disabled when the EN (in ACMPn\_CTRL) bit is set low. However if the MUXEN bit in ACMPn\_CTRL is set, the mux is enabled regardless of the EN bit. This will minimize kickback noise on the mux inputs when the EN bit is toggled.

#### 26.3.5 Capacitive Sense Mode

The analog comparator includes specialized hardware for capacitive sensing of passive push buttons. Such buttons are traces on PCB laid out in a way that creates a parasitic capacitor between the button and the ground node. Because a human finger will have a small intrinsic capacitance to ground, the capacitance of the button will increase when the button is touched. The capacitance is measured by including the capacitor in a free-running RC oscillator (see the following figure). The frequency produced will decrease when the button is touched compared to when it is not touched. By measuring the output frequency with a timer (e.g. through PRS), the change in capacitance can be calculated.

The analog comparator contains a complete feedback loop including an optional internal resistor. This resistor is enabled by setting the CSRESEN bit in ACMPn\_INPUTSEL. The resistance can be set to one of four values by configuring the CSRESSEL bits in ACMPn\_INPUTSEL. If the internal resistor is not enabled, the circuit will be open. The capacitive sense mode is enabled by setting the NEGSEL field in ACMPn\_INPUTSEL to CAPSENSE. The input pin is selected through the POSSEL bits in ACMPn\_INPUTSEL. The scaled  $V_{DD}$  in the following figure can be altered by configuring the VDDLEVEL in ACMPn\_INPUTSEL. It is recommended to set the hysteresis (HYSTSEL in ACMPn\_CTRL) higher than the lowest level when using the analog comparator in capacitive sense mode.

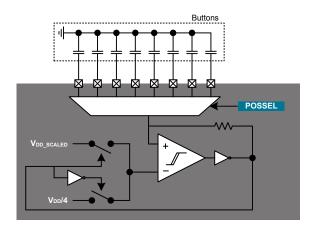

Figure 26.3. Capacitive Sensing Setup

#### 26.3.6 Interrupts and PRS Output

The analog comparator includes an edge triggered interrupt flag (EDGE in ACMPn\_IF). If either IRISE and/or IFALL in ACMPn\_CTRL is set, the EDGE interrupt flag will be set on rising and/or falling edge of the comparator output, respectively. An interrupt request will be sent if the EDGE interrupt flag in ACMPn\_IF is set and enabled through the EDGE bit in ACMPn\_IEN. The edge interrupt can also be used to wake up the device from EM3-EM1.

The analog comparator also includes an interrupt flag, WARMUP in ACMPn\_IF, which is set when a warm-up sequence has finished. An interrupt request will be sent if the WARMUP interrupt flag in ACMPn\_IF is set and enabled through the WARMUP bit in ACMPn IEN.

The comparator output is also available as a PRS signal.

#### 26.3.7 Output to GPIO

The output from the comparator is available as alternate function to the GPIO pins. Set the ACMPPEN bit in ACMPn\_ROUTE to enable output to pin, and the LOCATION bits to select output location. The GPIO-pin must also be set as output. The output to the GPIO can be inverted by setting the GPIOINV bit in ACMPn\_CTRL.

## 27. VCMP - Voltage Comparator

#### **Quick Facts**

#### What?

The Voltage Supply Comparator (VCMP) monitors the input voltage supply and generates software interrupts on events using as little as 100 nA.

#### Why?

The VCMP can be used for simple power supply monitoring, e.g. for a battery level indicator.

#### How?

The scaled power supply is compared to a programmable reference voltage, and an interrupt can be generated when the supply is higher or lower than the reference. The VCMP can also be duty-cycled by software to further reduce the energy consumption.

### 27.1 Introduction

The Voltage Supply Comparator is used to monitor the supply voltage from software. An interrupt can be generated when the supply falls below or rises above a programmable threshold.

**Note:** Note that VCMP comes in addition to the Power-on Reset and Brown-out Detector peripherals, that both generate reset signals when the voltage supply is insufficient for reliable operation. VCMP does not generate reset, only interrupt. Also note that the ADC is capable of sampling the input voltage supply.

## 27.2 Features

- Voltage supply monitoring
- Scalable V<sub>DD</sub> in 64 steps selectable as positive comparator input
- Internal 1.25 V bandgap reference
- Low power mode for internal V<sub>DD</sub> and bandgap references
- Selectable hysteresis (two settings)
- · Selectable response time
- Asynchronous interrupt generation on selectable edges
  - · Rising edge
  - · Falling edge
  - · Rising and Falling edges
- · Operational in EM0-EM3
- Comparator output direct on PRS
- · Configurable output when inactive to avoid unwanted interrupts

### 27.3 Functional Description

An overview of the VCMP is shown in the following figure.

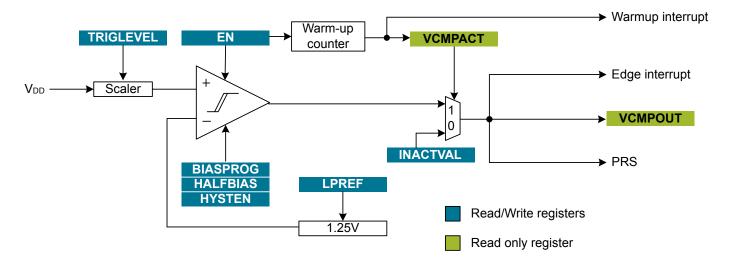

Figure 27.1. VCMP Overview

The comparator has two analog inputs, one positive and one negative. When the comparator is active, the output indicates which of the two input voltages is higher. When the voltage on the positive input is higher than the negative input voltage, the digital output is high and vice versa.

The output of the comparator can be read in the VCMPOUT bit in VCMP\_STATUS. Configuration registers should only be changed while the comparator is disabled.

### 27.3.1 Warm-Up Time

VCMP is enabled by setting the EN bit in VCMP\_CTRL. When this bit is set, the comparator must stabilize before becoming active and the outputs can be used. This time period is called the warm-up time. The warm-up time is a configurable number of HFPERCLK cycles, set in WARMTIME, which should be set to at least 10 µs. When the comparator is enabled and warmed up, the VCMPACT bit in VCMP\_STATUS will be set to indicate that the comparator is active.

As long as the comparator is not enabled or not warmed up, VCMPACT will be cleared and the comparator output value is set to the value in INACTVAL in VCMP\_CTRL.

One should wait until the warm-up period is over before entering EM2 or EM3, otherwise no comparator interrupts will be detected. EM1 can still be entered during warm-up. After the warm-up period is completed, interrupts will be detected in EM2 and EM3.

## 27.3.2 Response Time

There is a delay from when the actual input voltage changes polarity, to when the output toggles. This period is called the response time and can be altered by increasing or decreasing the bias current to the comparator through the BIAS and HALFBIAS fields in VCMP\_CTRL as shown in the following table. Setting a lower bias current will result in lower power consumption, but a longer response time.

Table 27.1. Bias Configuration

BIAS	Bias Current (μA)	
	HALFBIAS=0	HALFBIAS=1
0ь0000	0.1	0.05
0b0001	0.2	0.1
0b0010	0.4	0.2
0b0011	0.6	0.3
0b0100	0.8	0.4
0b0101	1.0	0.5
0b0110	1.2	0.6
0b0111	1.4	0.7
0b1000	2.0	1.0
0b1001	2.2	1.1
0b1010	2.4	1.2
0b1011	2.6	1.3
0b1100	2.8	1.4
0b1101	3.0	1.5
0b1110	3.2	1.6
0b1111	3.4	1.7

### 27.3.3 Hysteresis

In the voltage supply comparator, hysteresis can be enabled by setting HYSTEN in VCMP\_CTRL. When HYSTEN is set, the digital output will not toggle until the positive input voltage is some magnitude above or below the negative input voltage. This feature can be used to filter out uninteresting input fluctuations around zero and only show changes that are big enough to breach the hysteresis threshold.

See the specific device data sheet for more information on the magnitude of the hysteresis.

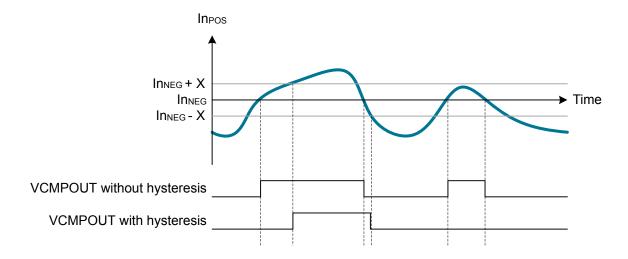

Figure 27.2. VCMP Hysteresis Enabled

#### 27.3.4 Input Selection

The positive comparator input is always connected to the scaled power supply input. The negative comparator input is connected to the internal 1.25 V bandgap reference. The  $V_{DD}$  trigger level can be configured by setting the TRIGLEVEL field in VCMP\_CTRL according to the following formula:

$$V_{\text{DD Trigger Level}} = 1.667V + 0.034V \times \text{TRIGLEVEL}$$

A low power reference mode can be enabled by setting the LPREF bit in VCMP\_INPUTSEL. In this mode, the power consumption in the reference buffer ( $V_{DD}$  and bandgap) is lowered at the cost of accuracy.

## 27.3.5 Interrupts and PRS Output

The VCMP includes an edge triggered interrupt flag (EDGE in VCMP\_IF). If either IRISE and/or IFALL in VCMPn\_CTRL is set, the EDGE interrupt flag will be set on rising and/or falling edge of the comparator output respectively. An interrupt request will be sent if the EDGE interrupt flag in VCMP\_IF is set and enabled through the EDGE bit in VCMPn\_IEN. The edge interrupt can also be used to wake up the device from EM3-EM1. VCMP also includes an interrupt flag, WARMUP in VCMP\_IF, which is set when a warm-up sequence has finished. An interrupt request will be sent if the WARMUP interrupt flag in VCMP\_IF is set and enabled through the WARMUP bit in VCMPn\_IEN. The synchronized comparator output is also available as a PRS output signal.

## 27.4 Register Map

The offset register address is relative to the registers base address.

## 28. ADC - Analog to Digital Converter

#### **Quick Facts**

#### What?

The ADC is used to convert analog signals into a digital representation and features 8 external input channels

### Why?

In many applications there is a need to measure analog signals and record them in a digital representation, without exhausting your energy source.

#### How?

A low power Successive Approximation Register ADC samples up to 8 input channels in a programmable sequence. With the help of PRS and DMA, the ADC can operate without CPU intervention, minimizing the number of powered up resources. The ADC can further be duty-cycled to reduce the energy consumption.

#### 28.1 Introduction

The ADC is a Successive Approximation Register (SAR) architecture, with a resolution of up to 12 bits at up to one million samples per second. The integrated input mux can select inputs from 8 external pins and 6 internal signals.

#### 28.2 Features

- Programmable resolution (6/8/12-bit)
  - 13 prescaled clock (ADC\_CLK) cycles per conversion
  - Maximum 1 MSPS @ 12-bit
  - · Maximum 1.86 MSPS @ 6-bit
- · Configurable acquisition time
- · Integrated prescaler
  - · Selectable clock division factor from 1 to 128
- · 13 MHz to 32 kHz allowed for ADC\_CLK
- 18 input channels
  - · 8 external single ended channels
  - · 6 internal single ended channels
    - · Including temperature sensor
  - · 4 external differential channels
- · Integrated input filter
  - · Low pass RC filter
  - · Decoupling capacitor
- · Left or right adjusted results
  - · Results in 2's complement representation
  - · Differential results sign extended to 32-bit results
- · Programmable scan sequence
  - · Up to 8 configurable samples in scan sequence
  - · Mask to select which pins are included in the sequence
  - · Triggered by software or PRS input
  - · One shot or repetitive mode
  - · Oversampling available
  - · Overflow interrupt flag set when overwriting unread results
  - · Conversion tailgating support for predictable periodic scans
- · Programmable single conversion
  - · Triggered by software or PRS input
  - · Can be interleaved between two scan sequences
  - · One shot or repetitive mode
  - · Oversampling available
  - Overflow interrupt flag set when overwriting unread results
- · Hardware oversampling support
  - · 1st order accumulate and dump filt
  - From 2 to 4096 oversampling ratio (OSR)
  - · Results in 16-bit representation
  - · Enabled individually for scan sequence and single sample mode
  - Common OSR select
- · Individually selectable voltage reference for scan and single mode
  - · Internal 1.25V reference
  - · Internal 2.5V reference
  - V<sub>DD</sub>
  - · Internal 5 V differential reference
  - · Single ended external reference
  - · Differential external reference
  - Unbuffered 2xV<sub>DD</sub>
- · Support for offset and gain calibration
- Interrupt generation and/or DMA request
  - · Finished single conversion
  - · Finished scan conversion

- · Single conversion results overflow
- · Scan sequence results overflow
- · Loopback configuration with DAC output measurement

### 28.3 Functional Description

An overview of the ADC is shown in the following figure.

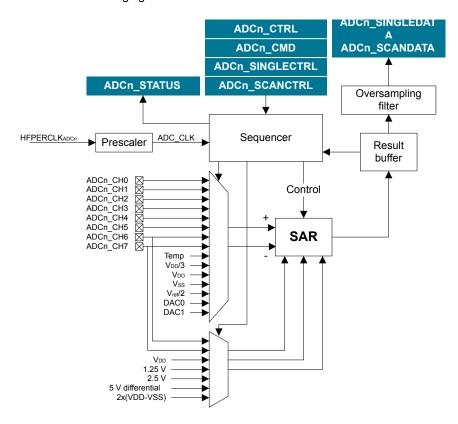

Figure 28.1. ADC Overview

### 28.3.1 Clock Selection

The ADC has an internal prescaler (PRESC bits in ADCn\_CTRL) which can divide the peripheral clock (HFPERCLK) by any factor between 1 and 128. Note that the resulting ADC\_CLK should not be set to a higher frequency than 13 MHz and not lower than 32 kHz.

#### 28.3.2 Conversions

A conversion consists of two phases. The input is sampled in the acquisition phase before it is converted to digital representation during the approximation phase. The acquisition time can be configured independently for scan and single conversions (see 28.3.7 ADC Modes) by setting AT in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. The acquisition times can be set to any integer power of 2 from 1 to 256 ADC CLK cycles.

**Note:** For high impedance sources the acquisition time should be adjusted to allow enough time for the internal sample capacitor to fully charge. The minimum acquisition time for the internal temperature sensor and  $V_{dd}/3$  is given in the electrical characteristics for the device.

The analog to digital converter core uses one clock cycle per output bit in the approximation phase.

$$T_{conv} = (T_A + N) \times OSR$$

T<sub>A</sub> equals the number of acquisition cycles and N is the resolution. OSR is the oversampling ratio (see 28.3.7.7 Oversampling ). The minimum conversion time is 7 ADC\_CYCLES with 6 bit resolution and 13 ADC\_CYCLES with 12 bit resolution. The maximum conversion time is 1097728 ADC CYCLES with the longest acquisition time, 12 bit resolution and highest oversampling rate.

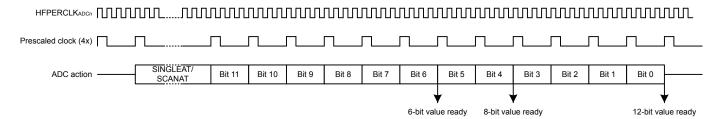

Figure 28.2. ADC Conversion Timing

### 28.3.3 Warm-Up Time

The ADC needs to be warmed up some time before a conversion can take place. This time period is called the warm-up time. When enabling the ADC or changing references between samples, the ADC is automatically warmed up for 1 µs and an additional 5 µs if the bandgap is selected as reference.

Normally, the ADC will be warmed up only when samples are requested and is shut off when there are no more samples waiting. However, if lower latency is needed, configuring the WARMUPMODE field in ADCn\_CTRL allows the ADC and/or reference to stay warm between samples, eliminating the need for warm-up. The following figure shows the analog power consumption in scenarios using the different WARMUPMODE settings.

Only the bandgap reference selected for scan mode can be kept warm. If a different bandgap reference is selected for single mode, the warm-up time still applies.

- NORMAL: ADC and references are shut off when there are no samples waiting. a) the following figure shows this mode used with an internal bandgap reference. Figure d) shows this mode when using VDD or an external reference.
- FASTBG: Bandgap warm-up is eliminated, but with reduced reference accuracy. d) the following figure shows this mode used with an internal bandgap reference.
- KEEPSCANREFWARM: The reference selected for scan mode is kept warm. The ADC will still need to be warmed up before conversion. b) the following figure shows this mode used with an internal bandgap reference.
- KEEPADCWARM: The ADC and the reference selected for scan mode is kept warm. c) the following figure shows this mode used with an internal bandgap reference.

The minimum warm-up times are given in  $\mu$ s. The timing is done automatically by the ADC, given that a proper time base is given in the TIMEBASE bits in ADCn\_CTRL. The TIMEBASE must be set to the number of HFPERCLK which corresponds to at least 1  $\mu$ s. The TIMEBASE only affects the timing of the warm-up sequence and not the ADC CLK.

When entering Energy Modes 2 or 3, the ADC must be stopped and WARMUPMODE in ADCn CTRL written to 0.

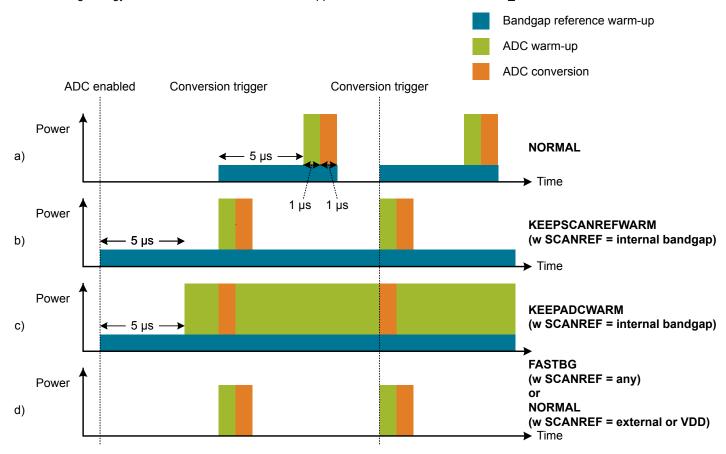

Figure 28.3. ADC Analog Power Consumption With Different WARMUPMODE Settings

### 28.3.4 Input Selection

The ADC is connected to 8 external input pins, which can be selected as 8 different single ended inputs or 4 differential inputs. In addition, 6 single ended internal inputs can be selected. The available selections are given in the register description for ADCn\_SIN-GLECTRL and ADCn\_SCANCTRL.

For offset calibration purposes it is possible to internally short the differential ADC inputs and thereby measure a 0 V differential. Differential 0 V is selected by writing the DIFF bit to 1 and INPUTSEL to 4 in ADCn\_SINGLECTRL. Calibration is described in detail in 28.3.10 Calibration.

**Note:** When VDD/3 is sampled, the acquisition time should be above a lower limit. The reader is referred to the datasheet for minimum VDD/3 acquisition time.

#### 28.3.4.1 Input Filtering

The selected input signal can be filtered, either through an internal low pass RC filter or an internal decoupling capacitor. The different filter configurations can be enabled through the LPFMODE bits in ADCn\_CTRL. For maximum SNR, LPFMODE is recommended set to DECAP, with a cutoff frequency of 31.5 MHz.

The RC input filter configuration is given in the following figure. The resistance and capacitance values are given in the electrical characteristics for the device, named  $R_{ADCFILT}$  and  $C_{ADCFILT}$  respectively.

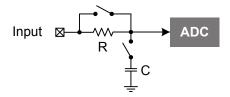

Figure 28.4. ADC RC Input Filter Configuration

### 28.3.4.2 Temperature Measurement

The ADC includes an internal temperature sensor. This sensor is characterized during production and the temperature readout from the ADC at production temperature, ADC0\_TEMP\_0\_READ\_1V25, is given in the Device Information (DI) page. The production temperature, CAL\_TEMP\_0, is also given in this page. The temperature gradient, TGRAD\_ADCTH (mV/degree Celsius), for the sensor is found in the datasheet for the devices. By selecting 1.25 V internal reference and measuring the internal temperature sensor with 12 bit resolution, the temperature can be calculated according to the following formula:

$$T_{\text{CELSIUS}} = \text{CAL\_TEMP\_0 - (ADC0\_TEMP\_0\_READ\_1V25 - ADC\_result)} \times \frac{\text{Vref}}{4096 \times \text{TGRAD\_ADCTH}}$$

Note: The minimum acquisition time for the temperature reference is found in the electrical characteristics for the device.

### 28.3.5 Reference Selection

The reference voltage can be selected from these sources:

- 1.25 V internal bandgap
- · 2.5 V internal bandgap
- V<sub>DD</sub>
- 5 V internal differential bandgap
- · External single ended input from Ch. 6
- Differential input, 2x(Ch. 6 Ch. 7)
- Unbuffered 2xV<sub>DD</sub>
- The 2.5 V reference needs a supply voltage higher than 2.5 V
- The differential 5 V reference needs a supply voltage higher than 2.75 V

Since the  $2xV_{DD}$  differential reference is unbuffered, it is directly connected to the ADC supply voltage and more susceptible to supply noise. The  $V_{DD}$  reference is buffered both in single ended and differential mode.

If a differential reference with a larger range than the supply voltage is combined with single ended measurements, for instance the 5 V internal reference, the full ADC range will not be available because the maximum input voltage is limited by the maximum electrical ratings.

Note: Single ended measurements with the external differential reference are not supported.

### 28.3.6 Programming of Bias Current

The bias current of the bandgap reference and the ADC comparator can be scaled by the BIASPROG, HALFBIAS and COMPBIAS bit fields of the ADCn\_BIASPROG register. The BIASPROG and HALFBIAS bitfields scale the current of ADC bandgap reference, and the COMPBIAS bits provide an additional bias programming for the ADC comparator as illustrated in the following figure. The electrical characteristics given in the datasheet require the bias configuration to be set to the default values, where no other bias values are given.

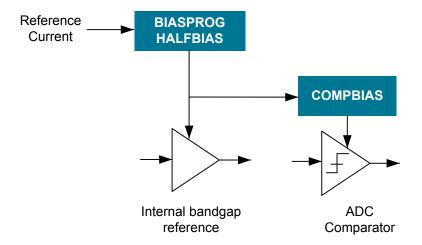

Figure 28.5. ADC Bias Programming

The minimum value of the BIASPROG and COMPBIAS bitfields of the ADCn\_BIASPROG register (i.e. BIASPROG=0b0000, COMP-BIAS=0b0000) represent the minimum bias currents. Similarly BIASPROG=0b1111 and COMPBIAS=0b1111 represent the maximum bias currents. Additionally, the bias current defined by the BIASPROG setting can be halved by setting the HALFBIAS bit of the ADCn\_BIASPROG register.

The bias current settings should only be changed while the ADC is disabled.

### 28.3.7 ADC Modes

The ADC contains two separate programmable modes, one single sample mode and one scan mode. Both modes have separate configuration and result registers and can be set up to run only once per trigger or repetitively. The scan mode has priority over the single sample mode. However, if scan sequence is running, a triggered single sample will be interleaved between two scan samples.

#### 28.3.7.1 Single Sample Mode

The single sample mode can be used to convert a single sample either once per trigger or repetitively. The configuration of the single sample mode is done in the ADCn\_SINGLECTRL register and the results are found in the ADCn\_SINGLEDATA register. The SINGLEDV bit in ADCn\_STATUS is set high when there is valid data in the result register and is cleared when the data is read. The single mode results can also be read through ADCn\_SINGLEDATAP without SINGLEDV being cleared. DIFF in ADCn\_SINGLECTRL selects whether differential or single ended inputs are used and INPUTSEL selects input pin(s).

#### 28.3.7.2 Scan Mode

The scan mode is used to perform sweeps of the inputs. The configuration of the scan sequence is done in the ADCn\_SCANCTRL register and the results are found in the ADCn\_SCANDATA register. The SCANDV bit in ADCn\_STATUS is set high when there is valid data in the result register and is cleared when the data is read. The scan mode results can also be read through ADCn\_SCANDATAP without SCANDV being cleared. The inputs included in the sequence are defined by a the mask in INPUTMASK in ADCn\_SCANCTRL. When the scan sequence is triggered, the sequence samples all inputs that are included in the mask, starting at the lowest pin number. DIFF in ADCn\_SCANCTRL selects whether single ended or differential inputs are used.

### 28.3.7.3 Conversion Tailgating

The scan sequence has priority over the single sample mode. However, a scan trigger will not interrupt in the middle of a single conversion. If a scan sequence is triggered by a timer on a periodic basis, single sample just before a scan trigger can delay the start of the scan sequence, thus causing jitter in sample rate. To solve this, conversion tailgating can be chosen by setting TAILGATE in ADCn\_CTRL. When this bit is set, any triggered single samples will wait for the next scan sequence to finish before activating (see the following figure). The single sample will then follow immediately after the scan sequence. In this way, the scan sequence will always start immediately when triggered, if the period between the scan triggers is big enough to allow any single samples that might be triggered to finish in between the scan sequences.

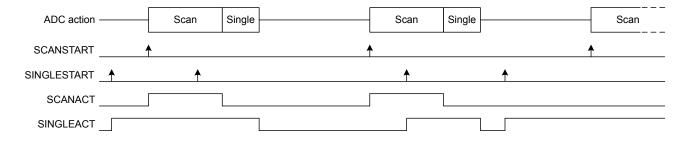

Figure 28.6. ADC Conversion Tailgating

### 28.3.7.4 Conversion Trigger

The conversion modes can be activated by writing a 1 to the SINGLESTART or SCANSTART bit in the ADCn\_CMD register. The conversions can be stopped by writing a 1 to the SINGLESTOP or SCANSTOP bit in the ADCn\_CMD register. A START command will have priority over a stop command. When the ADC is stopped in the middle of a conversion, the result buffer is cleared. The SINGLE-ACT and SCANACT bits in ADCn\_STATUS are set high when the modes are actively converting or have pending conversions.

It is also possible to trigger conversions from PRS signals. The system requires one HFPERCLK cycle pulses to trigger conversions. Setting PRSEN in ADCn\_SINGLECTRL/ADCn\_SCANCTRL enables triggering from PRS input. Which PRS channel to listen to is defined by PRSSEL in ADCn\_SINGLECTRL/ADCn\_SCANCTRL. When PRS trigger is selected, it is still possible to trigger the conversion from software. The reader is referred to the PRS datasheet for more information on how to set up the PRS channels.

Note: The conversion settings should not be changed while the ADC is running as this can lead to unpredictable behavior.

The prescaled clock phase is always reset by a triggered conversion as long as a conversion is not ongoing. This gives predictable latency from the time of the trigger to the time the conversion starts, regardless of when in the prescaled clock cycle the trigger occur.

### 28.3.7.5 Results

The results are presented in 2's complement form and the format for differential and single ended mode is given in the following tables. If differential mode is selected, the results are sign extended up to 32-bit (shown in Table 28.4 ADC Results Representation on page 890).

Table 28.1. ADC Single Ended Conversion

Input/Reference	Results								
	Binary	Hex Value							
1	11111111111	FFF							
0.5	01111111111	7FF							
1/4096	0000000001	001							
0	0000000000	000							

Table 28.2. ADC Differential Conversion

Input/Reference	Results	
	Binary	Hex Value
0.5	01111111111	7FF
0.25	00111111111	3FF
1/2048	00000000001	001
0	00000000000	000
-1/2048	11111111111	FFF
-0.25	10111111111	BFF
-0.5	10000000000	800

### 28.3.7.6 Resolution

The ADC gives out 12-bit results, by default. However, if full 12-bit resolution is not needed, it is possible to speed up the conversion by selecting a lower resolution (N = 6 or 8 bits). For more information on the accuracy of the ADC, the reader is referred to the electrical characteristics section for the device.

## 28.3.7.7 Oversampling

To achieve higher accuracy, hardware oversampling can be enabled individually for each mode (Set RES in ADCn\_SINGLECTRL/ ADCn\_SCANCTRL to 0x3). The oversampling rate (OVSRSEL in ADCn\_CTRL) can be set to any integer power of 2 from 2 to 4096 and the configuration is shared between the scan and single sample mode (OVSRSEL field in ADCn\_CTRL).

With oversampling, each selected input is sampled a number (given by the OVSR) of times, and the results are filtered by a first order accumulate and dump filter to form the end result. The data presented in the ADCn\_SINGLEDATA and ADCn\_SCANDATA registers are the direct contents of the accumulation register (sum of samples). However, if the oversampling ratio is set higher than 16x, the accumulated results are shifted to fit the MSB in bit 15 as shown in the following table.

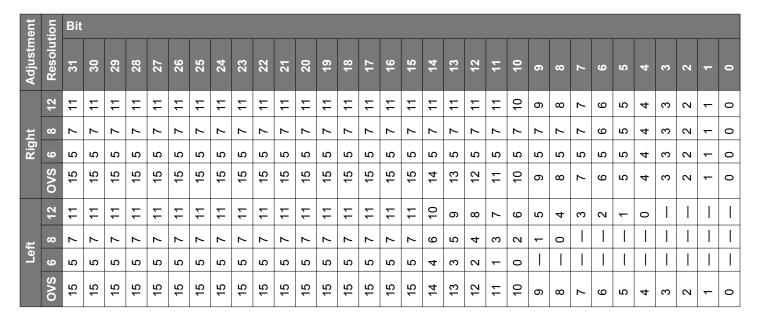

Table 28.3. Oversampling Result Shifting and Resolution

Oversampling Setting	# Right Shifts	Result Resolution # Bits
2x	0	13
4x	0	14
8x	0	15
16x	0	16
32x	1	16
64x	2	16
128x	3	16
256x	4	16
512x	5	16
1024x	6	16
2048x	7	16
4096x	8	16

### 28.3.7.8 Adjustment

By default, all results are right adjusted, with the LSB of the result in bit position 0 (zero). In differential mode the signed bit is extended up to bit 31, but in single ended mode the bits above the result are read as 0. By setting ADJ in ADCn\_SINGLECTRL/ADCn\_SCANCTRL, the results are left adjusted as shown in the table below. When left adjusted, the MSB is always placed on bit 15 and sign extended to bit 31. All bits below the conversion result are read as 0 (zero).

Table 28.4. ADC Results Representation

## 28.3.8 Interrupts, PRS Output

The single and scan modes have separate interrupt flags indicating finished conversions. Setting one of these flags will result in an ADC interrupt if the corresponding interrupt enable bit is set in ADCn IEN.

In addition to the finished conversion flags, there is a scan and single sample result overflow flag which signalizes that a result from a scan sequence or single sample has been overwritten before being read.

A finished conversion will result in a one HFPERCLK cycle pulse which is output to the Peripheral Reflex System (PRS).

## 28.3.9 DMA Request

The ADC has two DMA request lines, SINGLE and SCAN, which are set when a single or scan conversion has completed. The request are cleared when the corresponding single or scan result register is read.

#### 28.3.10 Calibration

The ADC supports offset and gain calibration to correct errors due to process and temperature variations. This must be done individually for each reference used. The ADC calibration (ADCn\_CAL) register contains four register fields for calibrating offset and gain for both single and scan mode. The gain and offset calibration are done in single mode, but the resulting calibration values can be used for both single and scan mode.

Gain and offset for the 1V25, 2V5 and VDD references are calibrated during production and the calibration values for these can be found in the Device Information page. During reset, the gain and offset calibration registers are loaded with the production calibration values for the 1V25 reference.

The SCANGAIN and SINGLEGAIN calibration fields are not used when the unbuffered differential 2xVDD reference is selected.

The effects of changing the calibration register values are given in the following table. Step by step calibration procedures for offset and gain are given in 28.3.10.1 Offset Calibration and 28.3.10.2 Gain Calibration.

Table 28.5. Calibration Register Effect

Calibration Register	ADC Result	Calibration Binary Value	Calibration Hex Value
Offset	Lowest Output	0111111	3F
	Highest Output	1000000	40
Gain	Lowest Output	0000000	00
	Highest Output	1111111	7F

The offset calibration register expects a signed 2's complement value with negative effect. A high value gives a low ADC reading.

The gain calibration register expects an unsigned value with positive effect. A high value gives a high ADC reading.

#### 28.3.10.1 Offset Calibration

Offset calibration must be performed prior to gain calibration. Follow these steps for the offset calibration in single mode:

- Select wanted reference by setting the REF bitfield of the ADCn\_SINGLECTRL register.
- 2. Set the AT bitfield of the ADCn\_SINGLECTRL register to 16CYCLES.
- 3. Set the INPUTSEL bitfield of the ADCn\_SINGLECTRL register to DIFF0, and set the DIFF bitfield to 1 for enabling differential input. Since the input voltage is 0, the expected ADC output is the half of the ADC code range as it is in differential mode.
- 4. A binary search is used to find the offset calibration value. Set the SINGLESTART bit in the ADCn\_CMD register and read the ADCn\_SINGLEDATA register. The result of the binary search is written to the SINGLEOFFSET field of the ADCn\_CAL register.

#### 28.3.10.2 Gain Calibration

Offset calibration must be performed prior to gain calibration. The Gain Calibration is done in the following manner:

- 1. Select an external ADC channel (a differential channel can also be used).
- 2. Apply an external voltage on the selected ADC input channel. This voltage should correspond to the top of the ADC range.
- 3. A binary search is used to find the gain calibration value. Set the SINGLESTART bit in the ADCn\_CTRL register and read the ADCn\_SINGLEDATA register. The target value is ideally the top of the ADC range, but it is recommended to use a value a couple of LSBs below in order to avoid overshooting. The result of the binary search is written to the SINGLEGAIN field of the ADCn\_CAL register.

## 28.4 Register Map

The offset register address is relative to the registers base address.

Offset	Name	Туре	Description
0x000	ADCn_CTRL	RW	Control Register

This register contains the offset calibration value used with single conversions. This field is set to the production offset calibration value for the 1V25 internal reference during reset, hence the reset value might differ from device to device. The field is encoded as a signed 2's complement number. Higher values lead to lower ADC results.

### 29. DAC - Digital to Analog Converter

#### **Quick Facts**

#### What?

The DAC is designed for low energy consumption, but can also provide very good performance. It can convert digital values to analog signals at up to 500 kilo samples/ second and with 12-bit accuracy.

#### Why?

The DAC is able to generate accurate analog signals using only a limited amount of energy.

#### How?

The DAC can generate high-resolution analog signals while the MCU is operating at low frequencies and with low total power consumption. Using DMA and a timer, the DAC can be used to generate waveforms without any CPU intervention.

#### 29.1 Introduction

The Digital to Analog Converter (DAC) can convert a digital value to an analog output voltage. The DAC is fully differential rail-to-rail, with 12-bit resolution. It has two single ended output buffers which can be combined into one differential output. The DAC may be used for a number of different applications such as sensor interfaces or sound output.

#### 29.2 Features

- 500 ksamples/s operation
- · Two single ended output channels
  - · Can be combined into one differential output
- Integrated prescaler with division factor selectable between 1-128
- · Selectable voltage reference
  - Internal 2.5V
  - Internal 1.25V
  - V<sub>DD</sub>
- · Conversion triggers
  - · Data write
  - · PRS input
- · Automatic refresh timer
  - · Selection from 16-64 prescaled HFPERCLK cycles
  - · Individual refresh enable for each channel
- · Interrupt generation on finished conversion
  - · Separate interrupt flag for each channel
- · PRS output pulse on finished conversion
  - · Separate line for each channel
- · DMA request on finished conversion
  - · Separate request for each channel
- · Support for offset and gain calibration
- Output to ADC
- · Sine generation mode
- · Optional high strength line driver

#### 29.3 Functional Description

An overview of the DAC module is shown in the following figure.

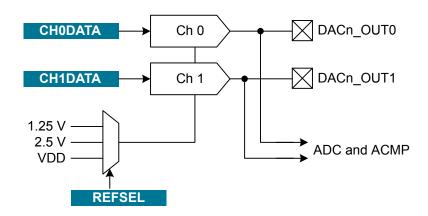

Figure 29.1. DAC Overview

#### 29.3.1 Conversions

The DAC consists of two channels (Channel 0 and 1) with separate 12-bit data registers (DACn\_CH0DATA and DACn\_CH1DATA). These can be used to produce two independent single ended outputs or the channel 0 register can be used to drive both outputs in differential mode. The DAC supports three conversion modes, continuous, sample/hold, sample/off.

#### 29.3.1.1 Continuous Mode

In continuous mode the DAC channels will drive their outputs continuously with the data in the DACn\_CHxDATA registers. This mode will maintain the output voltage and refresh is therefore not needed.

### 29.3.1.2 Sample/Hold Mode

In sample/hold mode, the DAC core converts data on a triggered conversion and then holds the output in a sample/hold element. When not converting, the DAC core is turned off between samples, which reduces the power consumption. Because of output voltage drift the sample/hold element will only hold the output for a certain period without a refresh conversion. The reader is referred to the electrical characteristics for the details on the voltage drift. The sampling period in this mode is set to the length of one prescaled clock cycle.

### 29.3.1.3 Sample/Off Mode

In sample/off mode the DAC and the sample/hold element is turned completely off between samples, tri-stating the DAC output. This requires the DAC output voltage to be held externally. The references are also turned off between samples, which means that a new warm-up period is needed before each conversion. The sampling period in this mode is set to the length of one prescaled clock cycle.

#### 29.3.1.4 Conversion Start

The DAC channel must be enabled before it can be used. When the channel is enabled, a conversion can be started by writing to the DACn\_CHxDATA register. These data registers are also mapped into a combined data register, DACn\_COMBDATA, where the data values for both channels can be written simultaneously. Writing to this register will start all enabled channels.

If the PRSEN bit in DACn\_CHxCTRL is set, a DAC conversion on channel x will not be started by data write, but when a positive one HFPERCLK cycle pulse is received on the PRS input selected by PRSSEL in DACn\_CHxCTRL.

The CH0DV and CH1DV bits in DACn STATUS indicate that the corresponding channel contains data that has not yet been converted.

When entering Energy Mode 4, both DAC channels must be stopped.

### 29.3.1.5 Clock Prescaling

The DAC has an internal clock prescaler, which can divide the HFPERCLK by any factor between 1 and 128, by setting the PRESC bits in DACnCTRL. The resulting DAC\_CLK is used by the converter core and the frequency is given by the following equation:

$$f_{\text{DAC\_CLK}} = \frac{f_{\text{HFPERCLK}}}{2^{\text{PRESC}}}$$

where f<sub>HFPERCLK</sub> is the HFPERCLK frequency. One conversion takes 2 DAC\_CLK cycles and the DAC\_CLK should not be set higher than 1 MHz.

Normally the PRESCALER runs continuously when either of the channels are enabled. When running with a prescaler setting higher than 0, there will be an unpredictable delay from the time the conversion was triggered to the time the actual conversion takes place. This is because the conversions is controlled by the prescaled clock and the conversion can arrive at any time during a prescaled clock (DAC\_CLK) period. However, if the CH0PRESCRST bit in DACn\_CTRL is set, the prescaler will be reset every time a conversion is triggered on channel 0. This leads to a predictable latency between channel 0 trigger and conversion.

#### 29.3.2 Reference Selection

Three internal voltage references are available and are selected by setting the REFSEL bits in DACn\_CTRL:

- · Internal 2.5V
- Internal 1.25V
- V<sub>DD</sub>

The reference selection can only be changed while both channels are disabled. The references for the DAC need to be enabled for some time before they can be used. This is called the warm-up period, and starts when one of the channels is enabled. For a bandgap reference, this period is 5 DAC\_CLK cycles while the V<sub>DD</sub> reference needs 1 DAC\_CLK cycle. The DAC will time this period automatically (given that the prescaler is set correctly) and delay any conversion triggers received during the warm-up until the references have stabilized.

### 29.3.3 Programming of Bias Current

The bias current of the bandgap reference and the DAC output buffer can be scaled by the BIASPROG and HALFBIAS bit fields of the DACn BIASPROG register as illustrated in the following figure.

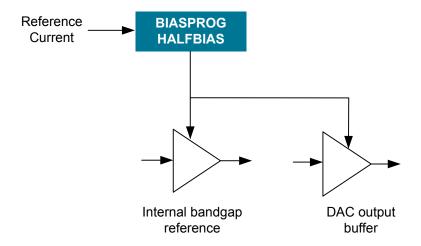

Figure 29.2. DAC Bias Programming

The minimum value of the BIASPROG bit-field of the DACn\_BIASPROG register (i.e. BIASPROG=0b0000) represents the minimum bias current. Similarly BIASPROG=0b1111 represents the maximum bias current. The bias current defined by the BIASPROG setting can be halved by setting the HALFBIAS bit of the DACn\_BIASPROG register.

The bias current settings should only be changed while both DAC channels are disabled. The electrical characteristics given in the datasheet require the bias configuration to be set to the default values, where no other bias values are given.

#### 29.3.4 Mode

The two DAC channels can act as two separate single ended channels or be combined into one differential channel. This is selected through the DIFF bit in DACn\_CTRL.

### 29.3.4.1 Single Ended Output

When operating in single ended mode, the channel 0 output is on DACn\_OUT0 and the channel 1 output is on DACn\_OUT1. The output voltage can be calculated using the following equation.

$$V_{\text{OUT}} = V_{\text{DACn\_OUTx}} - V_{\text{SS}} = V_{\text{ref}} \times \frac{\text{CHxDATA}}{4095}$$

where CHxDATA is a 12-bit unsigned integer.

### 29.3.4.2 Differential Output

When operating in differential mode, both DAC outputs are used as output for the bipolar voltage. The differential conversion uses DACn\_CHODATA as source. The positive output is on DACn\_OUT1 and the negative output is on DACn\_OUT0. Since the output can be negative, it is expected that the data is written in 2's complement form with the MSB of the 12-bit value being the signed bit. The output voltage can be calculated using the following equation:

$$V_{\text{OUT}} = V_{\text{DACn\_OUT1}} - V_{\text{DACn\_OUT0}} = V_{\text{ref}} \times \frac{\text{CH0DATA}}{2047}$$

where CH0DATA is a 12-bit signed integer. The common mode voltage is V<sub>DD</sub>/2.

#### 29.3.5 Sine Generation Mode

The DAC contains an automatic sine-generation mode, which is enabled by setting the SINEMODE bit in DACn\_CTRL. In this mode, the DAC data is overridden with a conversion data taken from a sine lookup table. The sine signal is controlled by the PRS line selected by CH0PRSSEL in DACn\_CH0CTRL. When the PRS line is low, a voltage of Vref/2 will be produced. When the line is high, a sine wave will be produced. Each period, starting at 0 degrees, is made up of 16 samples and the frequency is given by the following equation:

$$f_{\text{sine}} = \frac{f_{\text{HFPERCLK}}}{32} \times (\text{PRESC} + 1)$$

The SINE wave will be output on channel 0. If DIFF is set in DACn\_CTRL, the sine wave will be output on both channels (if enabled), but inverted (see the following figure). Note that when OUTENPRS in DACn\_CTRL is set, the sine output will be reset to 0 degrees when the PRS line selected by CH1PRSSEL is low.

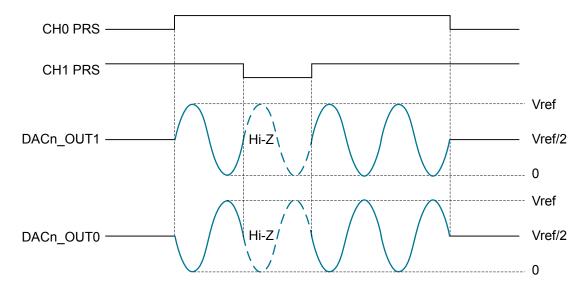

Figure 29.3. DAC Sine Mode

#### 29.3.6 Interrupts and PRS Output

Both DAC channels have separate interrupt flags (in DACn\_IF) indicating that a conversion has finished on the channel and that new data can be written to the data registers. Setting one of these flags will result in a DAC interrupt if the corresponding interrupt enable bit is set in DACn\_IEN. All generated interrupts from the DAC will activate the same interrupt vector when enabled.

The DAC has two PRS outputs which will carry a one cycle (HFPERCLK) high pulse when the corresponding channel has finished a conversion.

#### 29.3.7 DMA Request

The DAC sends out a DMA request when a conversion on a channel is complete. This request is cleared when the corresponding channel's data register is written.

#### 29.3.8 Analog Output

Each DAC channel has its own output pin (DACn\_OUT0 and DACn\_OUT1) in addition to an internal loopback to the ADC and ACMP. These outputs can be enabled and disabled individually in the EN field in DACn\_CHxCTRL registers in combination with OUTPUTSEL in DACn\_CTRL. The DAC outputs can also be directed to the ADC and ACMP, which is also configurable in the OUTPUTSEL field in DACn\_CTRL.

The DAC outputs are tri-stated when the channels are not enabled. By setting the OUTENPRS bit in DACn\_CTRL, the outputs are also tri-stated when the PRS line selected by CH1PRSSEL in DACn\_CH1CTRL is low. When the PRS signal is high, the outputs are enabled as normal.

The DAC channels can also drive an alternative output network, which is described in the Opamp chapter in 30.3.1.2 Output Configuration. To enable this network, OUTMODE must be configured to ADC in DACn\_CTRL. The actual output network can be configured by configuring DACn\_OPAxMUX registers.

#### 29.3.9 Calibration

The DAC contains a calibration register, DACn\_CAL, where calibration values for both offset and gain correction can be written. Offset calibration is done separately for each channel through the CHxOFFSET bit-fields. Gain is calibrated in one common register field, GAIN. The gain calibration is linked to the reference and when the reference is changed, the gain must be re-calibrated. Gain and offset for the 1V25, 2V5 and VDD references are calibrated during production and the calibration values for these can be found in the Device Information page. During reset, the gain and offset calibration registers are loaded with the production calibration values for the 1V25 reference.

### 29.3.10 Opamps

The DAC includes a set of three highly configurable opamps that can be accessed in the DAC module. Two of the opamps are located in the DAC, while the third opamp is a standalone opamp. For detailed description see the OPAMP chapter. The register description can be found in Register Description section of this chapter.

## 29.4 Register Map

### 30. OPAMP - Operational Amplifier

#### **Quick Facts**

#### What?

The opamps are low power amplifiers with a high degree of flexibility targeting a wide variety of standard opamp application areas. With flexible gain and interconnection builtin programming they can be configured to support multiple common opamp functions, with all pins available externally for filter configurations. Each opamp has a rail to rail input and a rail to rail output.

### Why?

The opamps are included to save energy on a pcb compared to standalone opamps, but also reduce system cost by replacing external opamps.

#### How?

Two of the opamps are made available as part of the DAC, while the third opamp is standalone. An ADC unity gain buffer mode configuration makes it possible to isolate kickback noise, in addition to popular differential to single ended and differential to differential driver modes. The opamps can also be configured as a one, two- or three-step cascaded PGA, and for all of the built-in modes no external components are necessary.

#### 30.1 Introduction

The opamps are highly configurable general purpose opamps, suitable for simple filters and buffer applications. The three opamps can be configured to support various operational amplifier functions through a network of muxes, with possibilities of selecting ranges of onchip non-inverting and inverting gain configurations, and selecting between outputs to various destinations. The opamps can also be configured with external feedback in addition to supporting cascade connections between two or three opamps. The opamps are rail-to-rail in and out. A user selectable mode has been added to optimize linearity, in which case the input voltage to the opamp is restricted between VSS and VDD-1.2V.

#### 30.2 Features

- · 3 individually configurable opamps
- · Opamps support rail-to-rail inputs and outputs
- · Supports the following functions
  - · General Opamp Mode
  - · Voltage Follower Unity Gain
  - · Inverting Input PGA
  - · Non-inverting PGA
  - · Cascaded Inverting PGA
  - · Cascaded Non-inverting PGA
  - · Two Opamp Differential Amplifier
  - · Three Opamp Differential Amplifier
  - · Dual Buffer ADC Driver
- · Programmable gain

#### 30.3 Functional Description

The three opamps can be configured to perform various opamp functions through a network of muxes. An overview of the opamps are shown in the following figure. Two of the three opamps are part of the DAC, while the third opamp is standalone. The output of OPA0 can be routed to ADC CH0, OPA1 and various pin outputs. The output of OPA1 can be routed to ADC CH1, OPA2, and various pin outputs. The output of OPA2 can be routed to ADC CH0, CH5, and various pin output destinations. All three opamps can also take input from pins. Since OPA0 and OPA1 are part of the DAC, special considerations needs to be taken when both the DAC Ch0/Ch1 and OPA0/OPA1 are being used. For detailed explanation the reader is referred to 30.3.3 Opamp DAC Combination.

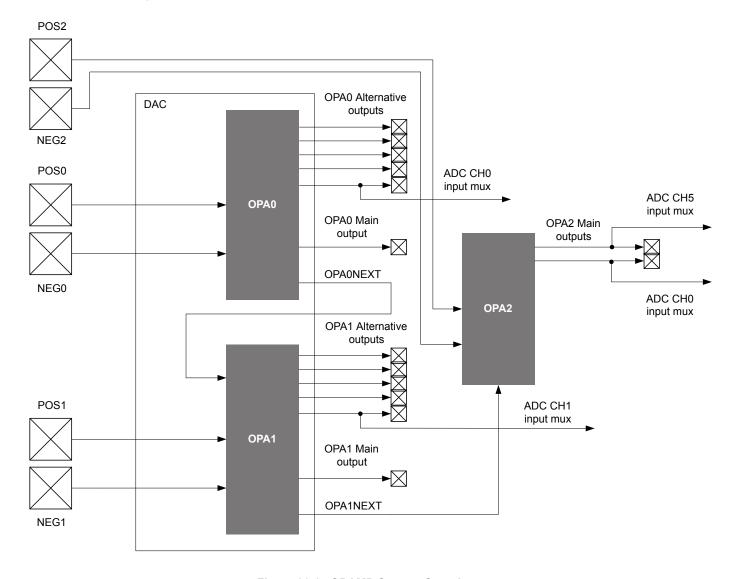

Figure 30.1. OPAMP System Overview

A more detailed view of the three opamps, including the mux network is shown in the following figure. There is a set of input muxes for each opamp, making it possible to select various input sources. The POSSEL mux connected to the positive input makes it possible to select pin, another opamp output, or tap from the resistor network. Similarly, the NEGSEL mux on the negative input makes it possible to select pin or a feedback path as its source. The feedback path can be a unity gain configuration, or selected from the resistor network for programmable gain. The output of the opamp have different sets of outputs, a main output, an alternative output network and a next output. These outputs make it possible to route the output to pin, another opamp input, ADC, or into the feedback path. For details regarding configuring the outputs, the reader is referred to 30.3.1.2 Output Configuration. In addition, there is also a mux to configure the resistor ladder to be connected to vss, pin, or another opamp output.

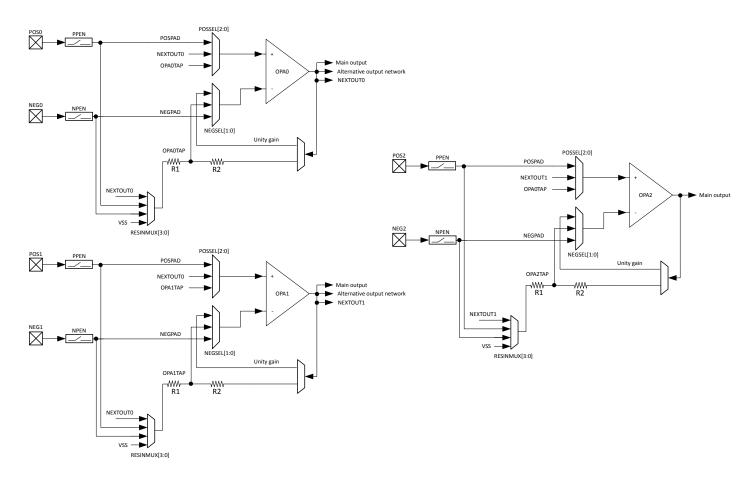

Figure 30.2. OPAMP Overview

### 30.3.1 Opamp Configuration

Since two of the three opamps (OPA0, OPA1) are part of the DAC, the opamp configuration registers are located in the DAC. The mux registers for OPA0/OPA1 together with OPA2 registers are separate registers, also located under the DAC module. OPA0 and OPA1 can be enabled by setting OPAxEN in DACn\_OPACTRL and CHxEN in CHxCTRL. OPA2 can be enabled by only setting OPA2EN in DACn\_OPACTRL.

#### 30.3.1.1 Input Configuration

The inputs to the opamps are controlled through a set of input muxes. The mux connected to the positive input is configured by the POSSEL bit-field in the DACn\_OPAxMUX register. Similarly, the mux connected to the negative input is configured by setting the NEGSEL bit-field in DACn\_OPAxMUX. To connect the pins to the input muxes, the pin switches must also be enabled. Setting the PPEN bitfield enables to POSPADx, while setting the NPEN bit-field enables the NEGPADx, both located in DACn\_OPAxMUX. The input into the resistor ladder can be configured by setting the RESINMUX bitfield in DACn\_OPAxMUX.

#### 30.3.1.2 Output Configuration

The opamp have two outputs, one main output and one alternative output with lower drive strength. These two outputs can be used to drive the different outputs as shown in the following figure. The main opamp output can be used to drive the main output by setting OUTMODE to MAIN in DACn\_OPAxMUX. The alternative opamp output can drive the alternative output network by setting OUTMODE to ALT in DACn\_OPAxMUX. In addition, it is also possible to use the main opamp output to drive both the main output and the alternative output network by setting OUTMODE to ALL in DACn\_OPAxMUX.

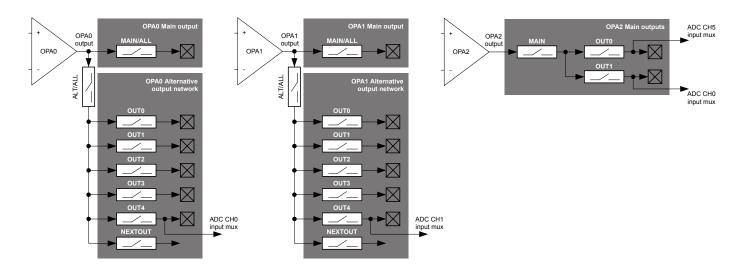

Figure 30.3. Opamp Output State Overview

The alternative output network consists of connections to pins, ADC, and a connection to the next opamp (OPA0 to OPA1, and OPA1 to OPA2). The connections to pins can be individually enabled by configuring OUTPEN in DACn\_OPAxMUX register. To enable cascaded opamp configurations, each opamp has a NEXTOUT connection. This output makes it possible to connect OPA0 to OPA1, and OPA1 to OPA2. This output connection is enabled by setting NEXTOUT in DACn\_OPAxMUX.

The opamps can also be routed to the ADC. OPA0 can be connected to ADC CH0, OPA1 to ADC CH1 and OPA2 can be connected to both ADC CH1 and CH5. The ADC connections are created by routing the OPA output by setting corresponding bits in OUTPEN in DACn\_OPAxMUX. For OPA0 alternative output 4 is connected to ADC input mux CH0 when enabled. OPA1's alternative output 4 is connected to ADC input mux CH1 when enabled. For OPA2, the two main outputs can be connected to ADC input mux CH0 and ADC input mux CH5 respectively when enabled. See 28.3.4 Input Selection, in the ADC chapter for information on how to configure the ADC input mux.

### 30.3.1.3 Gain Programming

The feedback path of each mux includes a resistor ladder, which can be used to select a set of gain values. The gain can be selected by the RESSEL bit-field located in DACn\_OPAxMUX register. The gain values are taken from tappings of the resistor ladder based on ratio of R2/R1. It is also possible to bypass the resistor ladder in Unity Gain (UG) mode.

### 30.3.1.4 Offset Calibration

The offset calibration registers are located in different registers for the opamps. OPA0 and OPA1's offset can be set through the CH0OFFSET and CH1OFFSET bit-fields respectively in DACn\_CAL. The offset for OPA2 can be set through OPA2OFFSET in DACn\_OPA0FFSET.

#### 30.3.1.5 Shorting Non-Inverting and Inverting Input

Functionality for offset calibration of the opamps has been added, this functionality is enabled by setting the OPAxSHORT bit-field in DACn\_OPAxCTRL. Setting this bit-field enables a switch that shorts between the inverting and non-inverting input of the OPA, effectively driving the offset voltage of the opamp to the output. Using the ADC to measure this offset, the calibration register can be adjusted to minimize the output offset.

#### 30.3.1.6 Low Pass Filter

The low pass filter is located between the pad and the positive input. The low-pass filter is designed to couple the input signal to local VSS for high frequencies and has a 3 dB frequency of approximately 130 MHz when driven from a 50 ohm source. The filter adds a parasitic capacitance of approximately 1.2 pF towards local VSS when enabled. The filter is enabled out of reset and can be disabled by setting OPAxLPFDIS in DACn OPAxCTRL.

#### 30.3.1.7 Disabling of Rail-to-Rail Operation

Each opamp can have the input rail-to-rail stage disabled by setting the OPAxHCMDIS bit-field in DACn\_OPACTRL. Disabling the rail-to-rail input stage improves linearity of the opamp, thus improving the Total Harmonic Distortion, THD, at the cost of reduced input signal swing.

### 30.3.2 Opamp Modes

The opamp can be configured to perform different Operational Amplifier functions by configuring the internal signal routing between the opamps. The modes available are described in the following sections.

#### 30.3.2.1 General Opamp Mode

In this mode the resistor ladder is isolated from the feedback path and input signal routing is defined by OPAxPOSSEL and OPAxNEG-SEL in DACn\_OPAxMUX. The output signal routing is defined by OUTPEN in DACn\_OPAxMUX.

Table 30.1. General Opamp Mode Configuration

OPA bit-fields	OPA Configuration
OPAx POSSEL	POSPADx
OPAx NEGSEL	OPATAP, UG, NEGPADx
OPAx RESINMUX	NEXTOUT, POSPADx, NEGPADx VSS

#### 30.3.2.2 Voltage Follower Unity Gain

In this mode the unity gain feedback path is selected for the negative input by setting the OPAxNEGSEL bit-field to UG in the DACn\_OPAxMUX register as shown in the following figure. The positive input is selected by the OPAxPOSSEL bit-field, and the output is configured by the OUTPEN bit-field, both in the DACn\_OPAxMUX register.

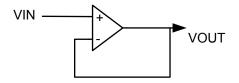

Figure 30.4. Voltage Follower Unity Gain Overview

Table 30.2. Voltage Follower Unity Gain Configuration

OPA bit-fields	OPA Configuration
OPAx POSSEL	OPATAP, NEXTOUT, POSPADx
OPAx NEGSEL	UG
OPAx RESINMUX	DISABLE

#### 30.3.2.3 Inverting Input PGA

The following figure shows the inverting input PGA configuration. In this mode the negative input is connected to the resistor ladder by setting the OPAxNEGSEL bit-field to OPATAP in the DACn\_OPAxMUX register. This setting provides a programmable gain on the negative input, which can be set by choosing the wanted gain value in the RESSEL bit-field in DACn\_OPAxMUX. Signal ground for the positive input can be generated off-chip through the pad by setting OPAxPOSSEL bitfield to PAD in DACn\_OPAxMUX. In addition the output is configured by the OUTPEN bit-field, located in DACn\_OPAxMUX.

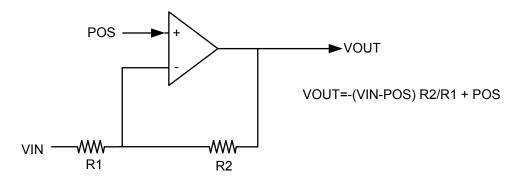

Figure 30.5. Inverting Input PGA Overview

Table 30.3. Inverting Input PGA Configuration

OPA bit-fields	OPA Configuration
OPAx POSSEL	POSPADx
OPAx NEGSEL	ОРАТАР
OPAx RESINMUX	NEXTOUT, NEGPADx, POSPADx

#### 30.3.2.4 Non-Inverting PGA

The following figure shows the non-inverting input configuration. In this mode the negative input is connected to the resistor ladder by setting the OPAxNEGSEL bit-field to OPATAP in DACn\_OPAxMUX. This setting provides a programmable gain on the negative input, which can be set by choosing the wanted gain value in the RESSEL bit-field in DACn\_OPAxMUX. In addition the OPAxRESINMUX bit-field must be set to VSS or NEGPAD in DACn\_OPAxMUX. The positive input is selected by the OPAxPOSSEL bit-field, and the output is configured by the OUTPEN bit-field, both located in DACn\_OPAxMUX.

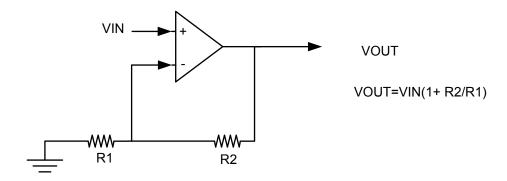

Figure 30.6. Non-Inverting PGA Overview

Table 30.4. Non-Inverting PGA Configuration

OPA bit-fields	OPA Configuration

### 30.3.2.5 Cascaded Inverting PGA

This mode enables the opamp signals to be internally configured to cascade two or three opamps in inverting mode as shown in the following figure. In both cases the positive input will be configured to signal ground by setting OPAXPOSSEL bit-field to PAD in DACn\_OPAx\_MUX. When cascaded, the negative input is connected to the resistor ladder by setting the OPAXNEGSEL bit-field to OPATAP in DACn\_OPAXMUX. The input to the resistor ladder can be configured in the OPAXRESINMUX bit-field in DAC\_nOPAXMUX. The output from OPA0 can be connected to OPA1 to create the second stage by setting the NEXTOUT bit-field in DACn\_OPAXMUX. To complete the stage, OPA1RESINMUX field must be set to OPA0INP. Similarly, the last stage can be created by setting the NEXTOUT bit-field in DACn\_OPA1MUX and OPA2RESINMUX bit-field to OPA1INP in DACn\_OPA2MUX.

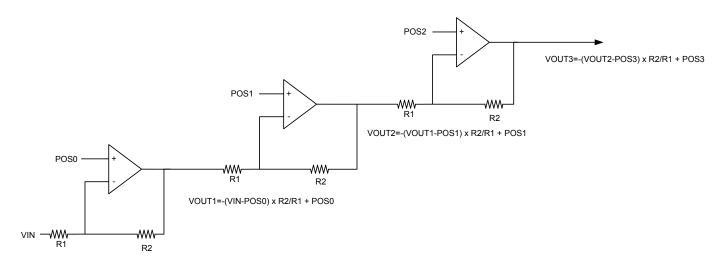

Figure 30.7. Cascaded Inverting PGA Overview

Table 30.5. Cascaded Inverting PGA Configuration

OPA	OPA bit-fields	OPA Configuration

OPA1	RESINMUX	OPA0INP
OPA1	NEXTOUT	1
OPA2	POSSEL	POSPAD2
OPA2	NEGSEL	OPATAP
OPA2	RESINMUX	OPA1INP

#### 30.3.2.6 Cascaded Non-Inverting PGA

This mode enables the opamp signals to be internally configured to cascade two or three opamps in noninverting mode as shown in the following figure. In both cases the negative input for all opamps will be connected to the resistor ladder by setting the OPAXNEGSEL bit-field to OPATAP. In addition the resistor ladder input must be set to VSS or NEGPADx in the OPAXRESINMUX in DACn\_OPAXMUX. When cascaded, the positive input on OPA0 is configured by the OPA0POSSEL bit-field. The output from OPA0 can be connected to OPA1 to create the second stage by setting NEXTOUT in DACn\_OPA0MUX. To complete the stage, the OPA1POSSEL bit-field must be set to OPA0INP in DACn\_OPA1MUX. Similarly, the last stage can be created by setting NEXTOUT in DACn\_OPA1MUX and OPA2POSSEL bit-field to OPA1INP in DACn\_OPA2MUX.

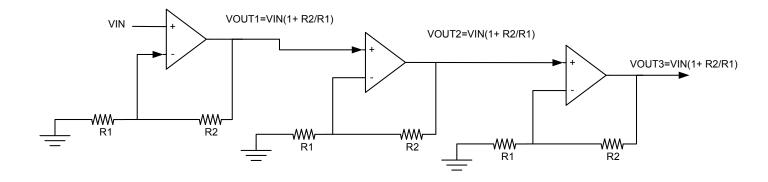

Figure 30.8. Cascaded Non-Inverting PGA Overview

Table 30.6. Cascaded Non-Inverting PGA Configuration

OPA	OPA bit-fields	OPA Configuration

OPA2	POSSEL	OPA1INP
OPA2	NEGSEL	OPATAP
OPA2	RESINMUX	VSS, NEGPAD2

### 30.3.2.7 Two Opamp Differential Amplifier

This mode enables OPA0 and OPA1 or OPA1 and OPA2 to be internally configured to form a two opamp differential amplifier as shown in the following figure. When using OPA0 and OPA1, the positive input of OPA0 can be connected to any input by configuring the OPA0POSSEL bit-field in DACn\_OPA0MUX. The OPA0 feedback path must be configured to unity gain by setting the OPA0NEGSEL bit-field to UG in DACn\_OPA0MUX. In addition, the OPA0RESINMUX bit-field must be set to DISABLED. The OPA0OUT must be connected to OPA1 by setting NEXTOUT in DACn\_OPA0MUX, and OPA1RESINMUX to OPA0INP. The positive input on OPA1 can be set by configuring OPA1POSSEL. The OPA1 output can be configured by configuring the OUTPEN and OUTMODE bit-field.

When using OPA1 and OPA2, the positive input of OPA1 can be connected to any input by configuring the OPA1POSSEL bit-field in DACn\_OPA1MUX. The OPA1 feedback path must be configured to unity gain by setting the OPA1NEGSEL bit-field to UG in DACn\_OPA1MUX. In addition, the OPA1RESINMUX bit-field must be set to DISABLED. The OPA1OUT must be connected to OPA2 by setting NEXTOUT in DACn\_OPA1MUX, and OPA2RESINMUX to OPA1INP. The positive input on OPA2 can be set by configuring OPA2POSSEL. The OPA2 output can be configured by configuring the OUTPEN and OUTMODE bit-field.

Note: When making a differential connection with the ADC, only OPA1 and OPA2 can be used

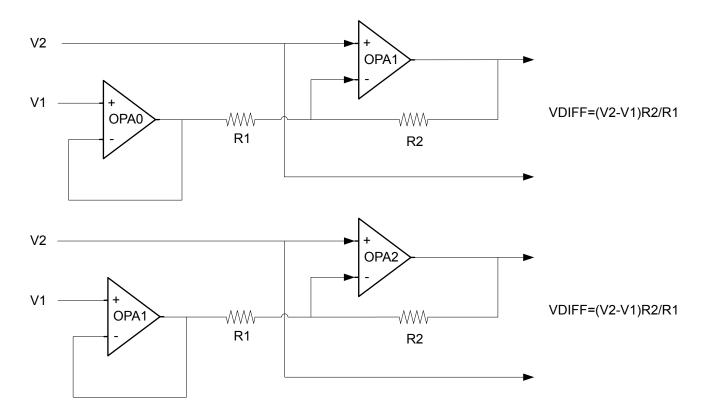

Figure 30.9. Two Opamp Differential Amplifier Overview

#### 30.3.2.8 Three Opamp Differential Amplifier

This mode enables the three opamps to be internally configured to form a three opamp differential amplifier as shown in the following figure. Both OPA0 and OPA1 can be configured in the same unity gain mode. For both OPA0/OPA1 the positive input can be connected to any input by configuring the OPA0POSSEL/OPA1POSSEL bit-field. The OPA0/OPA1 feedback path must be configured to unity gain by setting the OPA0NEGSEL/OPA1NEGSEL bit-field to UG. In addition the OPA0RESINMUX/ OPA1RESINMUX bit-fields must be set to DISABLED. The OPA1 output must be connected to OPA2 by setting the NEXTOUT bit-field in DACn\_OPA1MUX and OPA2RESINMUX to OPA1INP in DACn\_OPA2MUX. In addition the OPA2POSSEL must be set to 0PATAP. The OPA2 output can be configured by configuring the OUTPEN and OUTMODE bit-field.

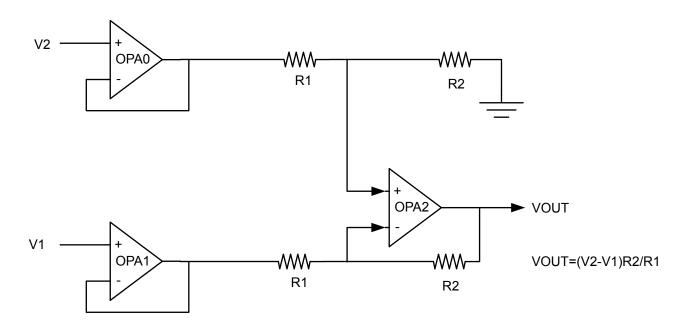

Figure 30.10. Three Opamp Differential Amplifier Overview

The gain values for the Three Opamp Differential Amplifier is determined by the combination of the gain settings of OPA0 and OPA2. The 3 different gain values available, 1/3, 1 and 3, can be programmed as shown in the table below.

Table 30.9. Three Opamp Differential Amplifier Gain Programming

Gain	OPA0 RESSEL	OPA2 RESSEL
1/3	4	0
1	1	1
3	0	4

Table 30.10. Three Opamp Differential Amplifier Configuration

OPA	OPA bit-fields	OPA Configuration

OPA2	POSSEL	ОРАТАР
OPA2	NEGSEL	ОРАТАР
OPA2	RESINMUX	OPA1INP

#### 30.3.2.9 Dual Buffer ADC Driver

It is possible to use OPA0 and OPA1 to form a Dual Buffer ADC driver as shown in the following figure. Both opamps used can be configured in the same way. The positive input is configured by setting the 0PAxPOSSEL to PAD and the negative input can be connected to the resistor ladder by setting OPATAP in DACn\_OPAxMUX. The output from the opamps can be configured to connect to the ADC by setting OUTMODE to ALT or ALL in DACn\_OPAxMUX.

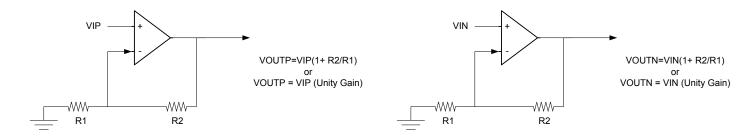

Figure 30.11. Dual Buffer ADC Driver Overview

Table 30.11. Dual Buffer ADC Driver Configuration

OPA	OPA bit-fields	OPA Configuration
OPA0	POSSEL	POSPAD0
OPA0	NEGSEL	ОРАТАР
OPA0	RESINMUX	VSS
OPA1	POSSEL	POSPAD1
OPA1	NEGSEL	ОРАТАР
OPA1	RESINMUX	VSS

### 30.3.3 Opamp DAC Combination

Since two of the opamps are part of the DAC it is not possible to use both DAC channels and all three opamps at the same time. If both DAC channels are used, only OPA2 is available out of the 3 opamps. However, it is possible to use one of the DAC channels in combination with OPA0/OPA1. OPA1 is available when DAC channel 0 is in use and OPA0 is available when DAC channel 1 is used. When using the opamp DAC combination, the DAC CONVMODE can only be configured to either CONTINUOUS or SAMPLEHOLD mode. The CONVMODE bitfield can be configured in DACn\_CTRL register. In the opamp/DAC combination, the DAC channel enabled is configured through the DAC registers while the opamp is controlled through the opamp registers.

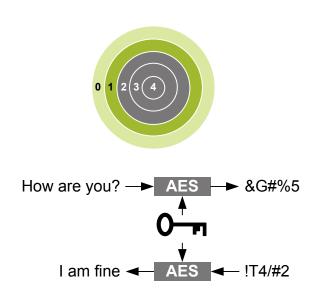

#### 30.4 Register Description

The register description of the opamp can be found in 29.5 Register Description in the DAC chapter.

#### 30.5 Register Map

The register map of the opamp can be found in 29.5 Register Description in the DAC chapter.

### 31. AES - Advanced Encryption Standard Accelerator

#### **Quick Facts**

#### What?

A fast and energy efficient hardware accelerator for AES-128 and AES-256 encryption and decryption.

#### Why?

Efficient encryption/decryption with little or no CPU intervention helps to meet the speed and energy demands of the application.

#### How?

High AES throughput allows the EFM32WG to spend more time in lower energy modes. In addition, specialized data access functions allow autonomous DMA/AES operation in both EM0 and EM1.

#### 31.1 Introduction

The Advanced Encryption Standard (FIPS-197) is a symmetric block cipher operating on 128-bit blocks of data and 128-, 192- or 256-bit keys.

The AES accelerator performs AES encryption and decryption with 128-bit or 256-bit keys. Encrypting or decrypting one 128-bit data block takes 54 HFCORECLK cycles with 128-bit keys and 75 HFCORECLK cycles with 256-bit keys. The AES module is an AHB slave which enables efficient access to the data and key registers. All write accesses to the AES module must be 32-bit operations, i.e. 8- or 16-bit operations are not supported.

#### 31.2 Features

- · AES hardware encryption/decryption
  - 128-bit key (54 HFCORECLK cycles)
  - 256-bit key (75 HFCORECLK cycles)
- · Efficient CPU/DMA support
- · Interrupt on finished encryption/decryption
- · DMA request on finished encryption/decryption
- · Key buffer in AES128 mode
- · Optional XOR on Data write
- · Configurable byte ordering

#### 31.3 Functional Description

Some data and a key must be loaded into the KEY and DATA registers before an encryption or decryption can take place. The input data before encryption is called the PlainText and output from the encryption is called CipherText. For encryption, the key is called PlainKey. After one encryption, the resulting key in the KEY registers is the CipherKey. This key must be loaded into the KEY registers before every decryption. After one decryption, the resulting key will be the PlainKey. The resulting PlainKey/CipherKey is only dependent on the value in the KEY registers before encryption/decryption. The resulting keys and data are shown in the following figure.

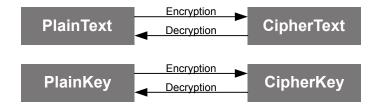

Figure 31.1. AES Key and Data Definitions

### 31.3.1 Encryption/Decryption

The AES module can be set to encrypt or decrypt by clearing/setting the DECRYPT bit in AES\_CTRL. The AES256 bit in AES\_CTRL configures the size of the key used for encryption/decryption. The AES\_CTRL register should not be altered while AES is running, as this may lead to unpredictable behaviour.

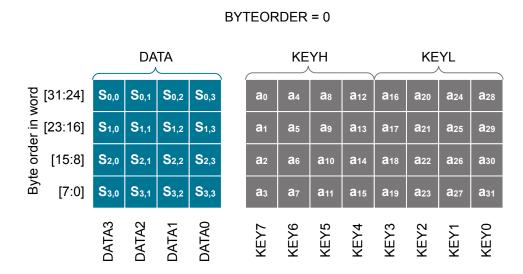

An AES encryption/decryption can be started in the following ways:

- · Writing a 1 to the START bit in AES CMD
- · Writing 4 times 32 bits to AES DATA when the DATASTART control bit is set
- · Writing 4 times 32 bits to AES XORDATA when the XORSTART control bit is set

An AES encryption/decryption can be stopped by writing a 1 to the STOP bit in AES\_CMD. The RUNNING bit in AES\_STATUS indicates that an AES encryption/decryption is ongoing.

#### 31.3.2 Data and Key Access

The AES module contains a 128-bit DATA (State) register and two 128-bit KEY registers defined as DATA3-DATA0, KEY3-KEY0 (KEYL) and KEY7-KEY4 (KEYH). In AES128 mode, the 128-bit key is read from KEYL, while both KEYH and KEYL are used in AES256 mode. The AES module has configurable byte ordering which is configured in BYTEORDER in AES\_CTRL. The following figure illustrates how data written to the AES registers is mapped to the key and state defined in the Advanced Encryption Standard (FIPS-197). The figure presents the key byte order for 256-bit keys. In 128-bit mode with BYTEORDER cleared, a<sub>16</sub> represents the first byte of the 128-bit key. When BYTEORDER is set, a<sub>0</sub> represents the first byte in the key. AES encryption/decryption takes two extra cycles when BYTEORDER is set. BYTEORDER has to be set prior to loading the data and key registers.

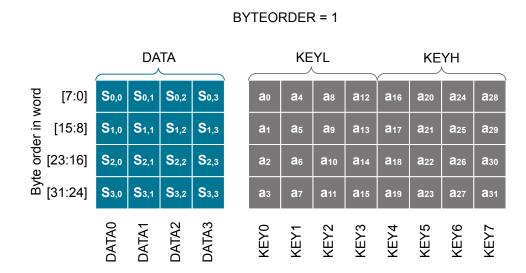

Figure 31.2. AES Data and Key Orientation as Defined in the Advanced Encryption Standard

The registers DATA3-DATA0, are not memory mapped directly, but can be written/read by accessing AES\_DATA or AES\_XORDATA. The same applies for the key registers, KEY3-KEY0 which are accessed through AES\_KEYLn (n=A, B, C or D), while KEY7-KEY4 are accessed through KEYHn (n=A, B, C or D). Writing DATA3-DATA0 is then done through 4 consecutive writes to AES\_DATA (or AES\_XORDATA), starting with the word which is to be written to DATA0. For each write, the words will be word wise barrel shifted towards the least significant word. Accessing the KEY registers are done in the same fashion through KEYLn and KEYHn. See the following figure. Note that KEYHA, KEYHB, KEYHC and KEYHD are really the same register, just mapped to four different addresses. You can then choose freely which of these addresses you want to use to update the KEY7-KEY4 registers. The same principle applies

to the KEYLn registers. Mapping the same registers to multiple addresses like this, allows the DMA controller to write a full 256-bit key in one sweep, when incrementing the address between each word write.

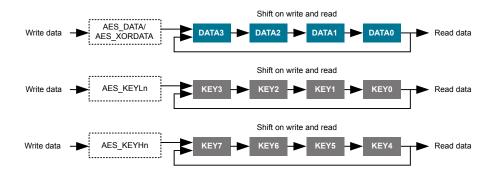

Figure 31.3. AES Data and Key Register Operation

#### 31.3.2.1 Key Buffer

When encrypting multiple blocks of data in a row, the PlainKey must be written to the key register between each encryption, since the contents of the key registers will be turned into the CipherKey during the encryption. The opposite applies when decrypting, where you have to re-supply the CipherKey between each block. However, in AES128 mode, KEY4-KEY7 can be used as a buffer register, to hold an extra copy of the KEY3-KEY0 registers. When KEYBUFEN is set in AES\_CTRL, the contents of KEY7-KEY4 are copied to KEY3-KEY0, when an encryption/decryption is started. This eliminates the need for re-loading the KEY for every encrypted/decrypted block when running in AES128 mode.

#### 31.3.2.2 Data Write XOR

The AES module contains an array of XOR gates connected to the DATA registers, which can be used during a data write to XOR the existing contents of the registers with the new data written. To use the XOR function, the data must be written to AES\_XORDATA location.

Reading data from AES\_XORDATA is equivalent to reading data from AES\_DATA.

#### 31.3.2.3 Start on Data Write

The AES module can be configured to start an encryption/decryption when the new data has been written to AES\_DATA and/or AES\_XORDATA. A 2-bit counter is incremented each time the AES\_DATA or AES\_XORDATA registers are written. This counter indicates which data word is written. If DATASTART/ XORSTART in AES\_CTRL is set, an encryption will start each time the counter overflows (DATA3 is written). Writing to the AES\_CTRL register will reset the counter to 0.

#### 31.3.3 Interrupt Request

The DONE interrupt flag is set when an encryption/ decryption has finished.

#### 31.3.4 DMA Request

The AES module has 4 DMA requests which are all set on a finished encryption/decryption and cleared on the following conditions:

- · DATAWR: Cleared on a AES DATA write or AES CTRL write
- · XORDATAWR: Cleared on a AES\_XORDATA write or AES\_CTRL write
- · DATARD: Cleared on a AES DATA read or AES CTRL write
- · KEYWR: Cleared on a AES\_KEYHn write or AES\_CTRL write

### 31.3.5 Block Chaining Example

The example below illustrates how the AES module could be configured to perform Cipher Block Chaining with 128-bit keys.

- 1. Configure module to encryption, key buffer enabled and XORSTART in AES\_CTRL.
- 2. Write 128-bit initialization vector to AES\_DATA, starting with least significant word.
- 3. Write PlainKey to AES KEYHn, starting with least significant word.
- 4. Write PlainText to AES\_XORDATA, starting with least significant word. Encryption will be started when the DATA3 is written. KEYH (PlainKey) will be copied to KEYL before encryption starts.
- 5. When encryption finished, read CipherText from AES\_DATA, starting with least significant word.
- 6. Loop to step 4, if new PlainText is available.

#### 31.4 Register Map

### 32. GPIO - General Purpose Input/Output

#### **Quick Facts**

#### What?

The GPIO (General Purpose Input/Output) is used for pin configuration and direct pin manipulation and sensing as well as routing for peripheral pin connections.

#### Why?

Easy to use and highly configurable input/ output pins are important to fit many communication protocols as well as minimizing software control overhead. Flexible routing of peripheral functions helps to ease PCB layout.

#### How?

Each pin on the device can be individually configured as either an input or an output with several different drive modes. Also, individual bit manipulation registers minimizes control overhead. Peripheral connections to pins can be routed to several different locations, thus solving congestion issues that may arise with multiple functions on the same pin. Fully asynchronous interrupts can also be generated from any pin.

#### 32.1 Introduction

In the EFM32WG devices the General Purpose Input/Output (GPIO) pins are organized into ports with up to 16 pins each. These pins can individually be configured as either an output or input. More advanced configurations like open-drain, filtering and drive strength can also be configured individually for the pins. The GPIO pins can also be overridden by peripheral pin connections, like Timer PWM outputs or USART communication, which can be routed to several locations on the device. The GPIO supports up to 16 asynchronous external pin interrupts, which enables interrupts from any pin on the device. Also, the input value of a pin can be routed through the Peripheral Reflex System to other peripherals.

#### 32.2 Features

- · Individual configuration for each pin
  - · Tristate (reset state)
  - Push-pull
  - · Open-drain
  - · Pull-up resistor
  - · Pull-down resistor
  - · Four drive strength modes
    - HIGH
    - STANDARD
    - LOW
    - LOWEST
- · EM4 IO pin retention. This includes
  - · Output enable
  - · Output value
  - · Pull enable
  - · Pull direction
- · EM4 wake-up on selected GPIO pins
- · Glitch suppression input filter.
- · Analog connection to e.g. ADC or LCD.
- · Alternate functions (e.g. peripheral outputs and inputs)
  - · Routed to several locations on the device
  - · Pin connections can be enabled individually
  - · Output data can be overridden by peripheral
  - · Output enable can be overridden by peripheral
- · Toggle, set and clear registers for output data
- · Dedicated data input register (read-only)
- · Interrupts
  - · 2 interrupt lines from up to 16 pending sources
    - · All GPIO pins are selectable
  - · Separate enable, status, set and clear registers
  - · Asynchronous sensing
  - · Rising, falling or both edges
  - · Wake up from EM0-EM3
- · Peripheral Reflex System producer
  - · All GPIO pins are selectable
- · Configuration lock functionality to avoid accidental changes

#### 32.3 Functional Description

An overview of the GPIO module is shown in Figure 32.1 Pin Configuration on page 971. The GPIO pins are grouped into 16- pin ports. Each individual GPIO pin is called Pxn where x indicates the port (A, B, C ...) and n indicates the pin number (0,1,....,15). Fewer than 16 bits may be available on some ports, depending on the total number of I/O pins on the package. After a reset both input and output is disabled for all pins on the device, except for debug pins. To use a pin, the port GPIO\_Px\_MODEL/GPIO\_Px\_MODEH registers must be configured for the pin to make it an input or output. These registers can also do more advanced configuration, which is covered in 32.3.1 Pin Configuration. When the port is either configured as an input or an output, the Data In Register (GPIO\_Px\_DIN) can be used to read the level of each pin in the port (bit n in the register is connected to pin n on the port). When configured as an output, the value of the Data Out Register (GPIO\_Px\_DOUT) will be driven to the pin.

The DOUT value can be changed in 4 different ways

- · Writing to the GPIO Px DOUT register.
- · Writing a 1 to a bit in the GPIO Px DOUTSET register sets the corresponding DOUT bit
- · Writing a 1 to a bit in the GPIO Px DOUTCLR register clears the corresponding DOUT bit
- Writing a 1 to a bit in the GPIO\_Px\_DOUTTGL register toggles the corresponding DOUT bit

Reading the GPIO\_Px\_DOUT register will return its contents. Reading the GPIO\_Px\_DOUTSET, GPIO\_Px\_CLR or GPIO\_Px\_TGL will return 0.

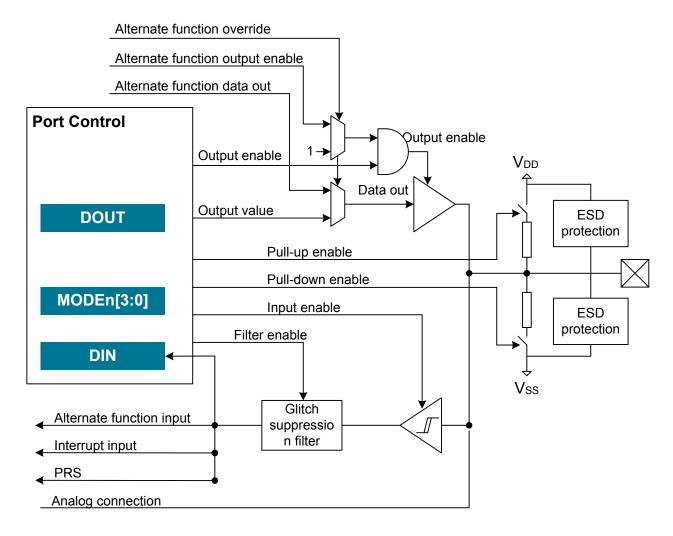

Figure 32.1. Pin Configuration

**Note:** There is no ESD diode to Vdd because if using LCD voltage boost the pin voltage will be higher than Vdd. Nevertheless there is an ESD protection block against over voltage.

#### 32.3.1 Pin Configuration

In addition to setting the pins as either outputs or inputs, the GPIO\_Px\_MODEL and GPIO\_Px\_MODEH registers can be used for more advanced configurations. GPIO\_Px\_MODEL contains 8 bit fields named MODEn (n=0,1,..7) which control pins 0-7, while GPIO\_Px\_MODEH contains 8 bit fields named MODEn (n=8,9,..15) which control pins 8-15. In some modes GPIO\_Px\_DOUT is also used for extra configurations like pull-up/down and glitch suppression filter enable. The following table shows the available configurations.

MODEn	Input	Output	DOUT	Pulldown	Pullup	Alt. strength	Input Filter	Description
0b0000	Disabled	Disabled	0					Input disabled
			1		On			Input disabled with pull-up
0b0001	Enabled		0					Input enabled
			1				On	Input enabled with filter
0b0010			0	On				Input enabled with pull-down
			1		On			Input enabled with pull-up
0b0011			0	On			On	Input enabled with pull-down and filter
			1		On		On	Input enabled with pull-up and filter
0b0100		Push-pull	х					Push-pull
0b0101			х			On		Push-pull with alt. drive strength
0b0110		Open Source (Wired-	х					Open-source
0b0111		OR)	х	On				Open-source with pull-down
0b1000		Open Drain (Wired-						Open-drain
0b1001		AND)	х				On	Open-drain with filter
0b1010			х		On			Open-drain with pull-up
0b1011			х		On		On	Open-drain with pull-up and filter
0b1100			х			On		Open-drain with alt. drive strength
0b1101			x			On	On	Open-drain with alt. drive strength and filter
0b1110			x		On	On		Open-drain with alt. drive strength and pull-up
0b1111			x		On	On	On	Open-drain with alt. drive strength, pull-up and filter

MODEn determines which mode the pin is in at a given time. Setting MODEn to 0b0000 disables the pin, reducing power consumption to a minimum. When the output driver is disabled, the pin can be used as a connection for an analog module (e.g. ADC, LCD...). Input is enabled by setting MODEn to any value other than 0b0000. The pull-up, pull-down and filter function can optionally be applied to the input, see Figure 32.2 Tristated Output with Optional Pull-up or Pull-down on page 973.

The internal pull-up resistance, RPU, and pull-down resistance, RPD, are defined in the device datasheet. When the filter is enabled it suppresses glitches with pulse widths as defined by the parameter tIOGLITCH in the device datasheet.

Figure 32.2. Tristated Output with Optional Pull-up or Pull-down

When MODEn=0b0100 or MODEn=0b0101, the pin operates in push-pull mode. In this mode, the pin is driven either high or low, dependent on the value of GPIO\_Px\_DOUT. The push-pull configuration is shown in Figure 32.3 Push-Pull Configuration on page 973.

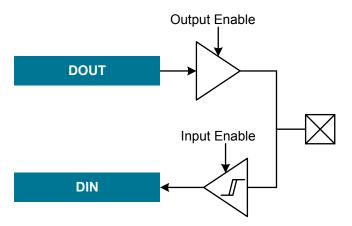

Figure 32.3. Push-Pull Configuration

When MODEn is 0110 or 0111, the pin operates in open-source mode, the latter with a pull-down resistor. When driving a high value in open-source mode, the pull-down is disconnected to save power.

For the remaining MODEn values, i.e. MODEn >= 1000, the pin operates in open-drain mode as shown in Figure 32.4 Open-Drain on page 974. In open-drain mode, the pin can have an input filter, a pull-up, different driver strengths or any combination of these. When driving a low value in open-drain mode, the pull-up is disconnected to save power.

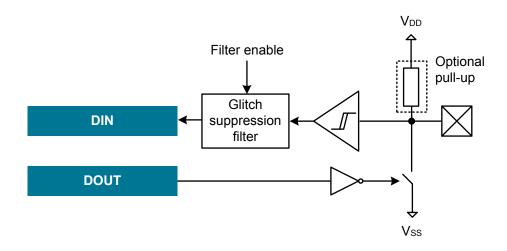

Figure 32.4. Open-Drain

When MODEn=0b0101 or 0b11xx, the output driver uses the drive strength specified in DRIVEMODE in GPIO\_Px\_CTRL. In all other output modes, the drive strength is set to STANDARD.

### 32.3.1.1 Configuration Lock

GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_CTRL, GPIO\_Px\_PINLOCKN, GPIO\_EXTIPSELL, GPIO\_EXTIPSELH, GPIO\_INSENSE and GPIO\_ROUTE can be locked by writing any other value than 0xA534 to GPIO\_LOCK. Writing the value 0xA534 to the GPIOx LOCK register unlocks the configuration registers.

In addition to configuration lock, GPIO\_Px\_MODEL, GPIO\_Px\_MODEH, GPIO\_Px\_DOUT, GPIO\_Px\_DOUTSET, GPIO\_Px\_DOUTCLR, and GPIO\_Px\_DOUTTGL can be locked individually for each pin by clearing the corresponding bit in GPIO\_Px\_PINLOCKN. Bits in the GPIO\_Px\_PINLOCKN register can only be cleared, they are set high again after reset.

### 32.3.2 EM4 Wake-Up

It is possible to wake-up from EM4 through reset triggered from any of up to 6 selectable GPIO pins. For the wake-up logic to work correctly, EM4 retention needs to be enabled before entering EM4, as described in 32.3.3 EM4 Retention The wake-up request can be triggered through the pins by enabling the corresponding bit in the GPIO\_EM4WUEN register. When EM4 wake-up is enabled for the pin, the input filter is enabled during EM4. This is done to avoid false wake-up caused by glitches. In addition, the polarity of the EM4 wake-up request can be selected using the GPIO\_EM4WUPOL register.

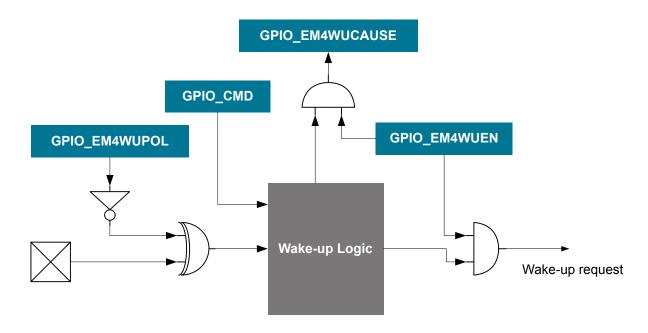

Figure 32.5. EM4 Wake-Up Logic

The pins used for EM4 wake-up must be configured as inputs using the GPIO\_Px\_MODEL/ GPIO\_Px\_MODEH register. Before going down to EM4, it is important to clear the wake-up logic by setting the EM4WUCLR bitfield in the GPIO\_CMD register, which clears the complete wake-up logic, including the GPIO\_EM4WUCAUSE register. When the chip comes out of reset, it is possible to determine what caused the reset by reading the RMU\_RSTCAUSE register. If an EM4 wake-up reset occurred, the EM4RST (indicating the chip was in EM4) and the EM4WU (indicating the EM4 wake-up reset) bits should be set. It is possible to determine which pin caused the reset by reading the GPIO\_EM4WUCAUSE register. The mapping between pins and the bits in the GPIO\_EM4WUEN, GPIO\_EM4WUPOL, and GPIO\_EM4WUCAUSE registers are described in Table 32.1 EM4 WU Register Bits to Pin Mapping on page 975

 bit 1
 A6

 bit 2
 C9

 bit 3
 F1

 bit 4
 F2

 bit 5
 E13

Table 32.1. EM4 WU Register Bits to Pin Mapping

#### 32.3.3 EM4 Retention

It is possible to enable retention of output enable, output value, pull enable and pull direction when in EM4. EM4 retention also makes it possible to wake up from EM4 on pin reset as described in 32.3.2 EM4 Wake-Up EM4 retention can be enabled by setting the EM4RET field in GPIO\_CTRL register before going down in EM4.

#### 32.3.4 Alternate Functions

Alternate functions are connections to pins from Timers, USARTs etc. These modules contain route registers, where the pin connections are enabled. In addition, these registers contain a location bit field, which configures which pins the outputs of that module will be connected to if they are enabled. If an alternate signal output is enabled for a pin and output is enabled for the pin, the alternate function's output data and output enable signals override the data output and output enable signals from the GPIO. However, the pin configuration stays as set in GPIO\_Px\_MODEL, GPIO\_Px\_MODEH and GPIO\_Px\_DOUT registers. I.e. the pin configuration must be set to output enable in GPIO for a peripheral to be able to use the pin as an output.

It is possible, but not recommended to select two or more peripherals as output on the same pin. These signals will then be OR'ed together. However, TIMER CCx and CDTIx outputs, which are routed as alternate functions, have priority, and will never be OR'ed with other alternate functions. The reader is referred to the pin map section of the device datasheet for more information on the possible locations of each alternate function and any priority settings.

#### 32.3.4.1 Serial Wire Debug Port Connection

The SW Debug Port is routed as an alternate function and the SWDIO and SWCLK pin connections are enabled by default with internal pull-up and pull-down resistors, respectively. It is possible to disable these pin connections (and disable the pull resistors) by setting the SWDIOPEN and SWCLKPEN bits in GPIO\_ROUTE to 0.

When the debug pins are disabled, the device can no longer be accessed by a debugger. A reset will set the debug pins back to their default state as enabled. If you do disable the debug pins, make sure you have at least a 3 second timeout at the start of your program code before you disable the debug pins. This way the debugger will have time to halt the device after a reset before the pins are disabled.

The Serial Wire Viewer Output pin (SWO) can be enabled by setting the SWOPEN bit in GPIO\_ROUTE. This bit can also be routed to alternate locations by configuring the LOCATION bitfield in GPIO\_ROUTE.

#### 32.3.4.2 ETM Trace Ports

There are five trace pins available on the device. One trace clock which can be enabled by setting the TCLKPEN bitfield in GPIO\_ROUTE. The four data pins can be enabled individually by setting TD0PEN, TD1PEN, TD2PEN, and TD3PEN respectively in GPIO\_ROUTE. It is possible to choose which pins the trace data will be exported to. The lowest trace bit will be routed to the first enabled trace pin. For example, if the ETM data port size is 2 bits and TD0 and TD3 are enabled, will make bit 0 be routed to TD0 while bit 1 will be routed to TD3.

Both the TCLK and all the TD pins can also be routed to alternate locations by configuring the ETMLOCATION bitifeld in GPIO ROUTE.

#### 32.3.4.3 Analog Connections

When using the GPIO pin for analog functionality, it is recommended to disable the digital output and set the MODEn in GPIO\_Px\_MODEL/GPIO\_Px\_MODEH equal to 0b0000 to disable the input sense and pull resistors.

#### 32.3.5 Interrupt Generation

The GPIO can generate an interrupt from the input of any GPIO pin on a device. The interrupts have asynchronous sense capability, enabling wake-up from energy modes as low as EM3, see Figure 32.6 Pin n Interrupt Generation on page 977.

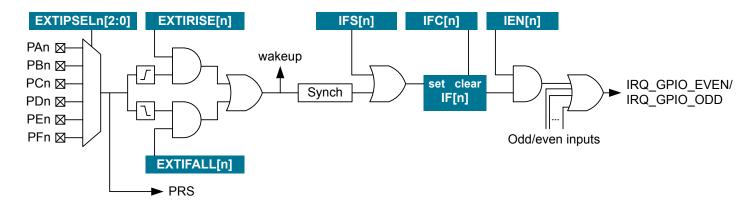

Figure 32.6. Pin n Interrupt Generation

All pins with the same pin number (n) are grouped together to trigger one interrupt flag (EXT[n] in GPIO\_IF). The EXTIPSELn[2:0] bits in GPIO\_EXTIPSELL or GPIO\_EXTIPSELH select which port will trigger the interrupt flag. The GPIO\_EXTIRISE[n] and GPIO\_EXTIFALL[n] registers enables sensing of rising and falling edges. By setting the EXT[n] bit in GPIO\_IEN, a high interrupt flag n, will trigger one of two interrupt lines. The even interrupt line is triggered by any enabled even numbered interrupt flag, while the odd is triggered by odd flags. The interrupt flags can be set and cleared by software by writing the GPIO\_IFS and GPIO\_IFC registers, see the following example. Since the external interrupts are asynchronous, they are sensitive to noise. To increase noise tolerance, the MODEL and MODEH fields in the GPIO\_Px\_MODEL and GPIO\_Px\_MODEH registers, respectively, should be set to include filtering for pins that have external interrupts enabled.

#### **GPIO Interrupt Example**

Setting EXTIPSEL3 in GPIO\_EXTIPSELL to 2 (Port C) and setting the GPIO\_EXTIRISE[3] bit, the interrupt flag EXT[3] in GPIO\_IF will be triggered by a rising edge on pin 3 on PORT C. If EXT[3] in GPIO\_IEN is set as well, a interrupt request will be sent on IRQ\_GPIO\_ODD.

#### 32.3.6 Output to PRS

All pins with the same pin number (n) are grouped together to form one PRS producer output, giving a total of 16 outputs to the PRS. The port on which the output n should be taken is selected by the EXTIPSELn[3:0] bits in the GPIO\_EXTIPSELL or the GPIO\_EXTIPSELH registers.

#### 32.3.7 Synchronization

To avoid metastability in synchronous logic connected to the pins, all inputs are synchronized with double flip-flops. The flip-flops for the input data run on the HFCORECLK. Consequently, when a pin changes state, the change will have propagated to GPIO\_Px\_DIN after 2 positive HFCORECLK edges, or maximum 2 HFCORECLK cycles.

Synchronization (also running on the HFCORECLK) is also added for interrupt input. The input to the PRS generation is also synchronized, but these flip-flops run on the HFPERCLK. To save power when the external interrupts or PRS generation is not used, the synchronization flip-flops for these can be turned off by clearing the INTSENSE or PRSSENSE, respectively, in GPIO\_INSENSE register.

**Note:** To use the GPIO, the GPIO clock must first be enabled in CMU\_HFPERCLKEN0. Setting this bit enables the HFCORECLK and the HFPERCLK for the GPIO. HFCORECLK is used for updating registers, while HFPERCLK is only used to synchronize PRS and interrupts. The PRS and interrupt synchronization can also be disabled through GPIO INSENSE, if these are not used.

## 32.4 Register Map

The offset register address is relative to the registers base address.

### 33. LCD - Liquid Crystal Display Driver

#### **Quick Facts**

#### What?

The LCD driver can drive up to 8x36 segmented LCD directly. The LCD driver consumes less than 900 nA in EM2. The animation feature makes it possible to have active animations without CPU intervention.

#### Why?

Segmented LCD displays are common way to display information. The extreme low-power LCD driver enables a lot of applications to utilize an LCD display even in energy critical systems.

#### How?

The low frequency clock signal, low-power waveform, animation and blink capabilities enable the LCD driver to run autonomously in EM2 for long periods. Adding the flexible frame rate setting, contrast control, and different multiplexing modes make the EFM32WG the optimal choice for battery-driven systems with LCD panels.

#### 33.1 Introduction

The LCD driver is capable of driving a segmented LCD display combination of: 1x40, 2x40, 3x40, 4x40, 6x38 or 8x36 segments. A voltage boost function enables it to provide the LCD display with higher voltage than the supply voltage for the device. In addition, an animation feature can run custom animations on the LCD display without any CPU intervention. The LCD driver can also remain active even in Energy Mode 2 and provides a Frame Counter interrupt that can wake-up the device on a regular basis for updating data.

#### 33.2 Features

- · Up to 8x36 segments
- Configurable multiplexing (1, 2, 3, 4, 6, 8)
- · LCD supports the following COM/SEG combinations
  - 1x40, 2x40, 3x40, 4x40, 6x38, 8x36
- Configurable bias/voltage levels settings
- · Configurable clock source prescaler
- · Configurable Frame rate
- · Segment lines can be enabled or disabled individually
- Blink capabilities
- · Integrated animation functionality
  - · Available on SEG0-SEG7 or SEG8-SEG15
- · Voltage boost capabilities
- · Possible to run on external power
- · Programmable contrast
- Frame Counter
- · LCD frame interrupt
- · Direct segment control

#### 33.3 Functional Description

An overview of the LCD module is shown in the following figure. In its simplest form, an LCD driver would apply a voltage above a certain threshold voltage in order to darken a segment and a voltage below threshold to make a segment clear. However, the LCD display segment will degrade if the applied voltage has a DC-component. To avoid this, the applied waveforms are arranged such that the differential voltage seen by each segment has an average value of zero, and such that the RMS voltage (or differential sum of the two waveforms for fast response LCDs) is below the segment threshold voltage if the segment shall be transparent, and above the segment threshold voltage when the segment shall be dark.

The waveforms are multiplexed between eight (1-8) different common lines and 20-36 segment lines to support up to 288 different LCD segments. The common lines and segment lines can be enabled or disabled individually to prevent the LCD driver from occupying more I/O resources than required.

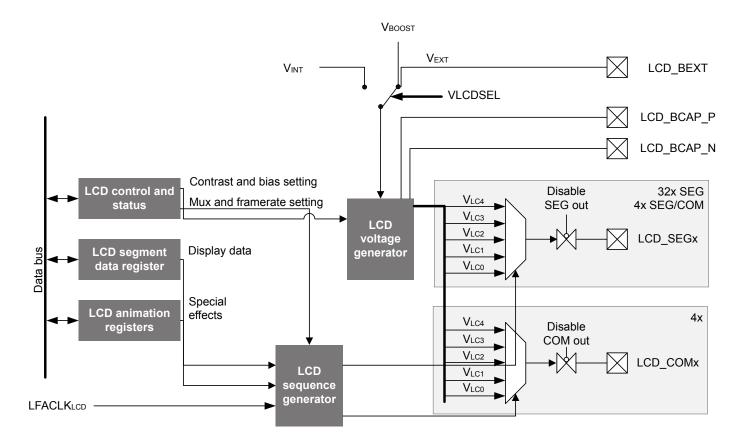

Figure 33.1. LCD Block Diagram

For simplicity, only one segment pin and one common terminal is shown in the figure.

#### 33.3.1 LCD Driver Enable

Setting the EN bit in LCD\_CTRL enables the LCD driver. The MUX bit-field in LCD\_DISPCTRL determines which COM lines are driven by the LCD driver. By default, LCD\_COM0 is driven whenever the LCD driver is enabled.

The LCD\_SEGEN register determines which segment lines are enabled. Segment lines can be enabled in groups of 4 and disabled in groups of 4 or individually disabled. To enable output on segment lines 0-7 for instance, the two lowest segment groups, set the two lowest bits in LCD\_SEGEN. Each LCD segment pin can also be individually disabled by setting the pin to any other state than DISA-BLED in the GPIO pin configuration.

Each LCD segment pin can also be individually disabled by setting the pin to any other state than DISABLED in the GPIO pin configuration.

#### 33.3.2 Multiplexing, Bias, and Wave Settings

The LCD driver supports different multiplexing and bias settings, and these can be set individually in the MUX and BIAS bits in LCD DISPCTRL respectively, see the following two tables.

**Note:** If the MUX and BIAS settings in LCD\_DISPCTRL are changed while the LCD driver is enabled, the output waveform is unpredictable and may lead to a DC-component for one LCD frame.

The MUX setting determines the number of LCD COM lines that are enabled. When using octaplex or sextaplex multiplexing, the additional COM lines used (COM4-COM7) are actually located on the SEG (SEG20-SEG23) lines. When static multiplexing is selected, LCD output is enabled on LCD\_COM0, when duplex multiplexing is used, LCD\_COM0-LCD\_COM1 are used, when triplex multiplexing is selected, LCD\_COM0-LCD\_COM2 are used, when quadruplex multiplexing is selected, LCD\_COM0-LCD\_COM3 are used, when sextaplex multiplexing is selected, LCD\_COM0-LCD\_COM3 together with SEG20-SEG21 as LCD\_COM4-LCD\_COM5 are used, making 38 segments available, located in SEG0-SEG19, and SEG22-SEG39. Finally when octaplex multiplexing is selected, LCD\_COM0-LCD\_COM3 together with SEG20-SEG23 as LCD\_COM4-LCD\_COM7 are used, making the 36 segments available, located in SEG0-SEG19, and SEG24-SEG39.

See 33.3.3 Waveform Examples for waveforms for the different bias and multiplexing settings.

The waveforms generated by the LCD controller can be generated in two different versions, regular and low-power. The low power mode waveforms have a lower switching frequency than the regular waveforms, and thus consume less power. The WAVE bit in LCD\_DISPCTRL decides which waveforms to generate. An example of a low-power waveform is shown in Figure 33.2 LCD Low-power Waveform for LCD\_COM0 in Quadruples Multiplex Mode, 1/3 Bias on page 1004, and an example of a regular waveform is shown in Figure 33.3 LCD Normal Waveform for LCD\_COM0 in Quadruples Multiplex Mode, 1/3 Bias on page 1004.

**MUXE** MUX Mode Multiplexing 0 00 Static Static (segments can be multiplexed with LCD COM[0]) 01 0 Duplex Duplex (segments can be multiplexed with LCD COM[1:0]) 0 10 Triplex Triplex (segments can be multiplexed with LCD COM[2:0]) 0 11 Quadruplex Quadruplex (segments can be multiplexed with LCD COM[3:0]) 01 Sextaplex Sextaplex (segments can be multiplexed with LCD COM[3:0] and SEG[21:20]) 11 Octaplex (segments can be multiplexed with LCD COM[3:0]) and 1 Octaplex SEG[23:20]

### 33.3.3 Waveform Examples

The numbers on the illustration's y-axes in the following sections only indicate different voltage levels. All examples are shown with low-power waveforms.

### 33.3.3.1 Waveforms with Static Bias and Multiplexing

- With static bias and multiplexing, each segment line can be connected to LCD\_COM0. When the segment line has the same waveform as LCD\_COM0, the LCD panel pixel is turned off, while when the segment line has the opposite waveform, the LCD panel pixel is turned on.
- DC voltage = 0 (over one frame)
- V<sub>RMS</sub> (on) = V<sub>LCD\_OUT</sub>
- V<sub>RMS</sub> (off) = 0 (V<sub>SS</sub>)

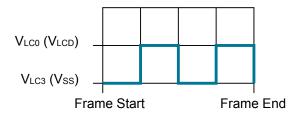

Figure 33.4. LCD Static Bias and Multiplexing - LCD\_COM0

#### 33.3.3.2 Waveforms with 1/2 Bias and Duplex Multiplexing

In this mode, each frame is divided into 4 periods. LCD\_COM[1:0] lines can be multiplexed with all segment lines. Figures show 1/2 bias and duplex multiplexing (waveforms show two frames)

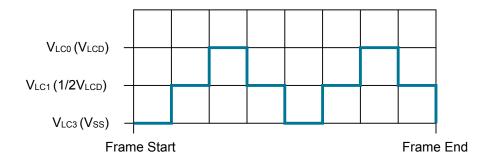

Figure 33.5. LCD 1/2 Bias and Duplex Multiplexing - LCD\_COM0

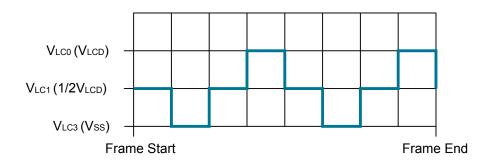

Figure 33.6. LCD 1/2 Bias and Duplex Multiplexing - LCD\_COM1

1/2 bias and duplex multiplexing - LCD\_SEG0

The LCD\_SEG0 waveform on the left is just an example to illustrate how different segment waveforms can be multiplexed with the LCD\_COM lines in order to turn on and off LCD pixels. As illustrated in the figures below, this waveform will turn ON pixels connected to LCD\_COM0, while pixels connected to LCD\_COM1 will be turned OFF.

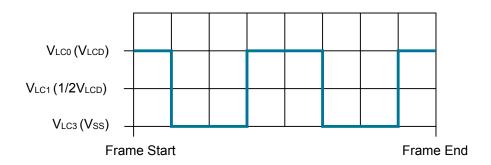

Figure 33.7. LCD 1/2 Bias and Duplex Multiplexing - LCD\_SEG0

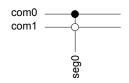

Figure 33.8. LCD 1/2 Bias and Duplex Multiplexing - LCD\_SEG0 Connection

1/2 bias and duplex multiplexing - LCD\_SEG0-LCD\_COM0

- DC voltage = 0 (over one frame)
- $V_{RMS} = 0.79 \times V_{LCD\_OUT}$
- The LCD display pixel that is connected to LCD\_SEG0 and LCD\_COM0 will be ON with this waveform.

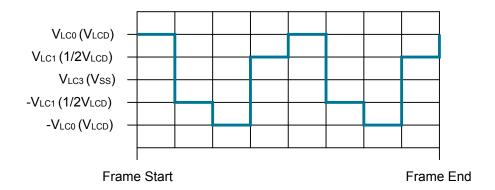

Figure 33.9. LCD 1/2 Bias and Duplex Multiplexing - LCD\_SEG0-LCD\_COM0

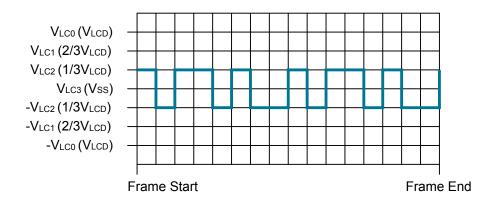

Figure 33.42. LCD 1/3 Bias and Quadruplex Multiplexing- LCD\_SEG0-LCD\_COM3

#### 33.3.4 LCD Contrast

Different LCD panels have different characteristics and also temperature may affect the characteristics of the LCD panels. To compensate for such variations, the LCD driver has a programmable contrast that adjusts the  $V_{LCD\_OUT}$ . The contrast is set by CONLEV in LCD\_DISPCTRL, and can be adjusted relative to either  $V_{DD}$  ( $V_{LCD}$ ) or Ground using CONCONF in LCD\_DISPCTRL. See the following tables.

Table 33.4. LCD Contrast

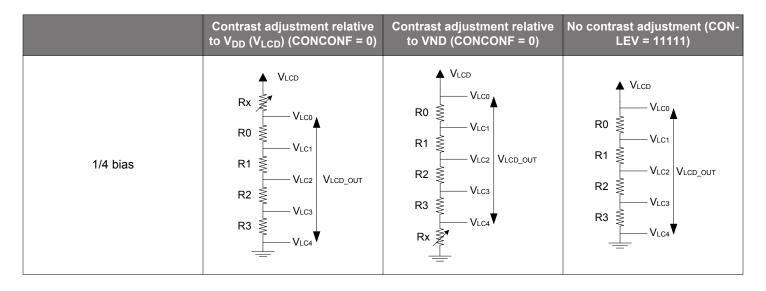

BIAS	CONLEV	Equation	Range
00	00000-11111	V <sub>LCD_OUT</sub> = V <sub>LCD</sub> x (0.61 x (1 + CONLEV/(2 <sup>5</sup> - 1)))	CONLEV = 0 => V <sub>LCD_OUT</sub> = 0.61V <sub>LCD</sub>
			CONLEV = 31 => V <sub>LCD_OUT</sub> = V <sub>LCD</sub>
01	00000-11111	V <sub>LCD_OUT</sub> = V <sub>LCD</sub> x (0.53 x (1 + CONLEV/(2 <sup>5</sup> - 1)))	CONLEV = 0 => V <sub>LCD_OUT</sub> = 0.53V <sub>LCD</sub>
			CONLEV = 31 => V <sub>LCD_OUT</sub> = V <sub>LCD</sub>
10	00000-11111	V <sub>LCD_OUT</sub> = V <sub>LCD</sub> x (0.61 x (1 + CONLEV/(2 <sup>5</sup> - 1)))	CONLEV = 0 => V <sub>LCD_OUT</sub> = 0.61V <sub>LCD</sub>
			CONLEV = 31 => V <sub>LCD_OUT</sub> = V <sub>LCD</sub>
11	00000-11111	V <sub>LCD_OUT</sub> = V <sub>LCD</sub> x (0.61 x (1 + CONLEV/(2 <sup>5</sup> - 1)))	CONLEV = 0 => V <sub>LCD_OUT</sub> = 0.61V <sub>LCD</sub>
			CONLEV = 31 => V <sub>LCD_OUT</sub> = V <sub>LCD</sub>

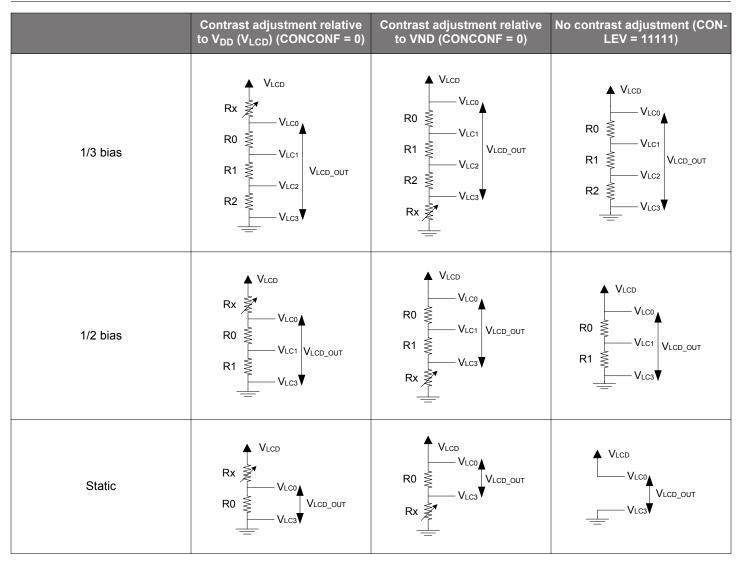

Note: Reset value is maximum contrast

**Table 33.5. LCD Contrast Function** 

CONCONF	Function
0	Contrast is adjusted relative to V <sub>DD</sub> (V <sub>LCD</sub> )
1	Contrast is adjusted relative to Ground

Table 33.6. LCD Principle of Contrast Adjustment for Different Bias Settings

R0 = R1 = R2 = R3 in the figure, while Rx is adjusted by changing the CONLEV bits.

#### 33.3.5 V<sub>LCD</sub> Selection

By default, the LCD driver runs on main external power ( $V_{LCD} = V_{DD}$ ), see the following table. An internal boost circuit can be enabled by setting VBOOSTEN in CMU\_LCDCTRL and selecting the boosted voltage by setting VLCDSEL in LCD\_DISPCTRL. This will boosts  $V_{LCD}$  to  $V_{BOOST}$ .  $V_{BOOST}$  can be selected in the range of 3.0 V – 3.6 V by configuring VBLEV in LCD\_DISPCTRL. Note that the boost circuit is not designed to operate with the selected boost voltage,  $V_{BOOST}$ , smaller than  $V_{DD}$ . The boost circuit can boost the  $V_{LCD}$  up to 3.6 V when  $V_{DD}$  is as low as 2.0 V.

When using the voltage booster, the LCD\_BEXT pin must be connected through a 1  $\mu$ F capacitor to VSS, and the LCD\_BCAP\_P and LCD\_BCAP\_N pins must be connected to each other through a 22 nF capacitor.

It is also possible to connect a dedicated power supply to the LCD module. The LCD external power supply must be connected to the LCD\_BEXT pin and VLCDSEL in LCD\_DISPCTRL must be set. In this mode, the voltage booster should be disabled.

Table 33.7. LCD V<sub>LCD</sub>

VLCDSEL	Mode	V <sub>LCD</sub>
0	VDD	V <sub>DD</sub> (same as main external power)
1	VBOOST	Voltage booster/External V <sub>DD</sub>

#### 33.3.6 VBOOST Control

The boost voltage is configurable. By programming the VBLEV bits in LCD\_DISPCTRL, the boost voltage level can be adjusted between 3.0V and 3.6V.

The boost circuit will use an update frequency given by the VBFDIV bits in CMU\_LCDCTRL, see the following table. It is possible to adjust the frequency to optimize performance for all kinds of LCD panels (large capacitors may require less frequent updates, while small capacitors may require more frequent updates). A lower update frequency would in general lead to smaller current consumption.

Table 33.8. LCD V<sub>BOOST</sub> Frequency

VBFDIV	V <sub>BOOST</sub> Update Frequency
000	LFACLK
001	LFACLK/2
010	LFACLK/4
011	LFACLK/8
100	LFACLK/16
101	LFACLK/32
110	LFACLK/64
111	LFACLK/128

#### 33.3.7 Frame Rate

It is important to choose the correct frame rate for the LCD display. Normally, the frame rate should be between 30 and 100 Hz. A frame rate below 30 Hz may lead to flickering, while a frame rate above 100 Hz may lead to ghostering and unnecessarily high power consumption.

### 33.3.7.1 Clock Selection and Prescaler

The LFACLK is prescaled to LFACLK<sub>LCDpre</sub> in the CMU. The available prescaler settings are:

- LFCLK16: LFACLK<sub>LCDpre</sub> = LFACLK/16
- LFCLK32: LFACLK<sub>LCDpre</sub> = LFACLK/32
- LFCLK64: LFACLK<sub>LCDpre</sub> = LFACLK/64
- LFCLK128: LFACLK<sub>LCDpre</sub> = LFACLK/128

In addition to selecting the correct prescaling, the clock source can be selected in the CMU.

To use this module, the LE interface clock must be enabled in CMU\_HFCORECLKEN0, in addition to the module clock.

### 33.3.7.2 Frame Rate Division Register

The frame rate is set in the CMU by programming the frame rate division bits FDIV in CMU\_LCDCTRL. This setting should not be changed while the LCD driver is running. The equation for calculating the resulting frame rate is:

$$\mathsf{LFACLK}_\mathsf{LCD} = \frac{\mathsf{LFACLK}_\mathsf{LCDpre}}{1 + \mathsf{FDIV}}$$

Table 33.9. LCD Frame Rate Conversion Table

				Resulti	ng Frame r	ate, CLK <sub>FRA</sub>	<sub>ME</sub> (Hz)			
MUX Mode	Frame-Rate Rormula		<sub>LCDpre</sub> = 2 Hz	LFACLK <sub>L</sub>		LFACLK <sub>L(</sub>	<sub>CDpre</sub> = 0.5 Iz	LFACLK <sub>LCDpre</sub> = 0.25 kHz		
		Min	Max	Min	Max	Min	Max	Min	Max	
Static	LFACLK <sub>LCD</sub> /2	128	1024	64	512	32	256	16	128	
Duplex	LFACLK <sub>LCD</sub> /4	64	512	32	256	16	128	8	64	
Triplex	LFACLK <sub>LCD</sub> /6	43	341	21	171	11	85	5	43	
Quadruplex	LFACLK <sub>LCD</sub> /8	32	256	16	128	8	64	4	32	
Sextaplex	LFACLK <sub>LCD</sub> /12	21.33	170.67	10.67	85.33	5.33	42.67	267	21.33	
Octaplex	LFACLK <sub>LCD</sub> /16	16	128	8	64	4	32	2	16	

Table settings: Min: FDIV = 7, Max: FDIV = 0

#### 33.3.8 Data Update

The LCD Driver logic that controls the output waveforms is clocked on LFACLK<sub>LCDpre</sub>. The LCD data and Control Registers are clocked on the HFCORECLK. To avoid metastability and unpredictable behavior, the data in the Segment Data (SEGDn) registers must be synchronized to the LCD driver logic. Also, it is important that data is updated at the beginning of an LCD frame since the segment waveform depends on the segment data and a change in the middle of a frame may lead to a DC-component in that frame. The LCD driver has dedicated functionality to synchronize data transfer to the LCD frames. The synchronization logic is applied to all data that need to be updated at the beginning of the LCD frames:

- · LCD\_SEGDn
- LCD\_AREGA
- LCD AREGB
- · LCD BACTRL

The different methods to update data are controlled by the UDCTRL bits in LCD\_CTRL.

Table 33.10. LCD Update Data Control (UDCTRL) Bits

UDCTRL	Mode	Description
00	REGULAR	The data transfer is controlled by SW and data synchronization is initiated by writing data to the buffers. Data is transferred as soon as possible, possibly creating a frame with a DC component on the LCD.
01	FCEVENT	The data transfer is done at the next event triggered by the Frame Counter (FC). See Section 33.3.10 Frame Counter (FC) for details on how to configure the Frame Counter. Optionally, the Frame Counter can also generate an interrupt at every event.
10	FRAMESTART	The data transfer is done at frame-start.

### 33.3.9 Direct Segment Control (DSC)

It is possible to gain direct control over the bias levels for each SEG/COM line by setting DSC in LCD\_CTRL, overwriting the BIAS settings in LCD\_DISPCTRL. The SEG lines bias levels can be set in SEGD0-SEGD3, while the COM line bias levels can be set in SEGD4. To represent the different bias levels, 2-bits per SEG lines are needed. For example, SEG0's bias levels can be set using SEGD0[1:0], and SEG1 can be controlled through SEGD0[3:2] etc. Bias level encoding is shown in the table below.

Table 33.11. DSC BIAS Encoding

SEGD	Mode	Bias setting					
00	Static	Static (2 levels)					
01	Half Bias	1/2 Bias (3 levels)					
10	Third Bias	1/3 Bias (4 levels)					
11	Fourth Bias	1/4 Bias (5 levels)					

#### 33.3.10 Frame Counter (FC)

The Frame Counter is synchronized to the LCD frame start and will generate an event after a programmable number of frames. An FC event can trigger:

- · LCD ready interrupt
- Blink (controlling the blink frequency)
- · Next state in the Animation State Machine
- Data update if UDCTRL = 01

The Frame Counter is a down counter. It is enabled by writing FCEN in LCD\_BACTRL. Optionally, the Frame Counter can be prescaled so that the Frame Counter is decremented at:

- · Every frame
- · Every second frame
- · Every fourth frame
- · Every eight frame

This is controlled by the FCPRESC in LCD\_BACTRL, see the following table.

Table 33.12. FCPRESC

FCPRESC	Mode	Description	General Equation
00	Div1	CLK <sub>FRAME</sub> /1	
01	Div2	CLK <sub>FRAME</sub> /2	$CLK_{FC} = \frac{CLK_{FRAME}}{2FCPRESC}$
10	Div4	CLK <sub>FRAME</sub> /4	$\frac{\text{CLN}_{FC} - \frac{1}{2}\text{FCPRESC}}{1}$
11	Div8	CLK <sub>FRAME</sub> /8	

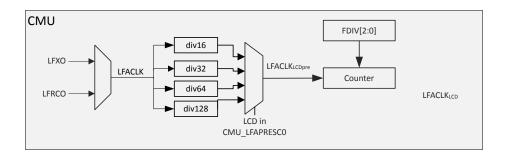

The top value for the Frame Counter is set by FCTOP in LCD\_BACTRL. Every time the frame counter reaches zero, it is reloaded with the top value, and at the same time an event, which can cause an interrupt, data update, blink, or an animation state transition is triggered.

$$CLK_{EVENT} = \frac{CLK_{FC}}{1 + FCTOP[5:0]}Hz$$

The previous equation shows how to set-up the LCD event frequency. In this example, the frame rate is 64Hz, and the LCD event frequency should be set-up to 2 seconds.

- Write FCPRESC to 3 => CLK<sub>FC</sub> = 8Hz (0.125 seconds)
- Write FCTOP to 15 => CLK<sub>EVENT</sub> = 0.5Hz (2 seconds)

If higher resolution is required, configure a lower prescaler value and increase the FCPRESC in LCD\_BACTRL accordingly (e.g. FCPRESC = 2, FCTOP = 31).

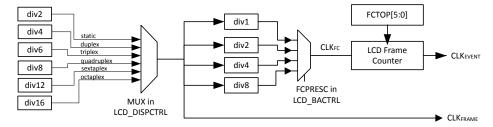

Figure 33.43. LCD Clock System in LCD Driver

#### 33.3.11 LCD Interrupt

The LCD interrupt can be used to synchronize data update. The FC interrupt flag is set at every LCD Frame Counter Event, which must be set-up separately. The interrupt is enabled by setting FC bit in LCD\_IEN.

#### 33.3.12 Blink, Blank, and Animation Features

#### 33.3.12.1 Blink

The LCD driver can be configured to blink, alternating all enabled segments between on and off. The blink frequency is given by the CLK<sub>EVENT</sub> frequency, see 33.3.10 Frame Counter (FC). See 33.3.8 Data Update for details regarding synchronization of the blink feature. The FC must be on for blink to work.

#### 33.3.12.2 Blank

Setting BLANK in LCD\_BACTRL will output the "OFF" waveform on all enabled segments, effectively blanking the entire display. Writing the BLANK bit to zero disables the blanking and segment data will be output as normal. See 33.3.8 Data Update for details regarding synchronization of blank.

#### 33.3.12.3 Animation State Machine

11

Reserved

Reserved

The Animation State Machine makes it possible to enable different animations without updating the data registers, allowing specialized patterns running on the LCD panel while the microcontroller remains in Low Energy Mode and thus saving power consumption. The animation feature is available on 8 segments multiplexed with LCD\_COM0. The 8 segments can be either segments 0 to 7 or 8 to 15, depending on ALOC in LCD\_BACTRL. The animation is implemented as two programmable 8 bits registers that are shifted left or right every other Animation state for a total of 16 states.

The shift operations applied to the shift registers are controlled by AREGASC and AREGBSC in LCD\_BACTRL as shown in the following table. Note also that the FC must be on for animation to work, as it is the FC event that drives the animation state machine.

AREGNSC, n = A or B

No Shift operation

No Shift operation

SHIFTLEFT Animation register is shifted left (LCD\_AREGA is shifted every odd state, LCD\_AREGB is shifted every even state)

SHIFTRIGHT Animation register is shifted right (LCD\_AREGA is shifted every odd state, LCD\_AREGB is shifted every even state)

Table 33.13. LCD Animation Shift Register

The two registers are either OR'ed or AND'ed to achieve the displayed animation pattern. This is controlled by ALOGSEL in LCD\_BACTRL as shown in the following table. In addition, the regular segment data SEGD0[7:0] / SEGD0[15:8] is OR'ed with the animation pattern to generate the resulting output.

ALOGSEL Mode Description

O AND LCD\_AREGA and LCD\_AREGB are AND'ed together

OR LCD\_AREGA and LCD\_AREGB are OR'ed together

Table 33.14. LCD Animation Pattern

Each state is displayed one CLK<sub>EVENT</sub> period, see 33.3.10 Frame Counter (FC). By reading ASTATE in LCD\_STATUS, software can identify which state that is currently active in the state sequence. Note that the shifting operation is performed on internal registers that are not accessible in SW (when reading LCD\_AREGA and LCD\_AREGB, the data that was original written will also be read back). The SW must utilize the knowledge about the current state (ASTATE) to calculate what is currently output. ASTATE is cleared when LCD\_AREGA or LCD\_AREGB are updated with new values. See the following table for an example.

Table 33.15. LCD Animation Example

ASTATE	LCD_AREGA	LCD_AREGB	Resulting Data				
0	11000000	11000000	11000000				
1	01100000	11000000	11100000				
2	01100000	01100000	01100000				
3	00110000	01100000	01110000				
4	00110000	00110000	00110000				
5	00011000	00110000	00111000				
6	00011000	00011000	00011000				
7	00001100	00011000	00011100				

ASTATE	LCD_AREGA	LCD_AREGB	Resulting Data
8	00001100	00001100	00001100
9	00000110	00001100	00001110
10	00000110	00000110	00000110
11	0000011	00000110	00000111
12	0000011	0000011	0000011
13	10000001	0000011	10000011
14	1000001	1000001	10000001
15	11000000	1000001	11000001

In the table, AREGASC = 10, AREGBSC = 10, ALOGSEL = 1 and the resulting data is to be displayed on segment lines 7-0 or 15-8 multiplexed with LCD\_COM0.

SEGD0[7:0] / SEGD0[15:8]

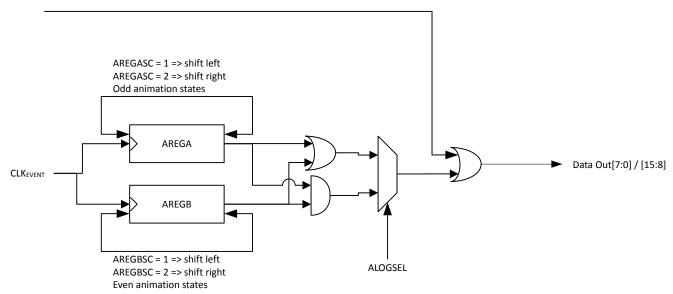

Figure 33.44. LCD Block Diagram of the Animation Circuit

### **LCD Animation Enable Example**

- · Write data into the animation registers LCD\_AREGA, LCD\_AREGB
- · Enable the correct shift direction (if any)
- · Decide which logical function to perform on the registers
  - ALOGSEL = 0: Data\_out = LCD\_AREGA & LCD\_AREGB
  - ALOGSEL = 1:Data\_out = LCD\_AREGA | LCD\_AREGB
- Configure the right animation period (CLK<sub>EVENT</sub>)
- Enable the animation pattern and frame counter (AEN = 1, FCEN = 1)

#### **LCD Animation Dependence Example**

For updating data in the LCD while it is running an animation, and the new animation data depends on the pattern visible on the LCD, see the following example.

- Enable the LCD interrupt (the interrupt will be triggered simultaneously as the Animation State machine changes state)
- In the interrupt handler, read back the current state (ASTATE)
- · Knowing the current state of the Animation State Machine makes it possible to calculate what data that is currently output
- Modify data as required (Data will be updated at the next Frame Counter Event). It is important that new data is written before the next Frame Counter Event.

#### 33.3.13 LCD in Low Energy Modes

As long as the LFACLK is running (EM0-EM2), the LCD controller continues to output LCD waveforms according to the data that is currently synchronized to the LCD Driver logic. In addition, the following features are still active if enabled:

- · Animation State Machine
- Blink
- · LCD Event Interrupt

#### 33.3.14 Register Access

Since this module is a Low Energy Peripheral, and runs off a clock which is asynchronous to the HFCORECLK, special considerations must be taken when accessing registers. Please refer to 5.2.4 Access to Low Energy Peripherals (Asynchronous Registers) for a description on how to perform register accesses to Low Energy Peripherals.

# 33.4 Register Map

The offset register address is relative to the registers base address.

Access	₩ X										R N		Z M																			
Name									DSC																					UDCTRL		N E

				5
Bit	Name	Reset	Access	Description
31:24	Reserved	To ensure o	compatibility	with future devices, always write bits to 0. More information in 2.1 Conven
23	DSC	0	RW	Direct Segment Control
	This bit enables	direct control over	bias levels fo	or each SEG/COM line.
	Value			Description
	0			DSC disable
	1			DSC enable
22:3	Reserved	To ensure o	compatibility	with future devices, always write bits to 0. More information in 2.1 Conven
2:1	UDCTRL	0x0	RW	Update Data Control
	These bits contro	ol how data from th	ne SEGDn re	gisters are transferred to the LCD driver.
	Value	Mode		Description
	0	REGULAR		The data transfer is controlled by SW. Transfer is performed as soon as possible
	1	FCEVENT		The data transfer is done at the next event triggered by the Frame Counter
	2	FRAMESTA	ART	The data transfer is done continuously at every LCD frame start
0	EN	0	RW	LCD Enable
	When this bit is s	set, the LCD driver	is enabled a	nd the driver will start outputting waveforms on the com/segment lines.

# 33.5.2 LCD\_DISPCTRL - Display Control Register

Offset			Bit Position
0x004	31 30 30 29 28 27 27 27	22 23 24 25 25 27 27 29 29 29 29 29 29 29 29 29 29 29 29 29	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

### 34. FPUEH - Floating Point Unit Exception Handler

### 34.1 Functional Description

The Floating Point Unit, FPU, included in the Cortex-M4 has a set of status flags indicating mathematical errors that cause floating-point exceptions. Available status flags are:

- FPIOC FPU invalid operation.
- · FPDZC FPU divide-by-zero exception.
- · FPUFC FPU underflow exception.
- · FPOFC FPU overflow exception.
- · FPIDC FPU input denormal exception.
- · FPIXC FPU inexact exception.

Refer to the ARM Cortex-M4 Devices Generic User Guide for more information about the FPU status flags. The FPU exception handler, FPUEH, monitors these status flags and sets the corresponding interrupt flag in FPUEH\_IF when they are asserted. An interrupt request will be set if the corresponding bit in FPUEH\_IEN is set. The interrupt flags can also be set and cleared using the FPUEH\_IFS and FPUEH\_IFC registers, respectively.

**Note:** Before the FPUEH interrupt flags can be cleared, the corresponding status flag in the FPU has to be cleared. Refer to ARM Cortex-M4 Devices Generic User Guide for information on how to do this.

### 34.2 Register Map

The offset register address is relative to the registers base address.

### 35. Revision History

### 35.1 Revision 1.10

January 31, 2017

Updated formatting.

Removed mention of 20 mV hysteresis in 27. VCMP - Voltage Comparator, since this value can vary from 20 mV and is specified in the device data sheet.

Removed the Internal Data Flow sections from 15.4.4.2.2.11 Generic Isochronous OUT Data Transfers Using Periodic Transfer Interrupt Feature and 15.4.4.2.3.14 Generic Periodic IN Data Transfers Using the Periodic Transfer Interrupt Feature.

#### 35.2 Revision 1.00

July 2nd, 2014

Removed "Preliminary" markings.

Updated block diagram.

Updated current numbers and voltage supply range.

Moved chapter "Device Revision" to section 3.

#### 35.3 Revision 0.60

August 29th, 2013

Updated LETIMER Async Support in Reflex Producers table.

Updated the I2C Clock Mode table and added the Maximum Data Hold Time formula.

Added the minimum HFPERCLK requirement for I2C Slave Operation.

Added a new register access type RW1H.

Updated RMU Reset Cause Register Interpretation table.

Updated the register description of CMU\_CTRL.

Updated CMU\_CALCNT description.

Updated DMA\_CHENC register description.

Updated description of number of wait-states for Immediate Synchronization.

Updated description of the Excite Phase timing in LESENSE.

Updated the LETIMER PRS description.

Updated OPAMP description.

Updated the EM4 with RTC and Data Retention with BURTC description.

Added LPFMODE recommendation for the ADC Input Filtering.

Updated the LETIMER description for usage in EM3.

Updated the RTC description for usage in EM3.

Updated WRITEONCE bitfield description in MSC WRITECMD register.

Updated the MSC\_TIMEBASE register description.

Updated the DMA and USB DMA access description.

Updated trademark, disclaimer and contact information.

Other minor corrections.

## 35.4 Revision 0.51

May 10th, 2013

Fixed missing "MHz" in relation to the core clock frequency.

## 35.5 Revision 0.50

April 26th, 2013

Initial preliminary revision.

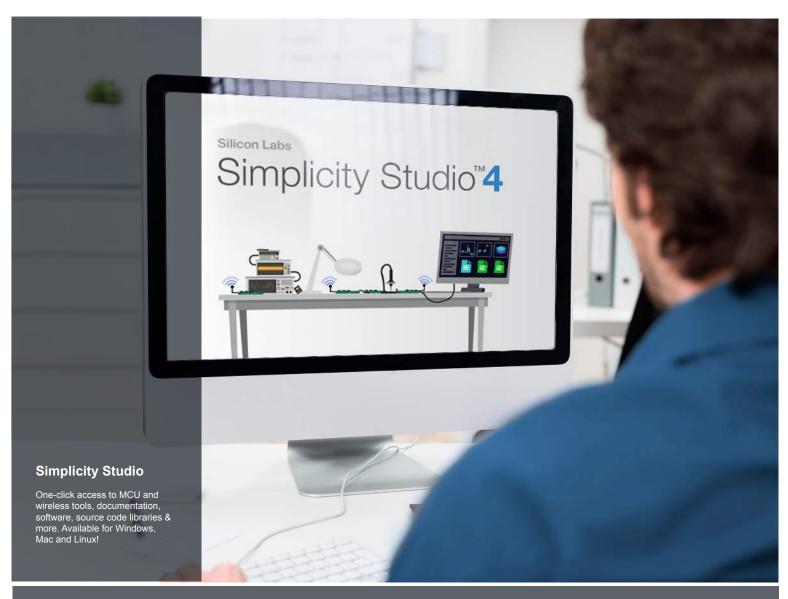

# 36. Abbreviations

This section lists abbreviations used in this document.

Table 36.1. Abbreviations

Abbreviation	Description
ACMP	Analog Comparator
ADC	Analog to Digital Converter
АНВ	AMBA Advanced High-performance Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".
APB	AMBA Advanced Peripheral Bus. AMBA is short for "Advanced Microcontroller Bus Architecture".
ALE	Address Latch Enable
AUXHFRCO	Auxiliary High Frequency RC Oscillator.
СС	Compare / Capture
CLK	Clock
CMD	Command
CMU	Clock Management Unit
CTRL	Control
DAC	Digital to Analog Converter
DBG	Debug
DMA	Direct Memory Access
DRD	Dual Role Device
DTI	Dead Time Insertion
EBI	External Bus Interface
EFM	Energy Friendly Microcontroller
EM	Energy Mode
EM0	Energy Mode 0 (also called active mode)
EM1 to EM4	Energy Mode 1 to Energy Mode 4 (also called low energy modes)
EMU	Energy Management Unit
ENOB	Effective Number of Bits
FS	Full-speed
GPIO	General Purpose Input / Output
HFRCO	High Frequency RC Oscillator
HFXO	High Frequency Crystal Oscillator
HW	Hardware
12C	Inter-Integrated Circuit interface
LCD	Liquid Crystal Display
LESENSE	Low Energy Sensor Interface
LETIMER	Low Energy Timer

Abbreviation	Description
LEUART	Low Energy Universal Asynchronous Receiver Transmitter
LFRCO	Low Frequency RC Oscillator
LFXO	Low Frequency Crystal Oscillator
LS	Low-speed
MAC	Media Access Controller
NVIC	Nested Vector Interrupt Controller
OPA/OPAMP	Operational Amplifier
OSR	Oversampling Ratio
OTG	On-the-go
PCNT	Pulse Counter
PGA	Programmable Gain Array
PHY	Physical Layer
PRS	Peripheral Reflex System
PSRR	Power Supply Rejection Ratio
PWM	Pulse Width Modulation
RC	Resistance and Capacitance
RMU	Reset Management Unit
RTC	Real Time Clock
SAR	Successive Approximation Register
SOF	Start of Frame
SPI	Serial Peripheral Interface
SW	Software
THD	Total Harmonic Distortion
UART	Universal Asynchronous Receiver Transmitter
USART	Universal Synchronous Asynchronous Receiver Transmitter
USB	Universal Serial Bus
VCMP	Voltage supply Comparator
WDOG	Watchdog timer
XTAL	Crystal

#### Disclaimer

Silicon Labs intends to provide customers with the latest, accurate, and in-depth documentation of all peripherals and modules available for system and software implementers using or intending to use the Silicon Labs products. Characterization data, available modules and peripherals, memory sizes and memory addresses refer to each specific device, and "Typical" parameters provided can and do vary in different applications. Application examples described herein are for illustrative purposes only. Silicon Labs reserves the right to make changes without further notice and limitation to product information, specifications, and descriptions herein, and does not give warranties as to the accuracy or completeness of the included information. Silicon Labs shall have no liability for the consequences of use of the information supplied herein. This document does not imply or express copyright licenses granted hereunder to design or fabricate any integrated circuits. The products are not designed or authorized to be used within any Life Support System without the specific written consent of Silicon Labs. A "Life Support System" is any product or system intended to support or sustain life and/or health, which, if it fails, can be reasonably expected to result in significant personal injury or death. Silicon Labs products are not designed or authorized for military applications. Silicon Labs products shall under no circumstances be used in weapons of mass destruction including (but not limited to) nuclear, biological or chemical weapons, or missiles capable of delivering such weapons.
