MICROCHIP

TC7660H

HIGH FREQUENCY 7660 DC-TO-DC VOLTAGE CONVERTER

FEATURES

- **Pin Compatible with 7660, High Frequency Performance DC-to-DC Converter**
- **Low Cost, Two Low Value External Capacitors Required .... (1.0µF)**
- **Converts +5V Logic Supply to ±5V System**
- **Wide Input Voltage Range .... 1.5V to 10V**
- **Voltage Conversion 99.7%**
- **Power Efficiency 85%**
- **Available in 8-Pin SOIC and 8-Pin PDIP Packages**

GENERAL DESCRIPTION

The TC7660H is a pin-compatible, high frequency upgrade to the Industry standard TC7660 charge pump voltage converter. It converts a +1.5V to +10V input to a corresponding – 1.5V to – 10V output using only two low-cost capacitors, eliminating inductors and their associated cost, size and EMI.

The TC7660H operates at a frequency of 120kHz (versus 10kHz for the TC7660), allowing the use of 1.0µF external capacitors. Oscillator frequency can be reduced (for lower supply current applications) by connecting an external capacitor from OSC to ground.

The TC7660H is available in 8-pin DIP and small outline (SOIC) packages in commercial and extended temperature ranges.

PIN CONFIGURATION (DIP and SOIC)

NC	1	8	V$^+$
CAP$^+$	2	7	OSC
GND	3	6	LOW VOLTAGE (LV)
CAP$^-$	4	5	V$_{OUT}$

Symbol	Parameter	Test Conditions	Min	Typ	Max	Unit
I^+	Supply Current	$R_L = \infty$	—	0.46	1.0	mA
V_H^+	Supply Voltage Range, High	Min $\leq T_A \leq$ Max, R_L = 5kΩ, LV Open	3	—	10	V
V_L^+	Supply Voltage Range, Low	Min $\leq T_A \leq$ Max, R_L = 5kΩ, LV to GND	1.5	—	3.5	V
R_{OUT}	Output Source Resistance	I_{OUT} = 20mA, $T_A = 25°C$	—	55	80	Ω
		I_{OUT} = 20mA, $0°C \leq T_A \leq +70°C$ (C Device)	—	—	95	Ω
		I_{OUT} = 20mA, − 40°C $\leq T_A \leq$ +85°C (E Device)	—	—	110	Ω
		V^+ = 2V, I_{OUT} = 3mA, LV to GND $0°C \leq T_A \leq +70°C$	—	150	250	Ω
F_{OSC}	Oscillator Frequency		—	120	—	kHz
P_{EFF}	Power Efficiency	I_{OUT} = 10mA, Min $\leq T_A \leq$ Max	81	85	—	%
V_{EFF}	Voltage Efficiency	$R_L = \infty$	99	99.7	—	%

NOTES: 1. Connecting any input terminal to voltages greater than V+ or less than GND may cause destructive latch-up. It is recommended that no inputs from sources operating from external supplies be applied prior to "power up" of the TC7660H.
   2. Derate linearly above 50°C by 5.5mW/°C.

Figure 1. TC7660H Test Circuit

Detailed Description

The TC7660H contains all the necessary circuitry to implement a voltage inverter, with the exception of two external capacitors, which may be inexpensive 1.0µF non-polarized capacitors. Operation is best understood by considering Figure 2, which shows an idealized voltage inverter. Capacitor C_1 is charged to a voltage, V^+, for the half cycle when switches S_1 and S_3 are closed. (Note: Switches S_2 and S_4 are open during this half cycle.) During the second half cycle of operation, switches S_2 and S_4 are closed, with S_1 and S_3 open, thereby shifting capacitor C_1 negatively by V^+ volts. Charge is then transferred from C_1 to C_2, such that the voltage on C_2 is exactly V^+, assuming ideal switches and no load on C_2.
Figure 2. Idealized Charge Pump Inverter

To improve low-voltage operation, the LV pin should be connected to GND. For supply voltages greater than 3.5V, the LV terminal **must be left open to ensure latch-up-proof operation and prevent device damage**.

Theoretical Power Efficiency Considerations

In theory, a capacitative charge pump can approach 100% efficiency if certain conditions are met:

(1) The drive circuitry consumes minimal power.

(2) The output switches have extremely low ON resistance and virtually no offset.

(3) The impedances of the pump and reservoir capacitors are negligible at the pump frequency.

The TC7660H approaches these conditions for negative voltage multiplication if large values of C_1 and C_2 are used. **Energy is lost only in the transfer of charge between capacitors if a change in voltage occurs.** The energy lost is defined by:

$$E = 1/2 \, C_1 \, (V_1{}^2 - V_2{}^2)$$

V_1 and V_2 are the voltages on C_1 during the pump and transfer cycles. If the impedances of C_1 and C_2 are relatively high at the pump frequency (refer to Figure 1), compared to the value of R_L, there will be a substantial difference in voltages V_1 and V_2. Therefore, it is not only desirable to make C_2 as large as possible to eliminate output voltage ripple, but also to employ a correspondingly large value for C_1 in order to achieve maximum efficiency of operation.

Do's and Don'ts

• Do not exceed maximum supply voltages.

• Do not connect LV terminal to GND for supply voltages greater than 3.5V.

• Do not short circuit the output to V^+ supply for voltages above 5.5V for extended periods; however, transient conditions including start-up are okay.

• When using polarized capacitors in the inverting mode, the + terminal of C_1 must be connected to pin 2 of the TC7660H and the + terminal of C_2 must be connected to GND Pin 3.

Simple Negative Voltage Converter

Figure 3 shows typical connections to provide a negative supply where a positive supply is available. A similar scheme may be employed for supply voltages anywhere in the operating range of +1.5V to +10V, keeping in mind that pin 6 (LV) is tied to the supply negative (GND) only for supply voltages below 3.5V.

The output characteristics of the circuit in Figure 3 are those of a nearly ideal voltage source in series with 70Ω. Thus, for a load current of – 10 mA and a supply voltage of +5V, the output voltage would be – 4.3V.

The dynamic output impedance of the TC7660H is due, primarily, to capacitive reactance of the charge transfer capacitor (C_1). Since this capacitor is connected to the output for only 1/2 of the cycle, the equation is:

$$X_C = \frac{2}{2\pi f\, C_1} = 2.12\Omega,$$

where f = 150kHz and C_1 = 1.0μF.

*NOTES: 1. $V_{OUT} = -n\, V^+$ for 1.5V $\le V^+ \le$ 10V
Figure 3. Simple Negative Converter

Paralleling Devices

Any number of TC7660H voltage converters may be paralleled to reduce output resistance (Figure 4). The reservoir capacitor, C_2, serves all devices, while each device requires its own pump capacitor, C_1. The resultant output resistance would be approximately:

$$R_{OUT} = \frac{R_{OUT}\ (\text{of TC7660H})}{n\ (\text{number of devices})}$$

Figure 4. Increased Output Voltage by Cascading Devices

Cascading Devices

The TC7660H may be cascaded as shown in (Figure 4) to produce larger negative multiplication of the initial supply voltage. However, due to the finite efficiency of each device, the practical limit is probably 10 devices for light loads. The output voltage is defined by:

$$V_{OUT} = -n\ (V_{IN})$$

where n is an integer representing the number of devices cascaded. The resulting output resistance would be approximately the weighted sum of the individual TC7660H R_{OUT} values.

Changing the TC7660H Oscillator Frequency

It may be desirable in some applications (due to noise or other considerations) to increase or decease the oscillator frequency. This can be achieved by overdriving the oscillator from an external clock, as shown in Figure 6. In order to prevent possible device latch-up, a 1kΩ resistor must be used in series with the clock output. In a situation where the designer has generated the external clock frequency using TTL logic, the addition of a 10kΩ pull-up resistor to V^+ supply is required. Note that the pump frequency with external clocking, as with internal clocking, will be 1/2 of the clock frequency. Output transitions occur on the positive-going edge of the clock.
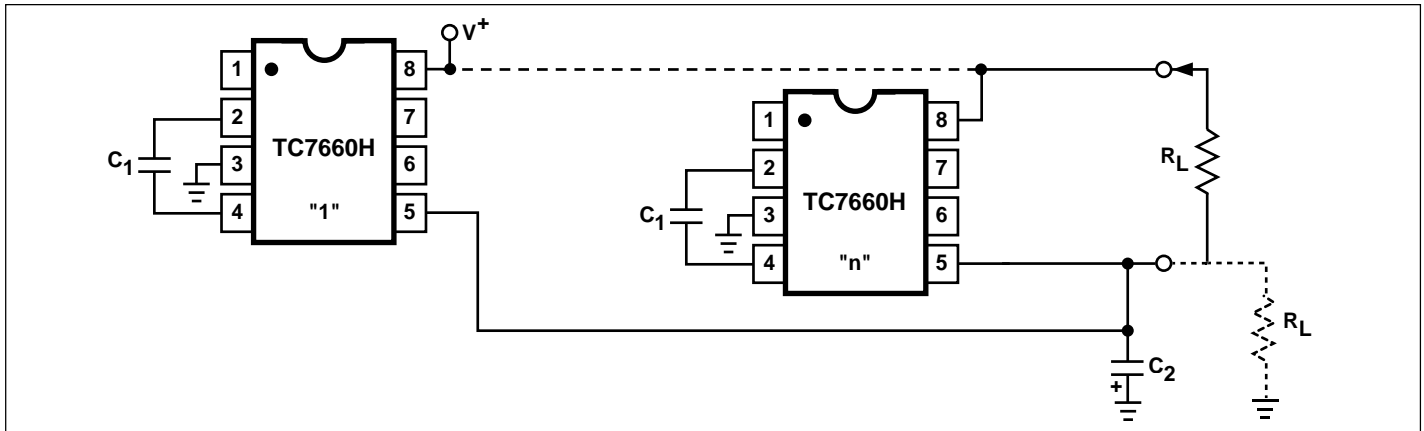

Figure 5. Paralleling Devices Lowers Output Impedance

Figure 6. External Clocking

Positive Voltage Multiplication

The TC7660H may be employed to achieve positive voltage multiplication using the circuit shown in Figure 7. In this application, the pump inverter switches of the TC7660H are used to charge C_1 to a voltage level of $V^+ - V_F$ (where V^+ is the supply voltage and V_F is the forward voltage drop of diode D_1). On the transfer cycle, the voltage on C_1 plus the supply voltage (V^+) is applied through diode D_2 to capacitor C_2. The voltage thus created on C_2 becomes $(2 V^+) - (2 V_F)$, or twice the supply voltage minus the combined forward voltage drops of diodes D_1 and D_2.

The source impedance of the output (V_{OUT}) will depend on the output current, but for $V^+ = 5V$ and an output current of 10mA, it will be approximately 60Ω.
Figure 7. Positive Voltage Multiplier

Combined Negative Voltage Conversion and Positive Supply Multiplication

Figure 8 combines the functions shown in Figures 3 and 8 to provide negative voltage conversion and positive voltage multiplication simultaneously. This approach would be, for example, suitable for generating +9V and –5V from an existing +5V supply. In this instance, capacitors C_1 and C_3 perform the pump and reservoir functions, respectively, for the generation of the negative voltage, while capacitors C_2 and C_4 are pump and reservoir, respectively, for the multiplied positive voltage. There is a penalty in this configuration which combines both functions, however, in that the source impedances of the generated supplies will be somewhat higher due to the finite impedance of the common charge pump driver at pin 2 of the device.

Figure 8. Combined Negative Converter and Positive Multiplier

TC7660H

Efficient Positive Voltage Multiplication/Conversion

Since the switches that allow the charge pumping operation are bidirectional, the charge transfer can be performed backwards as easily as forwards. Figure 9 shows a TC7660H transforming –5V to +5V (or +5V to +10V, etc.). The only problem here is that the internal clock and switch-drive section will not operate until some positive voltage has been generated. An initial inefficient pump, as shown in Figure 9, could be used to start this circuit up, after which it will bypass the diode and resistor shown dotted in Figure 9.
