

FEATURES

- Single-ended and differential input capability
- User-friendly interface connection
- Optimized EMI suppression filter assembled on board

GENERAL DESCRIPTION

The SSM2335 is a fully integrated, single-chip, mono Class-D audio amplifier. It is designed to maximize performance for mobile phone applications. The application circuit requires a minimum of external components and operates from a single 2.5 V to 5.5 V supply. It is capable of delivering 3 W of continuous output power with less than 1% THD + N driving a 3 Ω load from a single 5.0 V supply.

The SSM2335 comes with a differential mode input port and a high efficiency, full H-bridge at the output that enables direct coupling of the audio power signal to the loudspeaker. The differential mode input stage allows for canceling of common-mode noise.

The part also features a high efficiency, low noise output modulation scheme that requires no external LC output filters when attached to an inductive load. Filterless operation also helps to decrease distortion due to the nonlinearities of output LC filters.

This data sheet describes how to configure and use the SSM2335 evaluation board to test the SSM2335. It is recommended that this data sheet be read in conjunction with the [SSM2335](#) data sheet, which provides more detailed information about the specifications, internal block diagrams, and application guidance for the amplifier IC.

EVALUATION BOARD DESCRIPTION

The SSM2335 evaluation board carries a complete application circuit for driving a loudspeaker. Figure 1 shows the top view of the evaluation board, and Figure 2 shows the bottom view.

REVISION HISTORY

5/09—Revision 0: Initial Version

EVALUATION BOARD HARDWARE

INPUT CONFIGURATION

On the left side of the PCB is a 4-pin header, H2 (see Figure 1). This is used to feed the audio signal into the board.

If the input audio signal is differential (IN+ and IN–), use the two center pins of H2. In this case, either the top or bottom pin should be connected to the source/signal ground.

For a single-ended audio input only two pins of H2 are used. One pin is for the ground and the other pin is for either IN+ or IN–. If IN+ is used, place a jumper between Pin 3 and Pin 4 of H2, shorting IN– to ground. If IN– is used, place the jumper between Pin 1 and Pin 2 of H2, connecting IN+ to the ground.

The 2-pin header, J1, is used to turn the SSM2335 amplifier on or off. Putting a jumper across J1 shuts down the SSM2335 so that only a minimum current (about 20 nA) is drawn from the power supply. Removing the jumper puts the SSM2335 in normal operating mode.

OUTPUT CONFIGURATION

The output connector, H4, is located on the right side of the board (see Figure 1). H4 drives a loudspeaker whose impedance should be no less than 3 Ω.

The SSM2335 does not require any external LC output filters due to a low noise modulation scheme. However, if the speaker length is >10 cm, it is recommended that a ferrite bead (B1 and B2) be placed near each output pin of the SSM2335 to reduce electromagnetic interference (EMI), as shown in the schematic in Figure 4. On the board, there are two inductors, L1 and L2, that are not loaded and not required for normal operation. Some users may want to replace the ferrite beads with these inductors to evaluate applications with specific EMI vs. audio performance constraints.

If L1 and L2 are loaded, the ferrite beads, B1 and B2, must be removed. As an aid, a properly tuned ferrite bead based EMI filter is assembled at the output terminals of the device.

For optimal performance, as specified in the SSM2335 data sheet (in particular, for THD and SNR), remove the entire EMI filter, short across the ferrite bead terminals, and open the capacitor terminals.

POWER SUPPLY CONFIGURATION

The 2-pin header (H1) must be used to power the board, which accepts a 2.5 V ~ 5.5 V dc power supply. Care must be taken to connect the dc power with correct polarity and voltage.

Polarity and Voltage

The wrong power supply polarity or overvoltage may permanently damage the board permanently. The maximum peak current is approximately 0.33 A when driving an 8 Ω load and when the input voltage is 5 V.

COMPONENT SELECTION

Selecting the proper components is the key to achieving the performance required at the budgeted cost.

Input Coupling Capacitor Selection—C1 and C2

The input coupling capacitors, C1 and C2, should be large enough to couple the low frequency signal components in the incoming signal and small enough to filter out unnecessary low frequency signals. For music signals, the cutoff frequency chosen is often between 20 Hz and 30 Hz. The value of the input capacitor is calculated by

$$C = 1/(2\pi Rf_c)$$

where:

$R = 20 \text{ k}\Omega + R_{EXT}$ (the external resistor used to fine-tune the desired gain; on the schematics (see Figure 4), this is the 0 Ω resistor at the input pins).

f_c is the cutoff frequency.

Output Ferrite Beads—B1 and B2

The output beads, B1 and B2, are necessary components for filtering out the EMI caused at the switching output nodes when the length of the speaker wire is greater than 10 cm. The penalty for using ferrite beads for EMI filtering is slightly worse noise and distortion performance at the system level due to the nonlinearity of the beads.

Ensure that these beads have enough current conducting capability while providing sufficient EMI attenuation. The current rating needed for an 8 Ω load is approximately 420 mA, and impedance at 100 MHz must be $\geq 120 \Omega$. In addition, the lower the dc resistance (DCR) of these beads, the better for minimizing their power consumption.

Table 1 describes the recommended beads.

1033AS-4R7M	Toko	4.7	680	0.31	3.8 × 3.8 × 1

Output Shunting Capacitors

There are two output shunting capacitors, C3 and C4, that work with the B1 and B2 ferrite beads or with the L1 and L2 inductors, if they are used. Use small size (0603 or 0402), multilayer ceramic capacitors that are made of X7R or COG (NPO) materials. Note that the capacitors can be used in pairs: a capacitor with small capacitance (up to 100 pF) plus a capacitor with a larger capacitance (less than 1 nF). This configuration provides thorough EMI reduction for the entire frequency spectrum. For BOM cost reduction and capable performance, a single capacitor of approximately 470 pF can be used.

Output Inductors—L3 and L4

If you prefer using inductors for the purpose of EMI filtering at the output nodes, choose inductance that is <2.2 μH for these inductors. The higher the inductance, the lower the EMI is at the output. However, the cost and power consumption by the inductors are higher. Using 0.47 μH to 2.2 μH inductors is recommended, and the current rating needs >600 mA (saturation current) for an 8 Ω load. Table 2 shows the recommended inductors. Note that these inductors are not populated on the evaluation board.

PCB LAYOUT GUIDELINES

To keep the EMI under the allowable limit and to ensure that the amplifier chip operates under the temperature limit, PCB layout is critical in application design. Figure 3 shows the preferred layout for the SSM2335 evaluation board.

Figure 3. Preferred PCB Layout for the SSM2335 Evaluation Board

Layer Stacks and Grounding

The stack-up for the evaluation board is a 4-layer structure.

- Top layer—component layer with power and output copper land and ground copper pouring.
- Second layer—dedicated ground plane.
- Third layer—dedicated power plane.
- Bottom layer—bottom layer with ground copper pouring.

Component Placement and Clearance

Place all related components except decoupling capacitors on the same side as the SSM2335 and as close as possible to the chip to avoid vias (see Figure 5).

Place decoupling capacitors on the bottom side and close to the GND pin (see Figure 7).

Top Layer Copper Land and Ground Pouring

The output peak current of this amplifier is more than 1 A; therefore, PCB traces should be wide (>2 mm) to handle the high current. For the best performance, use symmetrical copper lands as large as space allows (instead of traces) for the output pins (see Figure 3).

Pour ground copper on the top side and use many vias to connect the top layer ground copper to the dedicated ground plane. The copper pouring on the top layer serves as both the EMI shielding ground plane and the heat sink for the SSM2335.

The SSM2335 works well only if these techniques are implemented in the PCB design to keep EMI and the amplifier temperature low.

GETTING STARTED

To ensure proper operation, carefully follow Step 1 through Step 4.

1. If a jumper is on J1, remove the jumper to activate the amplifier.
2. Connect the load to the audio output connector, H4.
3. Connect the audio input to the board, either in differential mode or single-ended mode, depending on the application.
4. Connect the power supply with the proper polarity and voltage.

WHAT TO TEST

When implementing the SSM2335 evaluation board, test the board for the following?

- Electromagnetic interference (EMI)—connect wires for the speakers, making sure they are the same length as the wires required for the actual application environment; then complete the EMI test.
- Signal-to-noise ratio (SNR).
- Output noise—make sure to use an A-weighted filter to filter the output before reading the measurement meter.
- Maximum output power.
- Distortion.
- Efficiency.

ORDERING GUIDE

Model	Description
EVAL-SSM2335Z ¹	Evaluation Board

¹ Z = RoHS Compliant Part.

ESD CAUTION

ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.
