

FEATURES

- Organized as a high density 512k x 16 bit Stik™
- Fast access time of 85 ns
- Unlimited write cycles
- Employs popular JEDEC standard 80-position SIMM connector
- Full $\pm 10\%$ operating range
- Read cycle time equals write cycle time
- Ultra-low standby current $< 10 \mu\text{A}$
- Suitable for battery-backed applications

PIN ASSIGNMENT

80-PIN SIP STIK

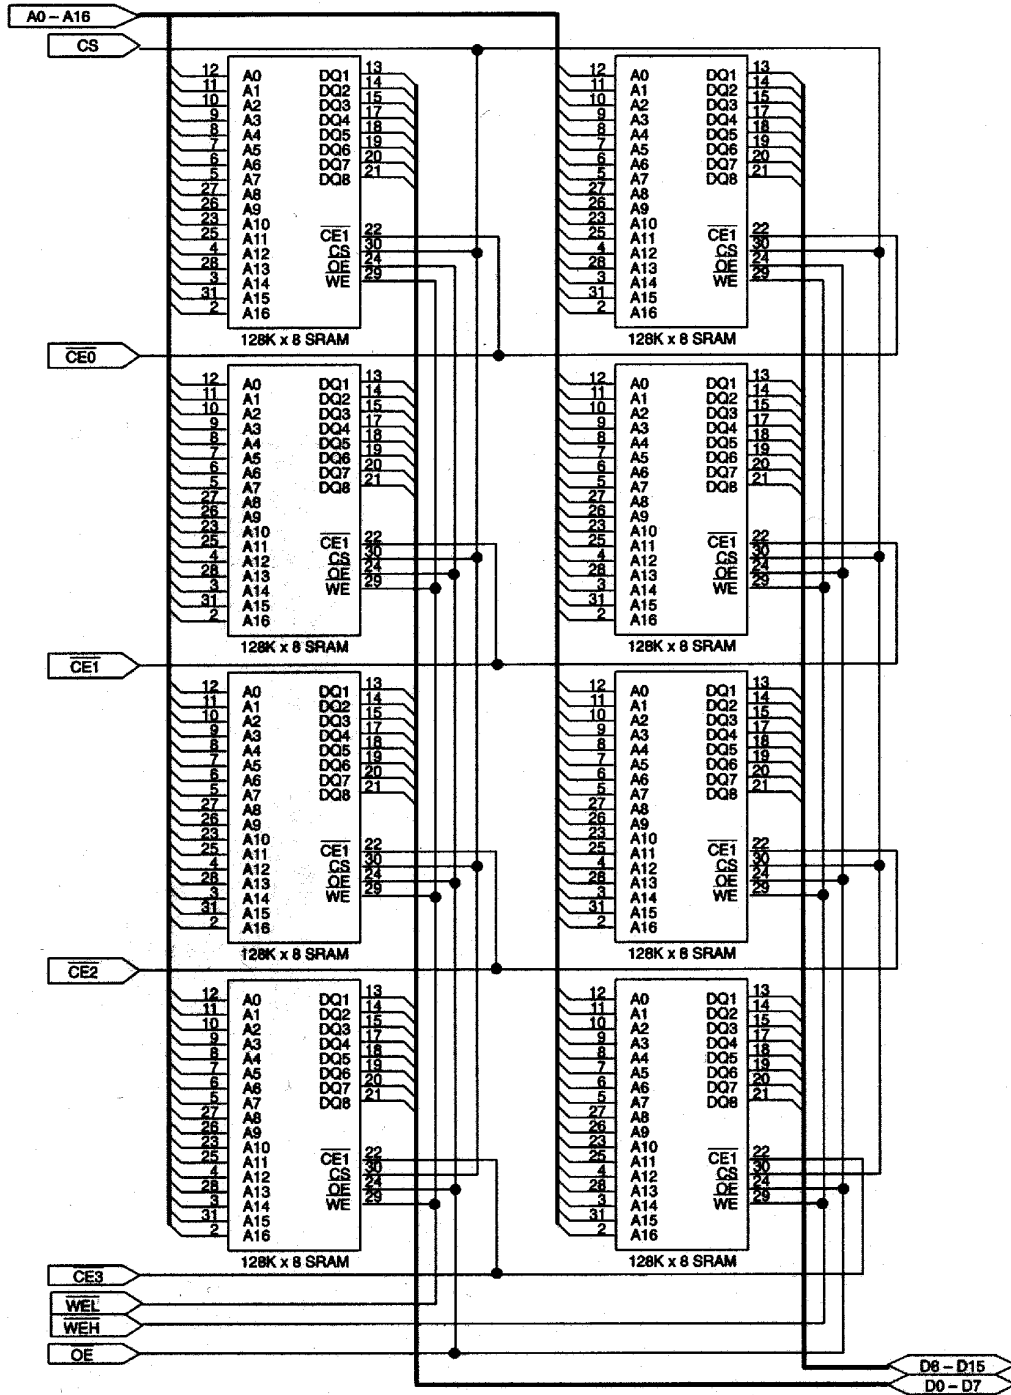

DESCRIPTION

The DS2229 is an 8,388,608-bit low-power fully static Random Access Memory organized as a 524,888 word by 16 bits using CMOS technology. The device employs the popular JEDEC standard 80-pin SIMM connection scheme with no additional circuitry required. The device operates from a single power supply with a voltage input of 4.5 to 5.5 volts. The Chip Enable inputs ($\overline{\text{CE0}}$, $\overline{\text{CE1}}$, $\overline{\text{CE2}}$, $\overline{\text{CE3}}$) are used for device selection and can be used in order to achieve the minimum standby current mode which facilitates battery backup. The device provides a fast access time of 85 ns. The DS2229 maintains TTL levels over input voltage range 4.5V to 5.5V. The DS2229 is JEDEC pin compatible (see Figure 1) with flash EEPROM memory SIMM boards of similar density.

READ CYCLE Figure 5

WRITE CYCLE 1 Figure 6

WRITE CYCLE 2 Figure 7

NOTES:

1. A write occurs during the overlap of a low $\overline{CE0} - \overline{CE3}$, a high CS, and a low \overline{WE} . A write begins at the latest transition among $\overline{CE0} - \overline{CE3}$ going low, CS going high, and \overline{WE} going low. A write ends at the earliest transition among $\overline{CE0} - \overline{CE3}$ going high, CS going low and \overline{WE} going high. t_{WP} is measured from the beginning of write to the end of write.
2. \overline{WE} is high for a read cycle.
3. t_{DS} ends and t_{DH} begins at the earliest transition among $\overline{CE0} - \overline{CE3}$ going high.
4. t_{WR} is measured from the earliest of $\overline{CE0} - \overline{CE3}$ or \overline{WE} going high or CS going low to the end of write cycle.
5. CS controls address buffer, \overline{WE} buffer, $\overline{CE0} - \overline{CE3}$ buffer, \overline{OE} buffer and D_{IN} buffer. If CS controls data retention mode, V_{IN} levels (address, \overline{WE} , \overline{OE} , $\overline{CE0} - \overline{CE3}$, I/O) can be in the high impedance state. If $\overline{CE0} - \overline{CE3}$ controls data retention mode, CS must be $CS \geq V_{CC} - 0.2V$ or $0V < CS < 0.2V$. The other input levels (address, \overline{WE} , \overline{OE} , I/O) can be in the high impedance state.
6. If $\overline{CE0} - \overline{CE3}$ goes low simultaneously with \overline{WE} going low or after \overline{WE} going low, the outputs remain in a high impedance state.
7. If $\overline{CE0} - \overline{CE3}$ is low and CS is high during this period, I/O pins are in the output state. Therefore, the input signals of the opposite phase to the outputs must not be applied to them.
8. This parameter is sampled and not 100% tested.
9. Only one \overline{CE} active during any read or write cycle.
