

The Future of Analog IC Technology

DESCRIPTION

The MP3385 is a step-up controller with 4 regulated current channels designed to drive WLED arrays for middle and large-size LCD panel backlighting applications.

The MP3385 uses peak current mode, PWM control architecture for system loop regulation. It drives an external MOSFET to boost up the output voltage from a 4.5V to 33V input supply.

It employs an I^2C digital interface and can flexibly set the operation and protection modes, including dimming mode, dimming current and dimming ratio, OCP, OVP, LED short protection threshold, and the switching frequency. For easy application use and board debugging, the MP3385 detects and automatically disables the unused LED strings during start-up to avoid charging the output to the OVP threshold.

The MP3385 achieves 1.8% current matching between each string. The low regulation voltage on the LED current sources improves efficiency and reduces power loss in order to achieve a higher current output.

The MP3385 supports analog, PWM, and combined analog and PWM dimming modes to meet different application requirements. Full protection features include OCP, OTP, UVP, OVP, LED short/open protection, and inductor/diode short protection.

The MP3385 is available in a QNF-20 (4mm x 4mm) and a TSSOP20-EP package.

FEATURES

- 4-String, Max 300mA/String WLED Driver
- 4.5V to 33V Input Voltage Range
- 80V Abs. Rating for Each String
- 1.8% Current Matching Accuracy for Each String
- Unused Channel Auto-Detection Function during Start-Up
- 100kHz-900kHz Programmable Switching **Frequency**
- Multiple Dimming Modes Selected by I^2C Interface:
	- 1. Direct PWM Dimming Mode
	- 2. Internal Fixed 23kHz PWM Dimming Mode
	- 3. Analog Dimming Mode by Input Pulse
	- 4. Internal Analog Dimming Mode
	- 5. Mixed Dimming Mode by Input Pulse
	- 6. Internal Mixed Dimming Mode
- 2%-100% Programmable Full Scale Current with 8-Bit Resolution
- 0%-100% LED Dimming Range with 10-Bit Resolution for Internal Dimming Mode
- Cascading Capability with a Single Power Source
- 18V to 80V Over-Voltage Protection, 2V/Step
- 0.15V to 0.5V Latch-Off/Recoverable OCP Protection Threshold, 50mV/Step
- Recoverable Thermal Shutdown Protection

APPLICATIONS

- Desktop LCD Flat Panel Displays
- All-in-One
- 2D/3D LCD TV

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS" and "The Future of Analog IC Technology" are registered trademarks of Monolithic Power Systems, Inc.

ABSOLUTE MAXIMUM RATINGS (1)

Recommended Operating Conditions **(3)**

Thermal Resistance **(4)** *θJA θJC* QFN-20 (4mm x 4mm).............42........9.....°C/W TSSOP20-EP.........40........8....°C/W

NOTES:

- 1) Exceeding these ratings may damage the device.
- 2) The maximum allowable power dissipation is a function of the $maximum$ junction temperature T_J (MAX), the junction-toambient thermal resistance θ_{JA} , and the ambient temperature T_A . The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = (T_J $(MAX)-T_A)/\theta_{JA}$. Exceeding the maximum allowable power dissipation will produce an excessive die temperature, causing the regulator to go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- 3) The device is not guaranteed to function outside of its operating conditions.
- 4) Measured on JESD51-7, 4-layer PCB.

ELECTRICAL CHARACTERISTICS

V_{IN} = 12V, V_{EN} = 5V, T_A = 25°C, unless otherwise noted.

PIN FUNCTIONS

FUNCTIONAL BLOCK DIAGRAM

OPERATION

The MP3385 employs a programmable constant frequency, peak current mode step-up converter with 4 regulated current channels to drive an array of 4 strings of white LEDs. It has an I^2C interface for easy communication that flexibly sets the operation modes.

Internal 6V Regulator

The MP3385 includes an internal linear regulator (VCC). When VIN is greater than 6.5V, the regulator outputs a 6V power supply to the external MOSFET switch gate driver and the internal control circuitry. The VCC voltage drops to 0V when the chip shuts down. The MP3385 features under-voltage lockout (UVLO). The chip is disabled until VCC exceeds the UVLO threshold. The UVLO hysteresis is approximately 340mV.

System Start-Up

When enabled, the MP3385 checks the topology connection first. The chip monitors the over-voltage protection (OVP) pin to see if the Schottky diode is connected or if the boost output is shorted to GND. An OVP voltage higher than 2.5V allows the chip to switch normally. Otherwise, the switching is disabled. The MP3385 checks additional safety limits including LED open/short protection, UVLO, over-temperature protection (OTP), and overcurrent protection (OCP) after passing the OVP test. If all the protection tests pass, the chip starts boosting the step-up converter with an internal soft start.

Step-Up Converter

At the beginning of each switching cycle, the internal clock turns on the external MOSFET. (In normal operation, the minimum turn-on time is around 150ns.) A stabilizing ramp is added to the output of the current sense amplifier to prevent sub-harmonic oscillations for duty cycles greater than 50%. This result is fed into the PWM comparator. When the summed voltage reaches the output voltage of the error amplifier (V_{COMP}), the external MOSFET turns off.

The output voltage of the internal error amplifier is an amplified signal of the difference between

the reference voltage and the feedback voltage. Automatically, the converter chooses the lowest active LEDX voltage to provide a high enough bus voltage to power all the LED arrays.

If the feedback voltage drops below the reference, the output of the error amplifier increases. This results in more current flowing through the MOSFET, thus increasing the power delivered to the output. This forms a closed loop that regulates the output voltage.

Under light-load operation, especially in the case of $V_{\text{OUT}} \approx V_{\text{IN}}$, the converter runs in pulseskipping mode where the MOSFET turns on for a minimum on time, and then the converter discharges the power to the output for the remaining period. The external MOSFET remains off until the output voltage needs to be boosted again.

Dimming Control

The MP3385 provides flexible dimming methods according to the dimming mode settings below.

1) PWM Dimming Mode:

MODE bits = 00. The LED current duty cycle directly follows the PWM input signal duty cycle when INTERFACE = 0. The IC works in internal PWM dimming mode, and the LED current duty cycle is set by the internal registers 03H and 04H when INTERFACE = 1. The internal dimming frequency is fixed at 23kHz.

2) Analog Dimming Mode:

MODE bits = 01. The LED current amplitude follows the duty cycle of the input PWM signal when INTERFACE = 0. The IC works in internal analog dimming mode (the LED current amplitude follows the internal register value of $03H$ and $04H$) if INTERFACE = 1.

3) Mixed Dimming Mode:

There are two transfer points from analog to PWM dimming (25% or 50%) set by the I^2C interface.

If MODE bits are set to 10 (when the dimming duty cycle is larger than the 25% threshold), the IC works in analog dimming mode. Otherwise, the IC works in PWM dimming mode, and the LED current follows the PWM ratio. If MODE bits are set to 11 (when the dimming duty cycle is larger than the 50% threshold), the IC works in analog dimming mode. Otherwise, the IC works in PWM dimming mode.

In mixed dimming mode (when INTERFACE is set to 0), the LED current amplitude is proportional to the ratio of the external PWM signal if the duty cycle of PWM is larger than the transfer point (25% or 50%). The LED current amplitude is fixed to 100% brightness while the LED current duty is equal to the input PWM ratio (if the duty cycle of PWM is lower than the transfer point). When INTERFACE is set to 1, the LED current amplitude and the duty cycle is set by registers 03H and 04H.

Regardless of the INTERFACE setting (1 or 0), the LED current frequency is fixed to 23kHz in mixed dimming mode when the duty cycle < the transfer point (25% or 50%).

In analog and mixed dimming mode, to avoid noise at the small dimming ratio, the IC turns off the current sources if the current is less than 1.2% times the full scale current.

For external analog and mixed dimming mode, the smallest pulse width of the PWM signal is limited to 2µs to avoid noise interruption.

Operation Switching Frequency

The operation frequency of the converter can be changed by the OSC resistor and the FS0-3 bit in register 01H. The switching frequency covers 100kHz to 900kHz through the I^2C register bits when a 100kΩ resistor is connected to OSC. This optimizes the size of the external components and system efficiency.

Open-String Protection

Open-string protection is achieved through the OVP pin and the LED(1 to 4) pins. If one or more strings are open, the respective LEDX pins are pulled to ground; the IC keeps charging the output voltage until it reaches the over-voltage protection (OVP) threshold. If the OVP point has been triggered, the chip stops switching and marks the strings which have an

LEDX pin voltage lower than 206mV. Once marked, the remaining LED strings force the output voltage back into tight regulation. The string with the largest voltage drop determines the output regulation.

The MP3385 always attempts to light at least one string. If all strings are open, the MP3385 shuts down the step-up converter. The strings remain in this marked state until the chip resets.

Unused LED String Auto-Detection

For the MP3385, if an LED string is open or unused before start-up, automatically the IC detects and marks off the open channel to avoid the output charging to the OVP value. This function avoids start-up failure, which is caused by the LED short string mis-protection due to OVP triggering. This is helpful for application use and test board debugging. The unused LED string auto-detection function is disabled if the OVP point is changed by the I^2C after EN and VIN power on, and I^2C is active.

In addition, the MP3385 disables the unused LED string by disabling the corresponding register control bit for each 4-channel current source. In some applications, if less than 4 LED strings are needed, the unused LED current sources can be disabled by setting the LED1/2/3/4 bit to 0 in register 00H.

Short-String Protection

The MP3385 monitors the LEDX pin voltages to determine if a short-string fault has occurred. If one or more strings are shorted, the respective LEDX pins tolerate high-voltage stress. If an LEDX pin voltage is higher than the protection threshold, which can be programmable by LEDS0/1/2 bits in 01H, this condition triggers the detection of a short-string fault. When a short-string fault remains for longer than 10ms, the fault string is marked off and disabled. Once a string is marked off, it disconnects from the output voltage loop until VIN or EN re-starts.

Cycle-by-Cycle Current Limit

To prevent the external components exceeding the current stress rating, the IC has cycle-bycycle current limit protection. The limit value is programmable from 150mV to 500mV by OCP0/1/2 bits in register 05H. When the current exceeds the current limit value, the IC latches

MPS Proprietary Information. Patent Protected. Unauthorized Photocopy and Duplication Prohibited. © 2017 MPS. All Rights Reserved.

off until the power is reset or ENABLE is toggled when operating in latch-off mode (if OCPM = 0). The device re-starts when the current drops below the current limit again (if $OCPM = 1$).

Short Inductor/Diode Protection

When the external inductor or diode is shorted, the IC provides protection by detecting the current flowing through the power MOSFET. When the current sense voltage across the sense resistor (connected between IS and GND) hits the current protection threshold and lasts for 4 switching cycles, the IC stops switching and latches.

Thermal Shutdown Protection

To prevent the IC from operating at exceedingly high temperatures, thermal shutdown is implemented to detect the silicon die temperature. When the die temperature exceeds the upper threshold (T_{ST}) , the IC shuts down. The IC resumes normal operation when the die temperature drops below the lower threshold. Typically, the hysteresis value is 25° C.

Fault Flag Output and Fault Register Indicator

FT remains in an open-drain condition when the LED driver is operating in a normal condition. It is connected to VCC by an external 100kΩ resistor and pulled to logic high when there is no fault. FT goes to logic low if a fault occurs. Meanwhile, set the corresponding fault bit in register 03H to 1.

I ²C Interface Register Description

I ²C Chip Address:

After the start condition, the I^2C compatible master sends a 7-bit address followed by

an eighth read (Read: 1) or write (Write: 0) bit. The following bit indicates the register address to/from which the data will be written/read (see Figure 3).

APPLICATION INFORMATION

Selecting the Switching Frequency

The operation frequency of the converter depends on both the resistor at OSC and the FS0-3 bit in register 01H. If a 100kΩ resistor is selected for Rosc (connected to OSC), the switching frequency is set from 100kHz-900kHz by the I²C interface. 0001b-1001b corresponds to 100kHz-900kHz respectively. Table 8 shows the list of switching frequencies.

Without the I²C interface, an oscillator resistor on OSC sets the internal oscillator frequency for the step-up converter according to Equation (1):

$$
F_{\text{sw}}(\text{kHz}) = \frac{40000}{R_{\text{osc}}(\text{k}\Omega)}\tag{1}
$$

For R_{OSC} = 100kΩ, the switching frequency is set to 400kHz.

Setting the LED Current

The current of each LED string is set through the current setting resistor on ISET and the full scale LED current setting bits ILED0-7 in the 02H table. When the INTERFACE bit in 00H is 0, the LED current is dependent on the input PWM dimming duty cycle. The setting formula is calculated using Equation (2) and Equation (3):

$$
ILED(mA) = \frac{1.98V}{R_{\text{ISET}}(k\Omega)} * K_{\text{FullScale}} * 10200
$$
 (2)

When INTERFACE bit in 00H is 1,

$$
ILED(mA) = \frac{1.98V * K_{\text{DIM}}}{R_{\text{1SET}}(k\Omega)} * K_{\text{FulScale}} * 10200
$$
 (3)

 $K_{FullScale}$ is the ratio, which is set by the full scale LED current setting bits ILED0-7 in the 02H table. K_{DIM} is the ratio, which is set by the dimming current setting bits DIM0-9 in 03H and 04H.

Without the $I²C$ interface, the current of each LED string is set through the resistor on ISET according to Equation (4):

$$
ILED(mA) = \frac{1.98V}{R_{\text{ISET}}(k\Omega)} * 0.2294 * 10200
$$
 (4)

For R_{ISET} = 46.4kΩ, the LED current is set to 100mA. Please do NOT leave ISET open.

Selecting the Input Capacitor

The input capacitor reduces the surge current drawn from the input supply and the switching noise from the device. The input capacitor impedance at the switching frequency should be less than the input source impedance to prevent the high-frequency switching current from passing through to the input. Use ceramic capacitors with X5R or X7R dielectrics for their low ESR and small temperature coefficients. For most applications, use a 4.7μF ceramic capacitor in parallel with a 220µF electrolytic capacitor.

Selecting the Inductor and Current Sensing Resistor

A larger value inductor results in less ripple current, resulting in lower peak inductor current, which reduces stress on the N-channel MOSFET. However, the larger value inductor has a larger physical size, a higher series resistance, and a lower saturation current. Choose an inductor that does not saturate under the worst-case load conditions. Select the minimum inductor value to ensure that the boost converter works in continuous conduction mode (CCM) with high efficiency and good EMI performance.

Calculate the required inductance value using Equation (5) and Equation (6):

$$
L \geq \frac{\eta \times V_{\text{OUT}} \times D \times (1-D)^2}{2 \times f_{\text{SW}} \times I_{\text{LOAD}}}
$$
 (5)

$$
=1-\frac{V_{\text{IN}}}{V_{\text{OUT}}}\tag{6}
$$

Where V_{IN} and V_{OUT} are the input and output voltages, f_{SW} is the switching frequency; I_{LOAD} is the LED load current, and η is the efficiency.

 \overline{D}

Usually, the switching current is used for peakcurrent-mode control. In order to avoid hitting the current limit, the voltage across the sensing resistor (R_{SENSE}) must be less than 70% of the current-limit voltage (V_{SENSE}) , in worst cases. See Equation (7) and Equation (8):

$$
R_{\text{SENSE}} = \frac{0.7 \times V_{\text{SENSE}}}{I_{\text{L(PEAK)}}}
$$
(7)

$$
I_{L(PEAK)} = \frac{V_{OUT} \times I_{LOAD}}{\eta V_{IN}} + \frac{V_{IN} \times (V_{OUT} - V_{IN})}{2 \times L \times F_{SW} \times V_{OUT}}
$$
(8)

The current limit setting voltage (V_{SENSE}) is set by the OCP0-2 bits in register 05H.

Selecting the Power MOSFET

The MP3385 is capable of driving a wide variety of N-channel power MOSFETS. The critical parameters of selection for a MOSFET are:

- 1. maximum drain-to-source voltage, $V_{DS(MAX)}$
- 2. maximum current, $I_{D(MAX)}$
- 3. on resistance, $R_{DS(ON)}$
- 4. gate-source charge (Q_{GS}) and gate-drain charge (Q_{GD}) , and
- 5. total gate charge (Q_G) .

Ideally, the off-state voltage across the MOSFET is equal to the output voltage. Considering the voltage spike when it turns off, $V_{DS(MAX)}$ should be greater than 1.5x the output voltage.

The maximum current through the power MOSFET occurs at the minimum input voltage and the maximum output power. The maximum RMS current through the MOSFET is given by Equation (9) and Equation (10):

$$
I_{\text{RMS}(\text{MAX})} = I_{\text{IN}(\text{MAX})} \times \sqrt{D_{\text{MAX}}}
$$
(9)

$$
D_{\text{MAX}} \approx \frac{V_{\text{OUT}} - V_{\text{IN(MIN)}}}{V_{\text{OUT}}}
$$
 (10)

The current rating of the MOSFET should be greater than $1.5 \times I_{RMS}$

The on resistance of the MOSFET determines the conduction loss. See Equation (11):

$$
P_{\text{cond}} = I_{\text{RMS}}^{2} \times R_{\text{DS (on)}} \times k \tag{11}
$$

Where k is the temperature coefficient of the MOSFET.

The switching loss is related to Q_{GD} and Q_{GS} , which determine the commutation time. Q_{GS1} is the charge between the threshold voltage and the plateau voltage when a driver charges the gate, which can be read in the chart of V_{GS} vs. Q_G of the MOSFET datasheet. Q_{GD} is the charge during the plateau voltage. These two parameters are needed to estimate turn-on and turn-off losses. See Equation (12):

$$
P_{SW} = \frac{Q_{GS1} \times R_G}{V_{DR} - V_{TH}} \times V_{DS} \times I_{IN} \times f_{SW} +
$$

$$
\frac{Q_{GD} \times R_G}{V_{DR} - V_{PLT}} \times V_{DS} \times I_{IN} \times f_{SW}
$$
 (12)

Where V_{TH} is the threshold voltage, V_{PLT} is the plateau voltage; R_G is the gate resistance, and V_{DS} is the drain-source voltage. Please note that calculating the switching loss is the most difficult part in the loss estimation. The formula above provides a simplified equation. For more accurate estimates, the equation becomes much more complex. The total gate charge (Q_G) is used to calculate the gate-drive loss. See Equation (13):

$$
P_{DR} = Q_G \times V_{DR} \times f_{SW}
$$
 (13)

Where V_{DR} is the drive voltage.

Selecting the Output Capacitor

The output capacitor keeps the output voltage ripple small and ensures feedback loop stability. The output capacitor impedance must be low at the switching frequency. Ceramic capacitors with X7R dielectrics are recommended for their low ESR characteristics. For most applications, a 4.7μF ceramic capacitor in parallel with a 22μF electrolytic capacitor will suffice.

Setting the Over-Voltage Protection

Open-string protection is achieved through the detection of the voltage on the OVP pin. In some cases, an LED string failure results in the feedback voltage always at zero. The part then keeps boosting the output voltage higher and higher. If the output voltage reaches the programmed OVP threshold, the protection will be triggered.

To ensure the chip functions properly, an appropriate OVP voltage is needed. The recommended OVP point is about 1.1 to 1.2x higher than the output voltage for normal operation. If the OVP pin is connected to the anode of the LED load, the OVP protection

MP3385 Rev. 1.02 www.MonolithicPower.com entitled and Duplication Prohibited 22 metals are metals and Duplication Prohibited 22 MPS Proprietary Information. Patent Protected. Unauthorized Photocopy and Duplication Prohibited. © 2017 MPS. All Rights Reserved.

voltage is set by the OVP0-4 bits in register 05H. It is not recommended to set the OVP value higher than 80V, considering the LED return pin voltage rating.

If the MP3385 is applied for >80V output voltage an external extension, connect a proper resistor (R_{OVP}) between the anode of the LED and OVP pin to change the over-voltage point of the output (V_{OVP}) . V_{OVP} calculation with R_{ovP} is given with Equation (14):

$$
V_{\text{OVP}}(V) = \frac{R_{\text{OVP}}(k\Omega) + 1600}{40} \times 1.9
$$
 (14)

Where OVP0-4 bit in register 05H is the set default.

Expanding LED Channels

The MP3385 expands the number of LED channels by using two or three ICs in parallel. To connect two ICs for a total of 8 LED strings, tie the VCC pins of the master IC and the slave IC together to power the slave IC internal logic circuitry. Tie the COMP pins of the slave IC and the master IC together to regulate the voltage of all 8 strings LEDs. The slave IC MOSFET driving

signals are not used; the boost converter can be driven only by the master IC. Do NOT leave ISENSE of the slave IC floating; tie it to ground. Apply the EN and DIM signals to both ICs. The master IC's OVP should be higher than the slave IC's OVP.

PCB Layout Guidelines

Efficient PCB layout is critical to reduce EMI noise. For best results, refer to the guidelines below:

1. Make the loop from the external MOSFET, through the output diode and the output capacitor as small and short as possible as they carry a high-frequency pulse current.

2. Separate the power ground (PGND) and signal ground (GND), then connect PGND and GND together. All logic signals refer to the signal ground in order to reduce the noise affection.

3. Place ceramic capacitors for VIN and VCC pins as close as possible.

Note: **Remove the LPF capacitor (C5) when the MP3385 works in direct PWM dimming. Some components value may need to be adjusted for different application condition**
