

# TMC1103

## Triple Video A/D Converter with Clamps

### 8-Bit, 50MSPs

#### Features

- 8-bit resolution
- 50 MspS conversion rate
- Low power: 100mW per channel @ 20 MspS
- Integral track/hold
- Independent Input Clamps
- Independent clock inputs
- Integral and differential linearity error 0.5 LSB
- Differential phase 0.7 degree
- Differential gain 1.8%
- Single +5V power supply
- Three-state TTL/CMOS-compatible outputs
- Low cost

#### Applications

- Video digitizing (composite and Y-C)
- VGA and CCD digitizing
- LCD projection panels
- Image scanners
- Personal computer video boards
- Multimedia systems
- Low cost, high speed data conversion

#### Description

Incorporated into the TMC1103 are three analog-to-digital (A/D) converters, each with an independent clock, reference voltage and input clamp. Analog signals are converted to Triple 8-bit digital words at sample rates up to 50 MspS (Megasamples per second) per channel.

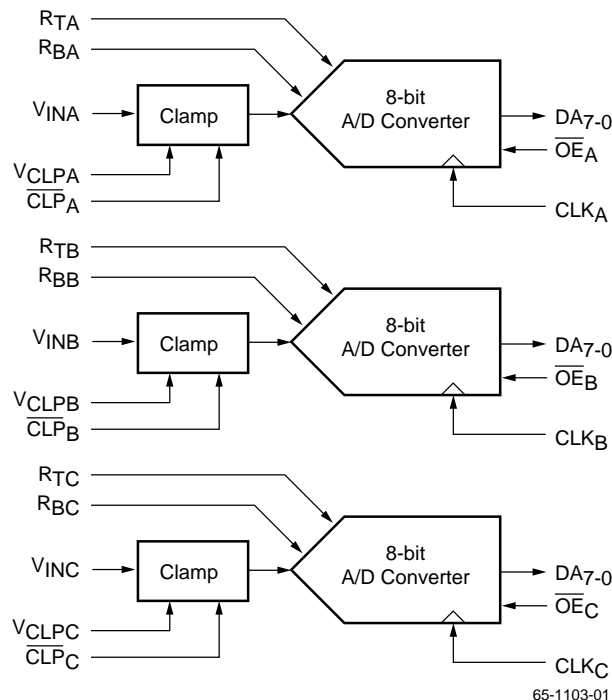

Integral Track/Hold circuits deliver excellent performance on signals with full-scale spectral components up to 12 MHz. Innovative two-step conversion architecture and

submicron CMOS technology reduce typical power dissipation to 100 mW per converter.

Power is derived from a single +5 Volt power supply. Outputs are three-state outputs and TTL/CMOS-compatible.

TMC1103 package is a 80-lead Metric Quad Flat Pack (MQFP). Performance specifications are guaranteed from 0°C to 70°C.

#### Block Diagram

## Circuit Function

Within the TMC1103 are three 8-bit A/D converters, each employing two-step architecture to convert an analog input to a digital output at rates up to 50 Msps. Input signals are held in integral track/hold stages during the conversion process. Operation is pipelined, with one input sample taken and one output word provided for each  $CLK_X$  cycle.

Each of the three converters function identically. In the following descriptions 'X' refers to a generic input/output or clock where 'X' is equivalent to A, B or C.

The first step in the conversion process is a coarse 4-bit quantization. This determines the range of the subsequent fine 4-bit quantization step. To eliminate spurious codes, the fine 4-bit A/D quantizer output is gray-coded and converted to binary before it is combined with the coarse result to form a complete 8-bit result.

### Analog Input and Voltage References

Each A/D accepts analog signals in the range  $R_{BX}$  to  $R_{TX}$  into digital data. Input signals outside this range produce "saturated" 00h or FFh output codes. The device will not be damaged by signals within the range AGND to  $V_{DDA}$ .

Input range is very flexible and extends from the +5 Volt power supply to ground. Nominal input range is 2 Volts, extending from 0.6V to 2.6V. Characterization and performance is specified over this range. However, the part will function with a full-scale range from 1.0V to 5.0V. A smaller input range may simplify analog signal conditioning circuitry, at the expense of additional noise sensitivity and some reduced differential linearity performance.

External voltage reference sources are connected to the  $R_{TX}$  and  $R_{BX}$  pins.  $R_{BX}$  can be grounded. Within each A/D converter is a reference resistor ladder comprising 255 resistors that are accessed by the TMC1103 comparators.  $R_{TX}$  is connected to the top of the ladder,  $R_{BX}$  to the bottom. Gain and offset errors are directly related to the accuracy and stability of the applied reference voltages.

### Input Clamps

A clamp circuit is connected to the input pin  $V_{INX}$  of each of the three A/D converters. With  $\overline{CLP}_X$  LOW, the input pin is clamped to the voltage at  $V_{CLPX}$ . If  $\overline{CLP}_X$  is HIGH, the input pin is high impedance. Clamping adds an offset voltage to an AC coupled signal to adjust this signal's amplitude to the A/D converter input voltage range.

The analog input is corrected through a  $0.1\mu F$  capacitor to  $V_{INX}$ . The source impedance of the analog source should be less than 50 Ohms. Current pulses through the capacitor over several clamp cycles until the voltage across the capacitor equals the difference between  $V_{CLPX}$  and the voltage at the analog source during the clamping period. When the switch is open, the voltage on the coupling capacitor is added to the analog input, producing a DC offset input signal.

Input Clamp Circuit

65-1103-02

### Digital Inputs and Outputs

Sampling of the applied input signal occurs on the falling edge of the  $CLK_X$  signal (Figure 1). Output data is delayed by  $2\frac{1}{2} CLK_X$  cycles and is valid following the rising edge of  $CLK_X$ . Previous output data remains valid for  $t_{HO}$  (Output Hold Time). New data becomes valid  $t_D$  (Output Delay Time) after this rising edge of  $CLK_X$ .

Whenever the analog input signal is sampled and found to be at a level beyond the A/D conversion range, the output limits at 00h or FFh, as appropriate.

Table 1. A/D Output Coding

Input Voltage	Output
$R_{TX} + 1 \text{ LSB}$	FF
$R_{TX}$	FF
$R_{TX} - 1 \text{ LSB}$	FE
...	...
$R_{BX} + 128 \text{ LSB}$	80
$R_{BX} + 127 \text{ LSB}$	7F
...	...
$R_{BX} + 1 \text{ LSB}$	01
$R_{BX}$	00
$R_{BX} - 1 \text{ LSB}$	00

Note:  $1 \text{ LSB} = (R_{TX} - R_{BX}) / 255$

The outputs of the TMC1103 are CMOS- and TTL-compatible, and are capable of driving four low-power Schottky TTL loads. An Output Enable control,  $\overline{OE}_X$ , places the A/D outputs in a high-impedance state when HIGH. The outputs are enabled when  $\overline{OE}_X$  is LOW.

### Power and Ground

The TMC1103 operates from a single +5 Volt power supply. For optimum performance, an analog ground plane should be placed under the TMC1103 the AGND and DGND pins should be connected to the system analog ground plane.

## Pin Descriptions

Pin Name	Pin Number	Value	Pin Function Description
<b>A/D Converters</b>			
VINA, VINB, VINC	12, 55, 48	RTX to RBX	<b>Analog Inputs.</b> The input voltage conversion range lies between the voltage applied to the RTX and RBX pins.
RTA, RTB, RTC	14, 53, 50	2.6V	<b>Reference Voltage, Top Inputs.</b> DC voltages applied to RTA, RTB and RTC define highest value of VINX.
RBA, RBB, RBC	15, 52, 51	0.6V	<b>Reference Voltage, Bottom Inputs.</b> DC voltages applied to RBA, RBB and RBC define lowest value of VINX.
CLKA, CLKB, CLKC	9, 58, 45	CMOS	<b>Clock Inputs.</b> CMOS-compatible. VINX is sampled on the falling edge of CLKX.
DA7-0	4, 3, 2, 80, 79, 78, 77, 76	CMOS/TTL	<b>Data outputs, Converter A (D7 = MSB).</b> Eight-bit CMOS- and TTL-compatible digital outputs. Valid data is output on the rising edge of CLKX.
DB7-0	63, 64, 65, 66, 67, 68, 69, 70	CMOS/TTL	<b>Data outputs, Converter B (D7 = MSB).</b> Eight-bit CMOS- and TTL-compatible digital outputs. Valid data is output on the rising edge of CLKX.
DC7-0	41, 40, 39, 38, 37, 36, 35, 34	CMOS/TTL	<b>Data outputs, Converter C (D7 = MSB).</b> Eight-bit CMOS- and TTL-compatible digital outputs. Valid data is output on the rising edge of CLKX.
$\overline{OE}A, \overline{OE}B, \overline{OE}C$	5, 62, 42	CMOS	<b>Output Enable Inputs.</b> CMOS-compatible. When LOW, the A/D output is enabled. When HIGH, the output is in a high-impedance state.
<b>Clamps</b>			
VCLPA, VCLPB, VCLPB	16, 17, 18	RTX to RBX	<b>Clamp Reference Voltage.</b> One reference for each clamp. A VINX input is clamped to VCLPX when $\overline{CLP}X$ is low.
$\overline{CLP}A, \overline{CLP}B, \overline{CLP}C$	28, 29, 30	CMOS	<b>Clamp Pulse Inputs.</b> One input for each A/D clamp. When $\overline{CLP}X$ is low, the VINX input is clamped to the VCLPX clamp voltage.
<b>Power</b>			
VDDA	11, 47, 56	+5V	<b>Analog Supply Voltage.</b> +5 Volt power inputs. These should come from the same power source and be decoupled to AGND.
VDD	6, 7, 27, 28, 29, 30, 43, 44, 60, 61	+5V	<b>Digital Supply Voltage.</b> +5 Volt power inputs. These should come from the same power source and be decoupled to AGND.
AGND	13, 49, 54	0.0V	<b>Analog Ground.</b> Ground connections. These pins should be connected to the system analog ground plane.
DGND	16, 17, 18, 19, 20, 21, 22, 25, 26, 32, 33, 71, 72, 74, 75	0.0V	<b>Digital Ground.</b> Ground connections. These pins should be connected to the system analog ground plane.
<b>No Connect</b>			
N/C	1, 8, 10, 23, 24, 31, 46, 57, 59, 73	open	<b>Not Connected.</b>

### Notes:

1. Absolute maximum ratings are limiting values applied individually while all other parameters are within specified operating conditions. Functional operation under any of these conditions is NOT implied. Performance and reliability are guaranteed only if Operating Conditions are not exceeded.
2. Applied voltage must be current limited to specified range.
3. Forcing voltage must be limited to specified range.
4. Current is specified as conventional current flowing into the device.

### Notes:

1. Bandwidth is the frequency up to which a full-scale sinewave can be digitized without spurious codes.
2. Values shown in Typ. column are typical for V<sub>DD</sub> = V<sub>DDA</sub> = +5V and T<sub>A</sub> = 25°C.
3. SNR values do not include the harmonics of the fundamental frequency.
4. SFDR is the ratio in dB of fundamental amplitude to the harmonic with the highest amplitude.
5. Characteristics specified for V<sub>RT</sub> = 2.6V, V<sub>RB</sub> = 0.6V.

## Application Notes

The circuit in Figure 10 employs a band-gap reference to generate a variable  $R_{TX}$  reference voltages for the TMC1103 as well as a bias voltage to offset the wideband input amplifiers to mid-range. The operational amplifier in the reference circuitry is a standard 741-type.

The voltage reference at  $R_{TX}$  can be adjusted from 0.0 to 2.4 volts while  $R_{BX}$  is grounded. Schottky diodes can be used at  $V_{INX}$  to restrict the wideband amplifier output to between  $-0.3V$  and  $V_{DD} + 0.3V$ . Diode protection is good practice to limit the analog input voltage at  $V_{INX}$  to the safe operating range.

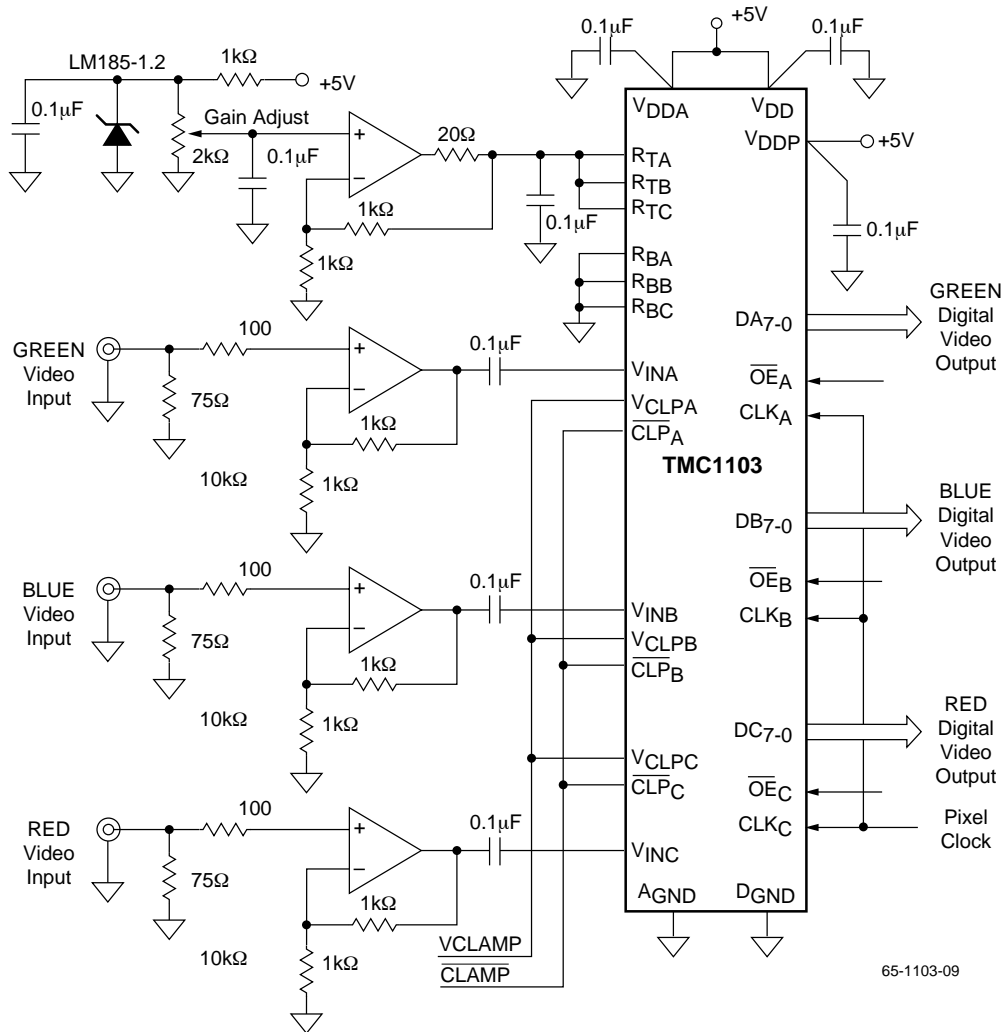

Figure 10. Typical Interface Circuit – High Performance

### Grounding

The TMC1103 has separate analog and digital circuits. To keep digital system noise from the A/D converter, it is recommended that power supply voltages ( $V_{DD}$  and  $V_{DDA}$ ) come from the same source, and that ground connections ( $DGND$  and  $AGND$ ) be made to the analog ground plane, and as close as possible to the device pins. Power supply pins should be individually decoupled at the pin. The digital circuitry that gets its input from the TMC1103 should be referred to the system digital ground plane.

### Printed Circuit Board Layout

Designing with high performance mixed-signal circuits demands printed circuits with ground planes. Overall system performance is strongly influenced by the board layout. Capacitive coupling from digital to analog circuits may result in poor A/D conversion. Consider the following suggestions when doing the layout:

1. Keep the critical analog traces ( $V_N$ ,  $R_{TX}$ ,  $R_{BX}$ ) as short as possible and as far as possible from all digital signals. The TMC1103 should be located close to the analog input connectors.

## 2. Segregate traces:

- A/D analog
- D/A analog
- Clocks
- Digital

Treat analog inputs as transmission lines. Cleanly route traces over the ground plane bearing in mind that the return currents will flow through the ground plane beneath the traces. Do not route digital traces nearby. A few inches of digital trace less than a few line widths from an analog trace will cross-couple noise into adjacent analog circuits.

3. The power plane for the TMC1103 should be separate from that which supplies the rest of the digital circuitry. A single power plane should be used for all of the VDD pins. If the power supply for the TMC1103 is the same as that of the system's digital circuitry, power to the TMC1103 should be decoupled with ferrite beads and 0.1 $\mu$ F capacitors to reduce noise.
4. The ground plane should be solid, not cross-hatched. Connections to the ground plane should have very short leads.

5. Decoupling capacitors should be applied liberally to VDD pins. Remember that not all power supply pins are created equal. They supply different circuits on the integrated circuit, each of which generate varying amounts and types of noise. For best results, use 0.1 $\mu$ F ceramic capacitors. Lead lengths should be minimized.
6. CLK<sub>X</sub> should be handled carefully. Jitter and noise on this clock may degrade performance. Terminate the clock line, if needed, to eliminate overshoot and ringing.

### LIFE SUPPORT POLICY

FAIRCHILD'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF FAIRCHILD SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user.
2. A critical component in any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
