

# OCTAL SIMULTANEOUS-SAMPLING 24-BIT ANALOG-TO-DIGITAL CONVERTER

Check for Samples: ADS1278-HT

# **FEATURES**

- Simultaneously Measure Eight Channels
- Up to 128-kSPS Data Rate
- AC Performance: 62-kHz Bandwidth 111-dB SNR (High-Resolution Mode) –108-dB THD
- DC Accuracy: 0.8-µV/°C Offset Drift 1.3-ppm/°C Gain Drift
- Selectable Operating Modes: High-Speed: 128 kSPS, 106 dB SNR High-Resolution: 52 kSPS, 111 dB SNR Low-Power: 52 kSPS, 31 mW/ch Low-Speed: 10 kSPS, 7 mW/ch
- Linear Phase Digital Filter
- SPI™ or Frame-Sync Serial Interface
- Low Sampling Aperture Error
- Modulator Output Option (digital filter bypass)
- Analog Supply: 5 V
- Digital Core: 1.8 V
- I/O Supply: 1.8 V to 3.3 V
- Currently Available in an HTQFP-64 PowerPAD<sup>™</sup> package, an 84-Pin HFQ Package and a KGD Chiptray Option

# SUPPORTS EXTREME TEMPERATURE APPLICATIONS

- Controlled Baseline
- One Assembly/Test Site
- One Fabrication Site
- Available in Extreme (-55°C/210°C) Temperature Range <sup>(1)</sup>
- Extended Product Life Cycle
- Extended Product-Change Notification
- Product Traceability
- Texas Instruments High Temperature Products Utilize Highly Optimized Silicon (Die) Solutions With Dsign and Process Enhancements to Maximize Performance Over Extended Temperatures

### **APPLICATIONS**

- Down-Hole Drilling
- High Temperature Environments
- Vibration/Modal Analysis
- Multi-Channel Data Acquisition
- Acoustics/Dynamic Strain Gauges
- Pressure Sensors

### DESCRIPTION

Based on the single-channel ADS1271, the ADS1278 (octal) is a 24-bit, delta-sigma ( $\Delta\Sigma$ ) analog-to-digital converter (ADC) with data rates up to 128 k samples per second (SPS), allowing simultaneous sampling of eight channels.

Traditionally, industrial delta-sigma ADCs offering good drift performance use digital filters with large passband droop. As a result, they have limited signal bandwidth and are mostly suited for dc measurements. High-resolution ADCs in audio applications offer larger usable bandwidths, but the offset and drift specifications are significantly weaker than respective industrial counterparts. The ADS1278 combines these types of converters, allowing highprecision industrial measurement with excellent dc and ac specifications.

The high-order, chopper-stabilized modulator achieves very low drift with low in-band noise. The onboard decimation filter suppresses modulator and signal out-of-band noise. These ADCs provide a usable signal bandwidth up to 90% of the Nyquist rate with less than 0.005 dB of ripple.

Four operating modes allow for optimization of speed, resolution, and power. All operations are controlled directly by pins; there are no registers to program. The device is fully specified over the extended industrial range (-55°C to 210°C) and is available in an HTQFP-64 PowerPAD package (-55°C to 175°C), an 84-pin HFQ package and a KGD chiptray option.

#### SBAS447E - MARCH 2009-REVISED APRIL 2013

ADS1278

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, SPRA953.
 The junction-to-ambient thermal resistance under natural convection is obtained in a simulation on a JEDEC-standard, high-K board, as

2) The junction-to-ambient thermal resistance under natural convection is obtained in a simulation on a JEDEC-standard, high-K board, as specified in JESD51-7, in an environment described in JESD51-2a.

(3) The junction-to-case (top) thermal resistance is obtained by simulating a cold plate test on the package top. No specific JEDECstandard test exists, but a close description can be found in the ANSI SEMI standard G30-88.

(4) The junction-to-board thermal resistance is obtained by simulating in an environment with a ring cold plate fixture to control the PCB temperature, as described in JESD51-8.

(5) The junction-to-top characterization parameter,  $\psi_{JT}$ , estimates the junction temperature of a device in a real system and is extracted from the simulation data for obtaining  $\theta_{JA}$ , using a procedure described in JESD51-2a (sections 6 and 7).

(6) The junction-to-board characterization parameter,  $\psi_{JB}$ , estimates the junction temperature of a device in a real system and is extracted from the simulation data for obtaining  $\theta_{JA}$ , using a procedure described in JESD51-2a (sections 6 and 7).

(7) The junction-to-case (bottom) thermal resistance is obtained by simulating a cold plate test on the exposed (power) pad. No specific JEDEC standard test exists, but a close description can be found in the ANSI SEMI standard G30-88.

(1) Minimum and maximum parameters are characterized for operation at  $T_A = 175^{\circ}C$  but may not be production tested at that temperature. Production test limits with statistical guardbands are used to ensure high temperature performance.

(2)  $FSR = full-scale range = 2V_{REF}$ .

(3)  $f_{CLK} = 32.768MHz$  max for High-Speed mode, and 27MHz max for all other modes. When  $f_{CLK} > 27MHz$ , operation is limited to Frame-Sync mode and  $V_{REF} \le 2.6V$ .

(4) SPS = samples per second.

(5) Best fit method.

- (6) Worst-case channel crosstalk between one or more channels.
- (7) Minimum SNR is ensured by the limit of the DC noise specification.
- (8) THD includes the first nine harmonics of the input signal; Low-Speed mode includes the first five harmonics.

(1) FSR = full-scale range = 2V<sub>REF</sub>.
 (2) f<sub>CLK</sub> = 32.768MHz max for High-Speed mode, and 27MHz max for all other modes. When f<sub>CLK</sub> > 27MHz, operation is limited to Frame-Sync mode and V<sub>REF</sub> ≤ 2.6V.
 (3) SPS = samples per second.

(4) Best fit method.

- Worst-case channel crosstalk between one or more channels. (5)
- (6) Minimum SNR is ensured by the limit of the DC noise specification.
- THD includes the first nine harmonics of the input signal; Low-Speed mode includes the first five harmonics. (7)

| t <sub>DOHD</sub> <sup>(4)</sup> <sup>(6)</sup> | SCLK falling edge to new DOUT invalid (hold time)                  | 10  |     |        | ns               |
| t <sub>DOPD</sub> <sup>(4)</sup>                | SCLK falling edge to new DOUT valid (propagation delay)            |     |     | 32     | ns               |
| t <sub>DIST</sub>                               | New DIN valid to falling edge of SCLK (setup time)                 | 6   |     |        | ns               |
| t <sub>DIHD</sub> <sup>(6)</sup>                | Old DIN valid to falling edge of SCLK (hold time)                  | 6   |     |        | ns               |

Timing parameters are characerized or guranteed by design for specified temperature but not production tested. (1)

(2)

 $f_{CLK} = 27$ MHz maximum. Depends on MODE[1:0] and CLKDIV selection. See Table 10 ( $f_{CLK}/f_{DATA}$ ). (3)

Load on  $\overline{DRDY}$  and  $\overline{DOUT} = 20$ pF.

(4) (5)

For best performance, limit  $f_{SCLK}/f_{CLK}$  to ratios of 1, 1/2, 1/4, 1/8, etc.  $t_{DOHD}$  (DOUT hold time) and  $t_{DIHD}$  (DIN hold time) are specified under opposite worst-case conditions (digital supply voltage and ambient temperature). Under equal conditions, with DOUT connected directly to DIN, the timing margin is >4ns. (6)

#### Figure 1. TIMING CHARACTERISTICS: FRAME-SYNC FORMAT

# TIMING REQUIREMENTS: FRAME-SYNC FORMAT<sup>(1)</sup>

For  $T_A = -40^{\circ}$ C to  $125^{\circ}$ C, IOVDD = 1.65 V to 3.6 V, and DVDD = 1.65 V to 1.95 V.

(2)

(3)

Timing parameters are characerized or guranteed by design for specified temperature but not production tested. Depends on MODE[1:0] and CLKDIV selection. See Table 10 ( $f_{CLK}/f_{DATA}$ ). SCLK must be continuously running and limited to ratios of 1, 1/2, 1/4, and 1/8 of  $f_{CLK}$ .  $t_{DOHD}$  (DOUT hold time) and  $t_{DIHD}$  (DIN hold time) are specified under opposite worst-case conditions (digital supply voltage and (4)

ambient temperature). Under equal conditions, with DOUT connected directly to DIN, the timing margin is >4 ns.

(5) Load on DOUT = 20 pF.

#### OVERVIEW

The ADS1278 is an octal 24-bit, delta-sigma ADC based on the single-channel ADS1271. It offers the combination of outstanding dc accuracy and superior ac performance. Figure 54 shows the block diagram. The converter is comprised of eight advanced, 6th-order, chopper-stabilized, delta-sigma modulators followed by low-ripple, linear phase FIR filters. The modulators measure the differential input signal,  $V_{IN} = (AINP - AINN)$ , against the differential reference,  $V_{REF} = (VREFP - VREFN)$ . The digital filters receive the modulator signal and provide a low-noise digital output. To allow tradeoffs among speed, resolution, and power, four operating modes are supported:

High-Speed, High-Resolution, Low-Power, and Low-Speed. Table 5 summarizes the performance of each mode.

In High-Speed mode, the maximum data rate is 128 kSPS (when operating at 128 kSPS, Frame-Sync format must be used). In High-Resolution mode, the SNR = 111dB ( $V_{REF}$  = 3.0 V); in Low-Power mode, the power dissipation is 31 mW/channel; and in Low-Speed mode, the power dissipation is only 7 mW/channel at 10.5 kSPS. The digital filters can be bypassed, enabling direct access to the modulator output.

The ADS1278 is configured by simply setting the appropriate I/O pins—there are no registers to program. Data are retrieved over a serial interface that supports both SPI and Frame-Sync formats. The ADS1278 has a daisy-chainable output and the ability to synchronize externally, so it can be used conveniently in systems requiring more than eight channels.

Figure 54. Block Diagram

#### FUNCTIONAL DESCRIPTION

The ADS1278 is a delta-sigma ADC consisting of eight independent converters that digitize eight input signals in parallel.

The converter is composed of two main functional blocks to perform the ADC conversions: the modulator and the digital filter. The modulator samples the input signal together with sampling the reference voltage to produce a 1s density output stream. The density of the output stream is proportional to the analog input level relative to the reference voltage. The pulse stream is filtered by the internal digital filter where the output conversion result is produced.

In operation, the input signal is sampled by the modulator at a high rate (typically 64x higher than the final output data rate). The quantization noise of the modulator is moved to a higher frequency range where the internal digital filter removes it. Oversampling results in very low levels of noise within the signal passband.

Since the input signal is sampled at a very high rate, input signal aliasing does not occur until the input signal frequency is at the modulator sampling rate. This architecture greatly relaxes the requirement of external antialiasing filters because of the high modulator sampling rate.

#### SAMPLING APERTURE MATCHING

The ADS1278 converter operates from the same CLK input. The CLK input controls the timing of the modulator sampling instant. The converter is designed such that the sampling skew, or modulator sampling aperture match between channels, is controlled. Furthermore, the digital filters are synchronized to start the convolution phase at the same modulator clock cycle. This design results in excellent phase match among the ADS1278 channels.

Figure 37 shows the inter-device channel sample matching for the ADS1278.

#### FREQUENCY RESPONSE

The digital filter sets the overall frequency response. The filter uses a multi-stage FIR topology to provide linear phase with minimal passband ripple and high stop band attenuation. The filter coefficients are identical to the coefficients used in the ADS1271. The oversampling ratio of the digital filter (that is, the ratio of the modulator sampling to the output data rate, or  $f_{MOD}/f_{DATA}$ ) is a function of the selected mode, as shown in Table 6.

#### Table 6. Oversampling Ratio versus Mode

| MODE SELECTION  | OVERSAMPLING RATIO (f <sub>MOD</sub> /f <sub>DATA</sub> ) |
|-----------------|---|
| High-Speed      | 64  |
| High-Resolution | 128   |
| Low-Power       | 64  |
| Low-Speed       | 64  |

#### High-Speed, Low-Power, and Low-Speed Modes

The digital filter configuration is the same in High-Speed, Low-Power, and Low-Speed modes with the oversampling ratio set to 64. Figure 55 shows the frequency response in High-Speed, Low-Power, and Low-Speed modes normalized to  $f_{DATA}$ . Figure 56 shows the passband ripple. The transition from passband to stop band is shown in Figure 57. The overall frequency response repeats at 64x multiples of the modulator frequency  $f_{MOD}$ , as shown in Figure 58.

Figure 55. Frequency Response for High-Speed, Low-Power, and Low-Speed Modes

Figure 56. Passband Response for High-Speed, Low-Power, and Low-Speed Modes

Figure 57. Transition Band Response for High-Speed, Low-Power, and Low-Speed Modes

Figure 58. Frequency Response Out to  $f_{\text{MOD}}$  for High-Speed, Low-Power, and Low-Speed Modes

These image frequencies, if present in the signal and not externally filtered, will fold back (or alias) into the passband, causing errors. The stop band of the ADS1278 provides 100 dB attenuation of frequencies that begin just beyond the passband and continue out to  $f_{MOD}$ . Placing an antialiasing, low-pass filter in front of the ADS1278 inputs is recommended to limit possible high-amplitude, out-of-band signals and noise. Often, a simple RC filter is sufficient. Table 7 lists the image rejection versus external filter order.

#### Table 7. Antialiasing Filter Order Image Rejection

| ANTIALIASING |            | ECTION (dB)<br>t f <sub>DATA</sub> ) |
|--------------|------------|--------------------------------------|
| FILTER ORDER | HS, LP, LS | HR                                   |
| 1            | 39         | 45                                   |
| 2            | 75         | 87                                   |
| 3            | 111        | 129                                  |

#### **High-Resolution Mode**

The oversampling ratio is 128 in High-Resolution mode. Figure 59 shows the frequency response in High-Resolution mode normalized to  $f_{DATA}$ . Figure 60 shows the passband ripple, and the transition from passband to stop band is shown in Figure 61. The overall frequency response repeats at multiples of the modulator frequency  $f_{MOD}$  (128 ×  $f_{DATA}$ ), as shown in Figure 62. The stop band of the ADS1278 provides 100 dB attenuation of frequencies that begin just beyond the passband and continue out to  $f_{MOD}$ . Placing an antialiasing, low-pass filter in front of the ADS1278 inputs is recommended to limit possible high-amplitude out-of-band signals and noise. Often, a simple RC filter is sufficient. Table 7 lists the image rejection versus external filter order.

Figure 59. Frequency Response for High-Resolution Mode

Figure 60. Passband Response for High-Resolution Mode

www.ti.com

Figure 61. Transition Band Response for High-Resolution mode

Figure 62. Frequency Response Out to  $f_{\text{MOD}}$  for High-Resolution Mode

#### PHASE RESPONSE

The ADS1278 incorporates a multiple stage, linear phase digital filter. Linear phase filters exhibit constant delay time versus input frequency (constant group delay). This characteristic means the time delay from any instant of the input signal to the same instant of the output data is constant and is independent of input signal frequency. This behavior results in essentially zero phase errors when analyzing multi-tone signals.

#### SETTLING TIME

As with frequency and phase response, the digital filter also determines settling time. Figure 63 shows the output settling behavior after a step change on the analog inputs normalized to conversion periods. The X-axis is given in units of conversion. Note that after the step change on the input occurs, the output data change very little prior to 30 conversion periods. The output data are fully settled after 76 conversion periods for High-Speed and Low-Power modes, and 78 conversion periods for High-Resolution mode.

Figure 63. Step Response

#### DATA FORMAT

The ADS1278 outputs 24 bits of data in twos complement format.

A positive full-scale input produces an ideal output code of 7FFFFFh, and the negative full-scale input produces an ideal output code of 800000h. The output clips at these codes for signals exceeding fullscale. Table 8 summarizes the ideal output codes for different input signals.

| Table 8. Ideal | <b>Output Code</b> | versus | Input Signal |  |
|----------------|--------------------|--------|--------------|--|

SBAS447E - MARCH 2009 - REVISED APRIL 2013

| INPUT SIGNAL V <sub>IN</sub><br>(AINP – AINN)       | IDEAL OUTPUT CODE <sup>(1)</sup> |  |  |
|---|----------------------------------|--|--|
| ≥ +V <sub>REF</sub>                                 | 7FFFFh                           |  |  |
| $\frac{+V_{\text{REF}}}{2^{23}-1}$                  | 000001h                          |  |  |
| 0   | 000000h                          |  |  |
| $\frac{-V_{REF}}{2^{23}-1}$                         | FFFFFh                           |  |  |
| $\leq -V_{REF}\left(\frac{2^{23}}{2^{23}-1}\right)$ | 800000h                          |  |  |

(1) Excludes effects of noise, INL, offset, and gain errors.

#### ANALOG INPUTS (AINP, AINN)

The ADS1278 measures each differential input signal  $V_{IN} = (AINP - AINN)$  against the common differential reference  $V_{REF} = (VREFP - VREFN)$ . The most positive measurable differential input is  $+V_{REF}$ , which produces the most positive digital output code of 7FFFFh. Likewise, the most negative measurable differential input is  $-V_{REF}$ , which produces the most negative digital output code of 800000h.

For optimum performance, the inputs of the ADS1278 are intended to be driven differentially. For singleended applications, one of the inputs (AINP or AINN) can be driven while the other input is fixed (typically to AGND or 2.5 V). Fixing the input to 2.5 V permits bipolar operation, thereby allowing full use of the entire converter range.

While the ADS1278 measures the differential input signal, the absolute input voltage is also important. This value is the voltage on either input (AINP or AINN) with respect to AGND. The range for this voltage is:

-0.1 V < (AINN or AINP) < AVDD + 0.1 V

If either input is taken below -0.4 V or above (AVDD + 0.4 V), ESD protection diodes on the inputs may turn on. If these conditions are possible, external Schottky clamp diodes or series resistors may be required to limit the input current to safe values (see the Absolute Maximum Ratings table).

The ADS1278 is a very high-performance ADC. For optimum performance, it is critical that the appropriate circuitry be used to drive the ADS1278 inputs. See the *Application Information* section for several recommended circuits.

The ADS1278 uses switched-capacitor circuitry to measure the input voltage. Internal capacitors are charged by the inputs and then discharged. Figure 64 shows a conceptual diagram of these circuits. Switch S<sub>2</sub> represents the net effect of the modulator circuitry in discharging the sampling capacitor; the actual implementation is different. The timing for switches S<sub>1</sub> and S<sub>2</sub> is shown in Figure 65. The sampling time ( $t_{SAMPLE}$ ) is the inverse of modulator sampling frequency ( $f_{MOD}$ ) and is a function of the mode, the CLKDIV input, and CLK frequency, as shown in Table 9.

Figure 64. Equivalent Analog Input Circuitry

Figure 65. S<sub>1</sub> and S<sub>2</sub> Switch Timing for Figure 64

| Table 9. Modulator Frequency (f <sub>MOD</sub> ) Mode        Selection |  |
|--|--|
|--|--|

| MODE SELECTION  | CLKDIV | f <sub>MOD</sub>     |
|-----------------|--------|----------------------|
| High-Speed      | 1      | f <sub>CLK</sub> /4  |
| High-Resolution | 1      | f <sub>CLK</sub> /4  |
| Law Dawar       | 1      | f <sub>CLK</sub> /8  |
| Low-Power       | 0      | f <sub>CLK</sub> /4  |
| Law Grand       | 1      | f <sub>CLK</sub> /40 |
| Low-Speed       | 0      | f <sub>CLK</sub> /8  |

The average load presented by the switched capacitor input can be modeled with an effective differential impedance, as shown in Figure 66. Note that the effective impedance is a function of  $f_{MOD}$ .

www.ti.com

Figure 66. Effective Input Impedances

#### VOLTAGE REFERENCE INPUTS (VREFP, VREFN)

The voltage reference for the ADS1278 ADC is the differential voltage between VREFP and VREFN:  $V_{RFF} = (VREFP - VREFN)$ . The voltage reference is common to all channels. The reference inputs use a structure similar to that of the analog inputs with the equivalent circuitry on the reference inputs shown in Figure 67. As with the analog inputs, the load presented by the switched capacitor can be modeled with an effective impedance, as shown in Figure 68. However, the reference input impedance depends on the number of active (enabled) channels in addition to f<sub>MOD</sub>. As a result of the change of reference input impedance caused by enabling and disabling channels, the regulation and setting time of the external reference should be noted, so as not to affect the readings.

Figure 68. Effective Reference Impedance

ESD diodes protect the reference inputs. To keep these diodes from turning on, make sure the voltages on the reference pins do not go below AGND by more than 0.4 V, and likewise do not exceed AVDD by 0.4 V. If these conditions are possible, external Schottky clamp diodes or series resistors may be required to limit the input current to safe values (see the Absolute Maximum Ratings table).

Note that the valid operating range of the reference inputs is limited to the following parameters:

 $-0.1 \text{ V} \leq \text{VREFN} \leq +0.1 \text{ V}$ 

 $VREFN + 0.5 V \le VREFP \le AVDD + 0.1 V$ 

#### CLOCK INPUT (CLK)

The ADS1278 requires a clock input for operation. The individual converters of the ADS1278 operate from the same clock input. At the maximum data rate, the clock input can be either 27 MHz or 13.5 MHz for Low-Power mode, or 2 7MHz or 5.4 MHz for Low-Speed mode, determined by the setting of the CLKDIV input. For High-Speed mode, the maximum CLK input frequency is 32.768 MHz. For High-Resolution mode, the maximum CLK input frequency is 27 MHz. The selection of the external clock frequency (f<sub>CLK</sub>) does not affect the resolution of the ADS1278. Use of a slower f<sub>CLK</sub> can reduce the power consumption of an external clock buffer. The output data rate scales with clock frequency, down to a minimum clock frequency of  $f_{CLK} = 100$  kHz. Table 10 summarizes the ratio of the clock input frequency (f<sub>CLK</sub>) to data rate (f<sub>DATA</sub>), maximum data rate and corresponding maximum clock input for the four operating modes.

As with any high-speed data converter, a high-quality, low-jitter clock is essential for optimum performance. Crystal clock oscillators are the recommended clock source. Make sure to avoid excess ringing on the clock input; keeping the clock trace as short as possible, and using a  $50-\Omega$  series resistor placed close to the source end, often helps.

| Low Crood         | 27                            | 1      | 2,560                               | 10 5 47            |
| Low-Speed         | 5.4                           | 0      | 512                                 | 10,547             |

#### MODE SELECTION (MODE)

The ADS1278 supports four modes of operation: High-Speed, High-Resolution, Low-Power, and Low-Speed. The modes offer optimization of speed, resolution, and power. Mode selection is determined by the status of the digital input MODE[1:0] pins, as shown in Table 11. The ADS1278 continually monitors the status of the MODE pin during operation.

**Table 11. Mode Selection** 

| MODE[1:0] | MODE SELECTION  | MAX f <sub>DATA</sub> <sup>(1)</sup> |
|-----------|-----------------|--------------------------------------|
| 00        | High-Speed      | 128,000                              |
| 01        | High-Resolution | 52,734                               |
| 10        | Low-Power       | 52,734                               |
| 11        | Low-Speed       | 10,547                               |

(1) f<sub>CLK</sub> = 27 MHz max (32.768MHz max in High-Speed mode).

When using the SPI protocol, DRDY is held high after a mode change occurs until settled (or valid) data are ready; see Figure 69 and Table 12.

In Frame-Sync protocol, the DOUT pins are held low after a mode change occurs until settled data are ready; see Figure 69 and Table 12. Data can be read from the device to detect when DOUT changes to logic 1, indicating that the data are valid.

| t <sub>NDR-FS</sub>  | Time for new data to be ready (Frame-Sync) | 127 |     | 128 | Conversions (1/f <sub>DATA</sub> ) |

#### SYNCHRONIZATION (SYNC)

<u>The ADS1278</u> can be synchronized by pulsing the SYNC pin low and then returning the pin high. When the pin goes low, the conversion process stops, and the internal counters used by the digital filter are reset. When the SYNC pin returns high, the conversion process restarts. Synchronization allows the conversion to be aligned with an external event, such as the changing of an external multiplexer on the analog inputs, or by a reference timing pulse.

Because the ADS1278 converters operate in <u>parallel</u> from the same master clock and use the same SYNC input control, they are always in synchronization with each other. The aperture match among internal channels is typically less than 500 ps. However, the synchronization of multiple devices is somewhat different. At device power-on, variations in internal reset thresholds from device to device may result in uncertainty in conversion timing.

The SYNC pin can be used to synchronize multiple devices to within the same CLK cycle. Figure 70 illustrates the timing requirement of SYNC and CLK in SPI format.

See Figure 71 for the Frame-Sync format timing requirement.

After synchronization, indication of valid data depends on whether SPI or Frame-Sync format was used.

In the SPI format, DRDY goes high as soon as SYNC is taken low; see Figure 70. After SYNC is returned high, DRDY stays high while the digital filter is settling. Once valid data are ready for retrieval, DRDY goes low.

In the Frame-Sync format, DOUT goes low as soon as SYNC is taken low; see Figure 71. After SYNC is returned high, DOUT stays low while the digital filter is settling. Once valid data are ready for retrieval, DOUT begins to output valid data. For proper synchronization, FSYNC, <u>SCLK</u>, and CLK must be established before taking SYNC high, and must then remain running. If the clock inputs (CLK, FSYNC or SCLK) are subsequently interrupted or reset, reassert the SYNC pin.

For consistent performance, re-assert SYNC after device power-on when data first appear.

SBAS447E - MARCH 2009-REVISED APRIL 2013

#### POWER-DOWN (PWDN)

The channels of the ADS1278 can be independently powered down by use of the PWDN inputs. To enter the power-down mode, hold the respective PWDN pin low for at least two CLK cycles. To exit power-down, return the corresponding PWDN pin high. Note that when all channels are powered down, the ADS1278 enters a microwatt ( $\mu$ W) power state where all internal biasing is disabled. In this state, the TEST[1:0] input pins must be driven; all other input pins can float. The ADS1278 outputs remain driven.

As shown in Figure 72 and Table 15, a maximum of 130 conversion cycles must elapse for SPI interface, and 129 conversion cycles must elapse for Frame-Sync, before reading data after exiting power-down. Data from channels already running are not affected. The user software can perform the required delay time in any of the following ways:

- 1. Count the number of data conversions after taking the PWDN pin high.
- <u>Delay</u> 129/f<sub>DATA</sub> or 130/f<sub>DATA</sub> after taking the PWDN pins high, then read data.

3. Detect for non-zero data in the powered-up channel.

After powering up one or more channels, the channels are synchronized to each other. It is not necessary to use the SYNC pin to synchronize them.

When a channel is powered down in TDM data format, the data for that channel are either forced to zero (fixed-position TDM data mode) or replaced by shifting the data from the next channel into the vacated data position (dynamic-position TDM data mode).

In Discrete data format, the data are always forced to zero. When powering-up a channel in dynamicposition TDM data format mode, the channel data remain packed until the data are ready, at which time the data frame is expanded to include the justpowered channel data. See the *Data Format* section for details.

Figure 72. Power-Down Timing

#### FORMAT[2:0]

Data can be read from the ADS1278 with two interface protocols (SPI or Frame-Sync) and several options of data formats (TDM/Discrete and Fixed/Dynamic data positions). The FORMAT[2:0] inputs are used to select among the options. Table 16 lists the available options. See the *DOUT Modes* section for details of the DOUT Mode and Data Position.

| FORMAT[2:0] | INTERFACE<br>PROTOCOL | DOUT<br>MODE | DATA<br>POSITION |
|-------------|-----------------------|--------------|------------------|
| 000         | SPI                   | TDM          | Dynamic          |
| 001         | SPI                   | TDM          | Fixed            |
| 010         | SPI                   | Discrete     | —                |

| 100         | Frame-Sync            | TDM          | Fixed            |
| 101         | Frame-Sync            | Discrete     | —                |
| 110         | Modulator Mode        | —            | —                |

Table 16. Data Output Format

#### SERIAL INTERFACE PROTOCOLS

Data are retrieved from the ADS1278 using the serial interface. Two protocols are available: SPI and Frame-Sync. The <u>same</u> pins are used for both interfaces: SCLK, DRDY/FSYNC, DOUT[8:1], and DIN. The FORMAT[2:0] pins select the desired interface protocol.

#### SPI SERIAL INTERFACE

The SPI-compatible format is a read-only interface. <u>Data ready</u> for retrieval are indicated by the falling DRDY output and are shifted out on the falling edge of SCLK, MSB first. The interface can be daisychained using the DIN input when using multiple devices. See the *Daisy-Chaining* section for more information.

NOTE: The SPI format is limited to a CLK input frequency of 27 MHz, maximum. For CLK input operation above 27 MHz (High-Speed mode only), use Frame-Sync format.

#### SCLK

The serial clock (SCLK) features a Schmitt-triggered input and shifts out data on DOUT on the falling edge. It also shifts in data on the falling edge on DIN when this pin is being used for daisy-chaining. The device shifts data out on the falling edge and the user normally shifts this data in on the rising edge. Even though the SCLK input has hysteresis, it is recommended to keep SCLK as clean as possible to prevent glitches from accidentally shifting the data.

SBAS447E - MARCH 2009-REVISED APRIL 2013

SCLK may be run as fast as the CLK frequency. SCLK may be either in free-running or stop-clock operation between conversions. Note that one  $f_{CLK}$  is required after the falling edge of DRDY until the first rising edge of SCLK. For best performance, limit  $f_{SCLK}/f_{CLK}$  to ratios of 1, 1/2, 1/4, 1/8, etc. When the device is configured for modulator output, SCLK becomes the modulator clock output (see the *Modulator Output* section).

#### **DRDY/FSYNC (SPI Format)**

In the SPI format, this pin functions as the DRDY output. It goes low when data are ready for retrieval and then returns high on the falling edge of the first subsequent SCLK. If data are not retrieved (that is, SCLK is held low), DRDY pulses high just before the next conversion data are ready, as shown in Figure 73. The new data are loaded within one CLK cycle before DRDY goes low. All data must be shifted out before this time to avoid being overwritten.

Figure 73. DRDY Timing with No Readback

#### DOUT

The conversion data are output on DOUT[8:1]. The MSB data are valid on DOUT[8:1] after DRDY goes low. Subsequent bits are shifted out with each falling edge of SCLK. If daisy-chaining, the data shifted in using DIN appear on DOUT after all channel data have been shifted out. When the device is configured for modulator output, DOUT[8:1] becomes the modulator data output for each channel (see the *Modulator Output* section).

#### DIN

This input is used when multiple ADS1278s are to be daisy-chained together. The DOUT1 pin of the first device connects to the DIN pin of the next, etc. It can be used with either the SPI or Frame-Sync formats. Data are shifted in on the falling edge of SCLK. When using only one ADS1278, tie DIN low. See the *Daisy-Chaining* section for more information.

#### SBAS447E - MARCH 2009 - REVISED APRIL 2013

#### FRAME-SYNC SERIAL INTERFACE

Frame-Sync format is similar to the interface often used on audio ADCs. It operates in slave fashion—the user must supply framing signal FSYNC (similar to the *left/right clock* on stereo audio ADCs) and the serial clock SCLK (similar to the *bit clock* on audio ADCs). The data are output MSB first or *leftjustified* on the rising edge of FSYNC. When using Frame-Sync format, the FSYNC and SCLK inputs must be continuously running with the relationships shown in the Frame-Sync Timing Requirements.

#### SCLK

The serial clock (SCLK) features a Schmitt-triggered input and shifts out data on DOUT on the falling edge. It also shifts in data on the falling edge on DIN when this pin is being used for daisy-chaining. Even though SCLK has hysteresis, it is recommended to keep SCLK as clean as possible to prevent glitches from accidentally shifting the data. When using Frame-Sync format, SCLK must run continuously. If it is shut down, the data readback will be corrupted. The number of SCLKs within a frame period (FSYNC clock) can be any power-of-2 ratio of CLK cycles (1, 1/2, 1/4, etc), as long as the number of cycles is sufficient to shift the data output from all channels within one frame. When the device is configured for modulator output, SCLK becomes the modulator clock output (see the Modulator Output section).

#### **DRDY/FSYNC** (Frame-Sync Format)

In Frame-Sync format, this pin is used as the FSYNC input. The frame-sync input (FSYNC) sets the frame period, which must be the same as the data rate. The required number of  $f_{CLK}$  cycles to each FSYNC period depends on the mode selection and the CLKDIV input. Table 10 indicates the number of CLK cycles to each frame ( $f_{CLK}/f_{DATA}$ ). If the FSYNC period is not the proper value, data readback will be corrupted.

#### DOUT

The conversion data are shifted out on DOUT[8:1]. The MSB data become valid on DOUT[8:1] after FSYNC goes high. The subsequent bits are shifted out with each falling edge of SCLK. If daisy-chaining, the data shifted in using DIN appear on DOUT[8:1] after all channel data have been shifted out. When the device is configured for modulator output, DOUT becomes the modulator data output (see the *Modulator Output* section).

#### DIN

This input is used when multiple ADS1278s are to be daisy-chained together. It can be used with either SPI or Frame-Sync formats. Data are shifted in on the falling edge of SCLK. When using only one ADS1278, tie DIN low. See the *Daisy-Chaining* section for more information.

#### DOUT MODES

For both SPI and Frame-Sync interface protocols, the data are shifted out either through individual channel DOUT pins, in a parallel data format (Discrete mode), or the data for all channels are shifted out, in a serial format, through a common pin, DOUT1 (TDM mode).

#### **TDM Mode**

In TDM (time-division multiplexed) data output mode, the data for all channels are shifted out, in sequence, on a single pin (DOUT1). As shown in Figure 74, the data from channel 1 are shifted out first, followed by channel 2 data, etc. After the data from the last channel are shifted out, the data from the DIN input follow. The DIN is used to daisy-chain the data output from an additional ADS1278 or other compatible device. Note that when all channels of the ADS1278 are disabled, the interface is disabled, rendering the DIN input disabled as well. When one or more channels of the device are powered down, the data format of the TDM mode can be fixed or dynamic.

Figure 74. TDM Mode (All Channels Enabled)

#### **TDM Mode, Fixed-Position Data**

In this TDM data output mode, the data position of the channels remain fixed, regardless of whether the channels are powered down. If a channel is powered down, the data are forced to zero but occupy the same position within the data stream. Figure 75 shows the data stream with channel 1 and channel 3 powered down.

#### **TDM Mode, Dynamic Position Data**

In this TDM data output mode, when a channel is powered down, the data from higher channels shift one position in the data stream to fill the vacated data slot. Figure 76 shows the data stream with channel 1 and channel 3 powered down.

SBAS447E - MARCH 2009-REVISED APRIL 2013

#### **Discrete Data Output Mode**

In Discrete data output mode, the channel data are shifted out in parallel using individual channel data output pins DOUT[8:1]. After the 24th SCLK, the channel data are forced to zero. The data are also forced to zero for powered down channels. Figure 77 shows the discrete data output format.

Figure 75. TDM Mode, Fixed-Position Data (Channels 1 and 3 Shown Powered Down)

**NSTRUMENTS** 

FXAS

SBAS447E - MARCH 2009-REVISED APRIL 2013

#### DAISY-CHAINING

Multiple ADS1278s can be daisy-chained together to output data on a single pin. The DOUT1 data output pin of one device is connected to the DIN of the next device. As shown in Figure 78, the DOUT1 pin of device 1 provides the output data to a controller, and the DIN of device 2 is grounded. Figure 79 shows the data format when reading back data.

The maximum number of channels that may be daisy-chained in this way is limited by the frequency of  $f_{SCLK}$ , the mode selection, and the CLKDIV input. The frequency of  $f_{SCLK}$  must be high enough to completely shift the data out from all channels within one  $f_{DATA}$  period. Table 17 lists the maximum number of daisy-chained channels when  $f_{SCLK} = f_{CLK}$ .

To increase the number of data channels possible in a chain, a segmented DOUT scheme may be used, producing two data streams. Figure 80 illustrates four ADS1278s, with pairs of ADS1278s daisy-chained together. The channel data of each daisy-chained pair are shifted out in parallel and received by the processor through independent data channels.

#### Table 17. Maximum Channels in a Daisy-Chain

Table 17. Maximum Channels in a Daisy-Chain (f<sub>SCLK</sub> = f<sub>CLK</sub>) (continued)

| (f <sub>SCLK</sub> = | f <sub>CLK</sub> ) |
|----------------------|--------------------|
|----------------------|--------------------|

| MODE SELECTION  | CLKDIV | MAXIMUM NUMBER<br>OF CHANNELS |
|-----------------|--------|-------------------------------|
| High-Speed      | 1      | 10                            |
| High-Resolution | 1      | 21                            |
| L Dawar         | 1      | 21                            |
| Low-Power       | 0      | 10                            |
| Low Speed       | 1      | 106                           |
| Low-Speed       | 0      | 21                            |

Whether the interface protocol is SPI or Frame-Sync, it is recommended to synchronize all devices by tying the SYNC inputs together. When synchronized in SPI protocol, it is only necessary to monitor the DRDY output of one ADS1278.

In Frame-Sync interface protocol, the data from all devices are ready after the rising edge of FSYNC.

Since DOUT1 and DIN are both shifted on the falling edge of SCLK, the propagation delay on DOUT1 creates a setup time on DIN. Minimize the skew in SCLK to avoid timing violations.

SBAS447E - MARCH 2009 - REVISED APRIL 2013

Note: The number of chained devices is limited by the SCLK rate and device mode.

#### SBAS447E - MARCH 2009 - REVISED APRIL 2013

www.ti.com

#### **POWER SUPPLIES**

The ADS1278 has three power supplies: AVDD, DVDD, and IOVDD. AVDD is the analog supply that powers the modulator, DVDD is the digital supply that powers the digital core, and IOVDD is the digital I/O power supply. The IOVDD and DVDD power supplies can be tied together if desired (1.8 V). To achieve rated performance, it is critical that the power supplies are bypassed with  $0.1-\mu$ F and  $10-\mu$ F capacitors placed as close as possible to the supply pins. A single  $10-\mu$ F ceramic capacitors.

Figure 81 shows the start-up sequence of the ADS1278. At power-on, bring up the DVDD supply first, followed by IOVDD and then AVDD. Check the power-supply sequence for proper order, including the ramp rate of each supply. DVDD and IOVDD may be sequenced at the same time if the supplies are tied together. Each supply has an internal reset circuit whose outputs are summed together to generate a global power-on reset. After the supplies have exceeded the reset thresholds,  $2^{18}\ f_{CLK}$  cycles are counted before the converter initiates the conversion process. Following the CLK cycles, the data for 129 conversions are suppressed by the ADS1278 to allow output of fully-settled data. In SPI protocol, DRDY is held high during this interval. In frame-sync protocol, DOUT is forced to zero. The power supplies should be applied before any analog or digital pin is driven. For consistent performance, assert SYNC after device power-on when data first appear.

Figure 81. Start-Up Sequence

#### MODULATOR OUTPUT

The ADS1278 incorporates a 6th-order, single-bit, chopper-stabilized modulator followed by a multistage digital filter that yields the conversion results. The data stream output of the modulator is available directly, bypassing the internal digital filter. The digital filter is disabled, reducing the DVDD current, as shown in Table 18. In this mode, an external digital filter implemented in an ASIC, FPGA, or similar device is required. To invoke the modulator output, tie FORMAT[2:0], as shown in Figure 82. DOUT[8:1] then becomes the modulator data stream outputs for each channel and SCLK becomes the modulator clock output. The DRDY/FSYNC pin becomes an unused output and can be ignored. The normal operation of the Frame-Sync and SPI interfaces is disabled, and the functionality of SCLK changes from an input to an output, as shown in Figure 82.

| MODE<br>[1:0] | CLKDIV | MODULATOR<br>CLOCK OUTPUT<br>(SCLK) | DVDD (mA) |
|---------------|--------|-------------------------------------|-----------|
| 00            | 1      | f <sub>CLK</sub> /4                 | 8         |
| 01            | 1      | f <sub>CLK</sub> /4                 | 7         |
| 10            | 1      | f <sub>CLK</sub> /8                 | 4         |
| 10            | 0      | f <sub>CLK</sub> /4                 | 4         |
| 11            | 1      | f <sub>CLK</sub> /40                | 1         |
| 11            | 0      | f <sub>CLK</sub> /8                 | 1         |

Figure 82. Modulator Output

In modulator output mode, the frequency of the modulator clock output (SCLK) depends on the mode selection of the ADS1278. Table 18 lists the modulator clock output frequency and DVDD current versus device mode.

Figure 83 shows the timing relationship of the modulator clock and data outputs.

The data output is a modulated 1s density data stream. When  $V_{IN} = +V_{REF}$ , the 1s density is approximately 80% and when  $V_{IN} = -V_{REF}$ , the 1s density is approximately 20%.

Figure 83. Modulator Output Timing

#### PIN TEST USING TEST[1:0] INPUTS

The test mode feature of the ADS1278 allows continuity testing of the digital I/O pins. In this mode, the normal functions of the digital pins are disabled and routed to each other as pairs through internal logic, as shown in Table 19. The pins in the left column drive the output pins in the right column. **Note:** some of the digital input pins become outputs; these outputs must be accommodated in the design. The analog input, power supply, and ground pins all remain connected as normal. The test mode is engaged by setting the pins TEST [1:0] = 11. For normal converter operation, set TEST[1:0] = 00. Do not use '01' or '10'.

#### **VCOM OUTPUT**

The VCOM pin provides a voltage output equal to AVDD/2. The intended use of this output is to set the output common-mode level of the analog input drivers. The drive capability of the output is limited; therefore, the output should only be used to drive high-impedance nodes (> 1 M $\Omega$ ). In some cases, an external buffer may be necessary. A 0.1-µF bypass capacitor is recommended to reduce noise pickup.

Figure 84. VCOM Output

ADS1278-HT

SBAS447E - MARCH 2009 - REVISED APRIL 2013

### **APPLICATION INFORMATION**

To obtain the specified performance from the ADS1278, the following layout and component guidelines should be considered.

- 1. Power Supplies: The device requires three power supplies for operation: DVDD, IOVDD, and AVDD. The allowed range for DVDD is 1.65 V to 1.95 V; the range of IOVDD is 1.65 V to 3.6 V; AVDD is restricted to 4.75 V to 5.25 V. For all supplies, use a 10-µF tantalum capacitor, bypassed with a 0.1-µF ceramic capacitor, placed close to the device pins. Alternatively, a single 10-µF ceramic capacitor can be used. The supplies should be relatively free of noise and should not be shared with devices that produce voltage spikes (such as relays, LED display drivers, etc.). If a switching power-supply source is used, the voltage ripple should be low (less than 2 mV) and the switching frequency outside the passband of the converter.
- 2. **Ground Plane:** A single ground plane connecting both AGND and DGND pins can be used. If separate digital and analog grounds are used, connect the grounds together at the converter.
- 3. **Digital Inputs:** It is recommended to sourceterminate the digital inputs to the device with 50- $\Omega$  series resistors. The resistors should be placed close to the driving end of digital source (oscillator, logic gates, DSP, etc.) This placement helps to reduce ringing on the digital lines (ringing may lead to degraded ADC performance).
- 4. Analog/Digital Circuits: Place analog circuitry (input buffer, reference) and associated tracks together, keeping them away from digital circuitry (DSP, microcontroller, logic). Avoid crossing digital tracks across analog tracks to reduce noise coupling and crosstalk.
- 5. **Reference Inputs:** It is recommended to use a minimum 10- $\mu$ F tantalum with a 0.1- $\mu$ F ceramic capacitor directly across the reference inputs, VREFP and VREFN. The reference input should be driven by a low-impedance source. For best performance, the reference should have less than 3  $\mu$ V<sub>RMS</sub> in-band noise. For references with noise higher than this level, external reference filtering may be necessary.

- 6. Analog Inputs: The analog input pins must be differentially driven to achieve specified performance. A true differential driver or transformer (ac applications) can be used for this purpose. Route the analog inputs tracks (AINP, AINN) as a pair from the buffer to the converter using short, direct tracks and away from digital tracks. A 1-nF to 10-nF capacitor should be used directly across the analog input pins, AINP and AINN. A low-k dielectric (such as COG or film type) should be used to maintain low THD. Capacitors from each analog input to ground can be used. They should be no larger than 1/10 the size of the difference capacitor (typically 100 pF) to preserve the ac common-mode performance.
- 7. **Component Placement:** Place the power supply, analog input, and reference input bypass capacitors as close as possible to the device pins. This layout is particularly important for small-value ceramic capacitors. Larger (bulk) decoupling capacitors can be located farther from the device than the smaller ceramic capacitors.

<sup>(1)</sup> The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

<sup>(3)</sup> MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

<sup>(4)</sup> There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

<sup>(5)</sup> Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
