

## 3A, 18V, 1.4MHz ACOT™ Synchronous Step-Down Converter

### General Description

The RT6224D is a high-efficiency, monolithic synchronous step-down DC-DC converter that can deliver up to 3A output current from a 4.3V to 18V input supply. The RT6224D adopts ACOT™ architecture to allow the transient response to be improved and keep in constant frequency. Cycle-by-cycle current limit provides protection against shorted outputs and soft-start eliminates input current surge during start-up. Fault conditions also include output under-voltage protection, output over-voltage protection, and thermal shutdown.

### Ordering Information

Note :

Richtek products are :

- ▶ RoHS compliant and compatible with the current requirements of IPC/JEDEC J-STD-020.
- ▶ Suitable for use in SnPb or Pb-free soldering processes.

### Features

- Small Output Voltage at Light Load
- High-Side Over-Current Limit
- Integrated 90mΩ/45mΩ MOSFETs
- 4.3V to 18V Supply Voltage Range
- 1.4MHz Switching Frequency
- ACOT™ Control
- 0.6V ±1.5% Voltage Reference
- Monotonic Start-Up into Pre-Biased Outputs

### Applications

- Set Top Box
- Portable TV
- Access Point Router
- DSL Modem
- LCD TV

### Pin Configuration

### Simplified Application Circuit

## Marking Information

1X : Product Code

DNN : Date Code

## Functional Pin Description

Pin No.	Pin Name	Pin Function
1	BOOT	Bootstrap supply for high-side gate driver. Connect a 0.1 $\mu$ F ceramic capacitor between the BOOT and SW pins.
2	GND	Power ground.
3	FB	Feedback voltage input. The pin is used to set the output voltage of the converter via a resistive divider. The converter regulates $V_{FB}$ to 0.6V.
4	EN	Enable control input. Connect EN to a logic-high voltage to enable the IC or to a logic-low voltage to disable. Do not leave this high impedance input unconnected.
5	VIN	Power input. The input voltage range is from 4.3V to 18V. Must bypass with a suitable large ceramic capacitor at this pin.
6	SW	Switch node. Connected to external L-C filter.

## Functional Block Diagram

**Operation**

The RT6224D is a synchronous step-down converter with advanced constant on-time control mode. Using the ACOT control mode can reduce the output capacitance and perform fast transient response. It can minimize the component size without additional external compensation network.

**Soft-Start (SS)**

The soft-start function is used to prevent large inrush currents while the converter is being powered up. The RT6224D provides an internal soft-start feature for inrush control. During the start-up sequence, the internal capacitor is charged by an internal current source  $I_{SS}$  to generate a soft-start ramp voltage as a reference voltage to the PWM comparator. The device will initiate switching and the output voltage will smoothly ramp up to its targeted regulation voltage only after this ramp voltage is greater than the feedback voltage  $V_{FB}$  to ensure the converters have a smooth start-up. The typical soft-start time is 0.8ms.

**Output Under-Voltage Protection and Hiccup Mode**

The RT6224D includes output under-voltage protection (UVP) against over-load or short-circuited condition by constantly monitoring the feedback voltage  $V_{FB}$ . If  $V_{FB}$  drops below the under-voltage protection trip threshold (typically 75% of the internal feedback reference voltage), the UV comparator will go high to turn off both the internal high-side and low-side MOSFET switches.

If the output under-voltage condition continues for a period of time, the RT6224D will enter output under-voltage protection with hiccup mode. During hiccup mode, the IC will shut down for  $t_{HICCUP\_OFF}$  (4.5ms), and then attempt to recover automatically for  $t_{HICCUP\_ON}$  (1.5ms). Upon completion of the soft-start sequence, if the fault condition is removed, the converter will resume normal operation; otherwise, such cycle for auto-recovery will be repeated until the fault condition is cleared. Hiccup mode allows the circuit to operate safely with low input current and power dissipation, and then resume normal operation as soon as the over-load or short-circuit condition is removed.

**UVLO Protection**

To protect the chip from operating at insufficient supply voltage, the UVLO is needed. When the input voltage of  $V_{IN}$  is lower than the UVLO falling threshold voltage, the device will be lockout.

**Thermal Shutdown**

When the junction temperature exceeds the OTP threshold value, the IC will shut down the switching operation. Once the junction temperature cools down and is lower than the OTP lower threshold, the converter will autocratically resume switching.

## Absolute Maximum Ratings (Note 1)

• VIN to GND	-----	-0.3V to 20V
• SW to GND	-----	-0.3V to (VIN + 0.3V)
<10ns	-----	-5V to 25V
• BOOT to GND	-----	(VSW - 0.3V) to (VSW + 6V)
• All Other Pins	-----	-0.3V to 6V
• Power Dissipation, PD @ TA = 25°C		
TSOT-23-6 (FC)	-----	1.429W
• Package Thermal Resistance (Note 2)		
TSOT-23-6 (FC), θJA	-----	70°C/W
TSOT-23-6 (FC), θJC	-----	15°C/W
• Lead Temperature (Soldering, 10 sec.)	-----	260°C
• Junction Temperature	-----	150°C
• Storage Temperature Range	-----	-65°C to 150°C
• ESD Susceptibility (Note 3)		
HBM (Human Body Model)	-----	2kV

## Recommended Operating Conditions (Note 4)

• Supply Input Voltage, VIN	-----	4.3V to 18V
• Junction Temperature Range	-----	-40°C to 125°C
• Ambient Temperature Range	-----	-40°C to 85°C

## Electrical Characteristics

(VIN = 12V, TA = 25°C, unless otherwise specified)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit	
Shutdown Current	ISHDN	VEN = 0V	--	--	4	μA	
Quiescent Current	IQ	VEN = 2V, VFB = 1V	--	0.5	--	mA

Output Under-Voltage Delay			--	250	--	μs

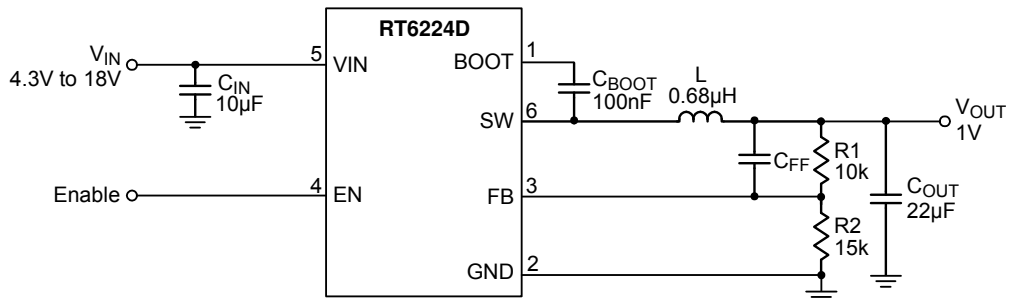

**Note 1.** Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

**Note 2.** θ<sub>JA</sub> is measured under natural convection (still air) at T<sub>A</sub> = 25°C with the component mounted on a high effective-thermal-conductivity four-layer test board on a JEDEC 51-7 thermal measurement standard. The first layer is filled with copper. θ<sub>JC</sub> is measured at the lead of the package.

**Note 3.** Devices are ESD sensitive. Handling precaution is recommended.

**Note 4.** The device is not guaranteed to function outside its operating conditions.

## Typical Application Circuit

**Table 1. Suggested Component Values**

V <sub>OUT</sub> (V)	R <sub>1</sub> (kΩ)	R <sub>2</sub> (kΩ)	L (µH)	C <sub>OUT</sub> (µF)	C <sub>FF</sub> (pF)
5	110	15	2	22	12
3.3	115	25.5	1.8	22	12
2.5	25.5	8.06	1.5	22	NC
1	10	15	0.68	22	NC

Note : All the input and output capacitors are the suggested values, referring to the effective capacitances, subject to any de-rating effect, like a DC bias.

**Typical Operating Characteristics**

**Power On from EN**

**Power Off from EN**

**Power On from VIN**

**Power Off from VIN**

## Application information

### Inductor Selection

Selecting an inductor involves specifying its inductance and also its required peak current. The exact inductor value is generally flexible and is ultimately chosen to obtain the best mix of cost, physical size, and circuit efficiency. Lower inductor values benefit from reduced size and cost and they can improve the circuit's transient response, but they increase the inductor ripple current and output voltage ripple and reduce the efficiency due to the resulting higher peak currents. Conversely, higher inductor values increase efficiency, but the inductor will either be physically larger or have higher resistance since more turns of wire are required and transient response will be slower since more time is required to change current (up or down) in the inductor. A good compromise between size, efficiency, and transient response is to use a ripple current ( $\Delta I_L$ ) about 20% to 50% of the desired full output load current. Calculate the approximate inductor value by selecting the input and output voltages, the switching frequency ( $f_{SW}$ ), the maximum output current ( $I_{OUT(MAX)}$ ) and estimating a  $\Delta I_L$  as some percentage of that current.

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times \Delta I_L}$$

Once an inductor value is chosen, the ripple current ( $\Delta I_L$ ) is calculated to determine the required peak inductor current.

$$\Delta I_L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times f_{SW} \times L}$$

$$I_{L(PEAK)} = I_{OUT(MAX)} + \frac{\Delta I_L}{2}$$

$$I_{L(VALLY)} = I_{OUT(MAX)} - \frac{\Delta I_L}{2}$$

Considering the Typical Operating Circuit for 1V output at 3A and an input voltage of 12V, using an inductor ripple of 1A (50%), the calculated inductance value is :

$$L = \frac{1V \times (12 - 1V)}{12 \times 1400kHz \times 1} = 0.65\mu H$$

The ripple current was selected at 1A and, as long as we use the calculated 0.68 $\mu$ H inductance, that should be the actual ripple current amount. The ripple current and required peak current as below :

$$\Delta I_L = \frac{1V \times (12 - 1V)}{12 \times 1400kHz \times 0.68\mu H} = 0.96A$$

$$\text{and } I_{L(PEAK)} = 3A + \frac{0.96}{2} = 3.48A$$

Inductor saturation current should be chosen over IC's current limit.

### Input Capacitor Selection

The input filter capacitors are needed to smooth out the switched current drawn from the input power source and to reduce voltage ripple on the input. The actual capacitance value is less important than the RMS current rating (and voltage rating, of course). The RMS input ripple current ( $I_{RMS}$ ) is a function of the input voltage, output voltage, and load current :

$$I_{RMS} = I_{OUT(MAX)} \times \frac{V_{OUT}}{V_{IN}} \sqrt{\frac{V_{IN}}{V_{OUT}} - 1}$$

Ceramic capacitors are most often used because of their low cost, small size, high RMS current ratings, and robust surge current capabilities. However, take care when these capacitors are used at the input of circuits supplied by a wall adapter or other supply connected through long, thin wires. Current surges through the inductive wires can induce ringing at the RT6224D input which could potentially cause large, damaging voltage spikes at  $V_{IN}$ . If this phenomenon is observed, some bulk input capacitance may be required. Ceramic capacitors (to meet the RMS current requirement) can be placed in parallel with other types such as tantalum, electrolytic, or polymer (to reduce ringing and overshoot).

Choose capacitors rated at higher temperatures than required. Several ceramic capacitors may be paralleled to meet the RMS current, size, and height requirements of the application. The typical operating circuit use 10 $\mu$ F and one 0.1 $\mu$ F low ESR ceramic capacitors on the input.

**Output Capacitor Selection**

The RT6224D is optimized for ceramic output capacitors and best performance will be obtained using them. The total output capacitance value is usually determined by the desired output voltage ripple level and transient response requirements for sag (undershoot on positive load steps) and soar (overshoot on negative load steps).

**Output Ripple**

Output ripple at the switching frequency is caused by the inductor current ripple and its effect on the output capacitor's ESR and stored charge. These two ripple components are called ESR ripple and capacitive ripple. Since ceramic capacitors have extremely low ESR and relatively little capacitance, both components are similar in amplitude and both should be considered if ripple is critical.

$$V_{RIPPLE} = V_{RIPPLE(ESR)} + V_{RIPPLE(C)}$$

$$V_{RIPPLE(ESR)} = \Delta I_L \times R_{ESR}$$

$$V_{RIPPLE(C)} = \frac{\Delta I_L}{8 \times C_{OUT} \times f_{SW}}$$

For the Typical Operating Circuit for 1V output and an inductor ripple of 0.96A, with 22μF output capacitance each with about 5mΩ ESR including PCB trace resistance, the output voltage ripple components are :

$$V_{RIPPLE(ESR)} = 0.96A \times 5m\Omega = 4.8mV$$

$$V_{RIPPLE(C)} = \frac{0.96A}{8 \times 22\mu F \times 1400kHz} = 3.9mV$$

$$V_{RIPPLE} = 4.8mV + 3.9mV = 8.7mV$$

**Output Transient Undershoot and Overshoot**

In addition to voltage ripple at the switching frequency, the output capacitor and its ESR also affect the voltage sag (undershoot) and soar (overshoot) when the load steps up and down abruptly. The ACOT™ transient response is very quick and output transients are usually small.

However, the combination of small ceramic output capacitors (with little capacitance), low output voltages (with little stored charge in the output capacitors), and low duty cycle applications (which require high inductance to get reasonable ripple currents with high input voltages) increases the size of voltage variations in response to very quick load changes. Typically, load changes occur slowly with respect to the IC's 1400kHz switching frequency.

But some modern digital loads can exhibit nearly instantaneous load changes and the following section shows how to calculate the worst-case voltage swings in response to very fast load steps.

The output voltage transient undershoot and overshoot each have two components : the voltage steps caused by the output capacitor's ESR, and the voltage sag and soar due to the finite output capacitance and the inductor current slew rate. Use the following formulas to check if the ESR is low enough (typically not a problem with ceramic capacitors) and the output capacitance is large enough to prevent excessive sag and soar on very fast load step edges, with the chosen inductor value.

The amplitude of the ESR step up or down is a function of the load step and the ESR of the output capacitor :

$$V_{ESR\_STEP} = \Delta I_{OUT} \times R_{ESR}$$

The amplitude of the capacitive sag is a function of the load step, the output capacitor value, the inductor value, the input-to-output voltage differential, and the maximum duty cycle. The maximum duty cycle during a fast transient is a function of the on-time and the minimum off-time since the ACOT™ control scheme will ramp the current using on-times spaced apart with minimum off-times, which is as fast as allowed. Calculate the approximate on-time (neglecting parasitics) and maximum duty cycle for a given input and output voltage as :

$$t_{ON} = \frac{V_{OUT}}{V_{IN} \times f_{SW}} \text{ and } D_{MAX} = \frac{t_{ON}}{t_{ON} + t_{OFF(MIN)}}$$

The actual on-time will be slightly longer as the IC compensates for voltage drops in the circuit, but we can neglect both of these since the on-time increase compensates for the voltage losses. Calculate the output voltage sag as :

$$V_{SAG} = \frac{L \times (\Delta I_{OUT})^2}{2 \times C_{OUT} \times (V_{IN(MIN)} \times D_{MAX} - V_{OUT})}$$

The amplitude of the capacitive soar is a function of the load step, the output capacitor value, the inductor value and the output voltage :

$$V_{SOAR} = \frac{L \times (\Delta I_{OUT})^2}{2 \times C_{OUT} \times V_{OUT}}$$

### Feed-Forward Capacitor (C<sub>FF</sub>)

The RT6224D is optimized for ceramic output capacitors and for low duty cycle applications. However for high-output voltages, with high feedback attenuation, the circuit's response becomes over-damped and transient response can be slowed. In high-output voltage circuits (V<sub>OUT</sub> > 3.3V) transient response is improved by adding a small “feed-forward” capacitor (C<sub>FF</sub>) across the upper FB divider resistor (Figure 1), to increase the circuit's Q and reduce damping to speed up the transient response without affecting the steady-state stability of the circuit. Choose a suitable capacitor value that following below step.

- ▶ Get the BW the quickest method to do transient response form no load to full load. Confirm the damping frequency. The damping frequency is BW.

Figure 1. C<sub>FF</sub> Capacitor Setting

- ▶ C<sub>FF</sub> can be calculated base on below equation :

$$C_{FF} = \frac{1}{2 \times 3.1412 \times R1 \times BW \times 0.8}$$

### Internal Soft-Start (SS)

The RT6224D soft-start uses an internal soft-start time 800μs.

Following below equation to get the minimum capacitance range in order to avoid UV occur.

$$t = \frac{C_{OUT} \times V_{OUT} \times 0.6 \times 1.2}{(I_{LIM} - \text{Load Current}) \times 0.8}$$

$$t \leq 800\mu s$$

### Enable Operation (EN)

For automatic start-up the EN pin can be connected to V<sub>IN</sub>, through a 100kΩ resistor. Its large hysteresis band makes EN useful for simple delay and timing circuits. EN can be externally pulled to V<sub>IN</sub> by adding a resistor-capacitor delay (R<sub>EN</sub> and C<sub>EN</sub> in Figure 2). Calculate the delay time using EN's internal threshold where switching operation begins (1.5V, typical).

An external MOSFET can be added to implement digital control of EN when no system voltage above 2V is available (Figure 3). In this case, a 100kΩ pull-up resistor, R<sub>EN</sub>, is connected between V<sub>IN</sub> and the EN pin. The MOSFET Q1 will be under logic control to pull down the EN pin. To prevent enabling circuit when V<sub>IN</sub> is smaller than the V<sub>OUT</sub> target value or some other desired voltage level, a resistive voltage divider can be placed between the input voltage and ground and connected to EN to create an additional input under voltage lockout threshold (Figure 4).

Figure 2. External Timing Control

Figure 3. Digital Enable Control Circuit

Figure 4. Resistor Divider for Lockout Threshold Setting

**Output Voltage Setting**

Set the desired output voltage using a resistive divider from the output to ground with the midpoint connected to FB. The output voltage is set according to the following equation :

$$V_{OUT} = 0.6 \times (1 + R1 / R2)$$

Figure 5. Output Voltage Setting

Place the FB resistors within 5mm of the FB pin. Choose R2 between 10kΩ and 100kΩ to minimize power consumption without excessive noise pick-up and calculate R1 as follows :

$$R1 = \frac{R2 \times (V_{OUT} - 0.6)}{0.6}$$

For output voltage accuracy, use divider resistors with 1% or better tolerance.

**External BOOT Bootstrap Diode**

When the input voltage is lower than 5.5V it is recommended to add an external bootstrap diode between VIN (or VINR) and the BOOT pin to improve enhancement of the internal MOSFET switch and improve efficiency. The bootstrap diode can be a low cost one such as 1N4148 or BAT54.

**External BOOT Capacitor Series Resistance**

The internal power MOSFET switch gate driver is optimized to turn the switch on fast enough for low power loss and good efficiency, but also slow enough to reduce EMI. Switch turn-on is when most EMI occurs since V<sub>SW</sub> rises rapidly. During switch turn-off, SW is discharged relatively slowly by the inductor current during the deadtime between high-side and low-side switch on-times. In some cases it is desirable to reduce EMI further, at the expense of some additional power dissipation. The switch turn-on can be slowed by placing a small (<47Ω) resistance

between BOOT and the external bootstrap capacitor. This will slow the high-side switch turn-on and V<sub>SW</sub>'s rise. To remove the resistor from the capacitor charging path (avoiding poor enhancement due to undercharging the BOOT capacitor), use the external diode shown in Figure 6 to charge the BOOT capacitor and place the resistance between BOOT and the capacitor/diode connection.

Figure 6. External Bootstrap Diode

**Over-Temperature Protection**

The RT6224D features an over-temperature protection (OTP) circuitry to prevent from overheating due to excessive power dissipation. The OTP will shut down switching operation when junction temperature exceeds 160°C. Once the junction temperature cools down by approximately 20°C, the converter will resume operation. To maintain continuous operation, the maximum junction temperature should be lower than 125°C.

**Under-Voltage Protection**

**Hiccup Mode**

The RT6224D provides Hiccup Mode under-voltage protection (UVP). When the V<sub>FB</sub> voltage drops below 0.45V, the UVP function will be triggered to shut down switching operation. If the UVP condition remains for a period, the RT6224D will retry automatically. When the UVP condition is removed, the converter will resume operation. The UVP is disabled during soft-start period.

**Thermal Considerations**

The junction temperature should never exceed the absolute maximum junction temperature T<sub>J(MAX)</sub>, listed under Absolute Maximum Ratings, to avoid permanent damage to the device. The maximum allowable power dissipation depends on the thermal resistance of the IC package, the PCB layout, the rate of surrounding airflow,

and the difference between the junction and ambient temperatures. The maximum power dissipation can be calculated using the following formula :

$$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$$

where  $T_{J(MAX)}$  is the maximum junction temperature,  $T_A$  is the ambient temperature, and  $\theta_{JA}$  is the junction-to-ambient thermal resistance.

For continuous operation, the maximum operating junction temperature indicated under Recommended Operating Conditions is 125°C. The junction-to-ambient thermal resistance,  $\theta_{JA}$ , is highly package dependent. For a TSOT-23-6 (FC) package, the thermal resistance,  $\theta_{JA}$ , is 70°C/W on a standard JEDEC 51-7 high effective-thermal-conductivity four-layer test board. The maximum power dissipation at  $T_A = 25^\circ\text{C}$  can be calculated as below :

$$P_{D(MAX)} = (125^\circ\text{C} - 25^\circ\text{C}) / (70^\circ\text{C}/\text{W}) = 1.429\text{W}$$

The maximum power dissipation depends on the operating ambient temperature for the fixed  $T_{J(MAX)}$  and the thermal resistance,  $\theta_{JA}$ . The derating curves in Figure 7 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Figure 7. Derating Curve of Maximum Power Dissipation

### Layout Considerations

For best performance of the RT6224D, the following layout guidelines must be strictly followed.

- ▶ Input capacitor must be placed as close to the IC as possible.
- ▶ SW should be connected to inductor by wide and short trace. Keep sensitive components away from this trace. Suggestion layout trace wider for thermal.

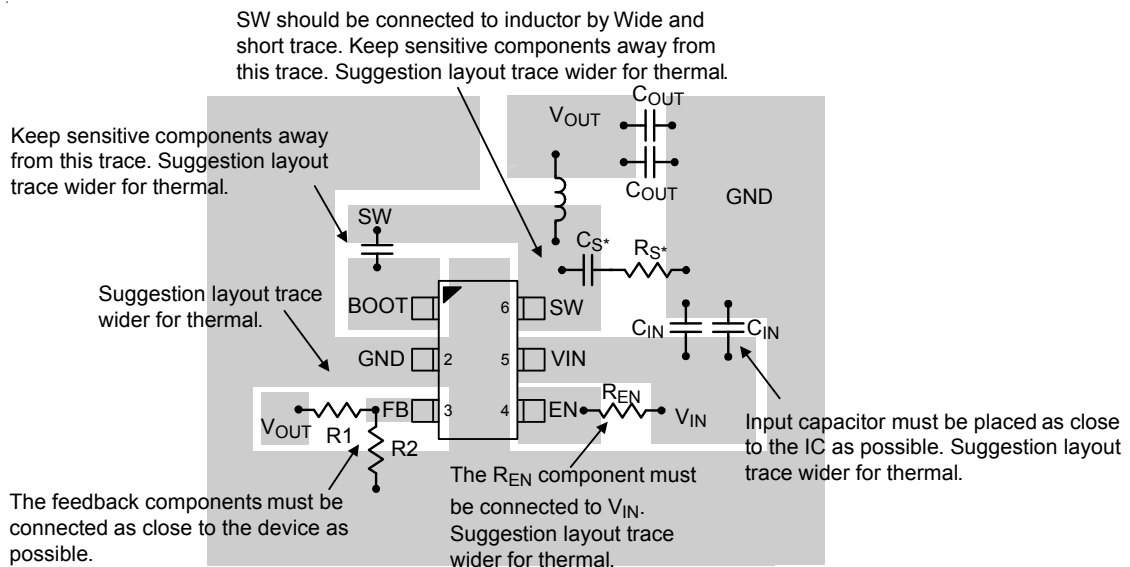

Figure 8. PCB Layout Guide
