ABB

MPR0712DCR12Z02A Power Supply
Input: -44VDC to -72VDC; Output: +12VDC, 700W; Auxiliary Voltage 12VDC @ 2A

The MPR0712DC series provides high efficiency isolated power from the DC input mains. The industry standard PMBus® compliant I2C communications bus offers a full range of control and monitoring capabilities. The SMBAlert signal pin automatically alerts customers of any state change within the power supply.

Application

- 12VDC distributed power architectures
- Mid-End Servers
- Blade Servers
- Network Equipment

- Network Attached Storage
- Storage Area Networks
- Routers/Switches
- Enterprise Networks
- Advanced workstations

Features

- Compliant to RoHS II EU "Directive 2011/65/E (-Z versions)
- Compliant to REACH Directive (EC) No 1907/2006
- 2.15" x 9.0" x 1.57"
- Efficiency : 94% at 50% load
- 12VDC Regulation: set point ±0.33%, overall ±1%
- Turn-On overshoot: within regulation
- Active current share on 12V with OR'ing function
- Remote sense on the 12V main output
- Hot insertion/removal (hot plug)

- 12VDC secondary Regulation: ± 2.5%
- Hardware recoverable latched 12VDC overvoltage
- Auto recoverable overload & over temperature
- Firmware adjustable overload set point of 12V output
- Operating temperature: -5°C to 50°C
- Digital status & control: PMBus® serial bus
- Conducted EMI: class A with 6dB margin
- Meets EN6100 immunity and transient standards
- Safety: UL, CAN/CSA, IEC, TUV, IEC62368-1

Technical Specifications

Absolute Maximum Ratings

Stresses over the absolute maximum ratings can cause permanent damage to the device. These are absolute stress ratings only. Functional operation of the device is not implied at these or any other conditions over those given in the operations sections of the data sheet. Exposure to absolute maximum ratings for extended periods can adversely affect the device reliability.

Parameter	Device	Min	Max	Unit
Input Voltage: Continuous	V_{IN}	-44	-72	V_{DC}
Operating Ambient Temperature	T_A	-5	50[1]	°C
Storage Temperature	T_{STG}	-40	85	°C
I/O Isolation voltage (100% factory Hi-Pot tested)			1000	V_{DC}

[1] 700W, -44 to-72VDC. De-rating above 48°C for reverse model

Status and Control signals

Signal Name	I/O	Description	Interface Details
INPUT_OK (DC Source)	Output	The signal output is driven high when input source is available and within acceptable limits. The output is driven low to indicate loss of input power.	Pulled up internally via 10K to 3.3VDC. A logic high >3.0VDC A logic low < 0.8VDC Driven low by internal CMOS buffer.
PW_OK (Output OK)	Output	The signal is asserted, driven high, by the power supply to indicate that main output is valid. If main output failed, then this output will be hi-Z or driven low. The output is driven low to indicate that the Main output is outside of lower limit of regulation (<10.8VDC).	Pulled up internally via 10K to 3.3VDC. A logic high >3.0VDC A logic low < 0.8VDC Driven low by internal CMOS buffer.
SMB_ALERT (FAULT/WARNING)	Output	The signal output is driven low to indicate that the power supply has detected a warning or fault and is intended to alert the system. This output must be driven high when the power is operating correctly (within specified limits). The signal will revert to a high level when the warning/fault stimulus (that caused the alert) is removed.	Pulled up internally via 10K to 3.3VDC. A logic high >3.0VDC A logic low < 0.8VDC Driven low by internal CMOS buffer.
PRESENT_L （Power Supply Absent)	Output	The signal is used to detect the presence (installed) of a PSU by the host system. The signal is connected to PSU logic SGND within the power module.	Passive connection to +VSB_Return. A logic low < 0.8VDC
PS_ON (Power Supply Enable/Disable)	Input	This signal is pulled up internally to the internal housekeeping supply（within the power supply). The power supply main 12VDC output will be enabled when this signal is pulled low to +VSB_Return. In the low state the signal input shall not source more than 1mA of current. The 12VDC output will be disabled when the input is driven higher than 2.4V, or open circuited. Cycling this signal shall clear latched fault conditions.	Pulled up internally via 10K to 3.3VDC. A logic high >3.0VDC A logic low < 0.8VDC Input is via CMOS Schmitt trigger buffer.
PS_KILL	Input	This signal is used during hot swap to disable the main output during hot swap extraction. The input is pulled up internally to the internal housekeeping supply (within the power supply). The signal is provided on a short (lagging pin) and should be connected to +VSB_Return.	Pulled up internally via 10K to 3.3VDC. A logic high >3.0VDC A logic low < 0.8VDC Input is via CMOS Schmitt trigger buffer
ADDR (Address Select)	Input	An analog input that is used to set the address of the internal slave devices (EEPROM and microprocessor) used for digital communications. Connection of a suitable resistor to +VSB_Return, in conjunction with an internal resistor divider chain, will configure the required address.	DC voltage between the limits of 0 and +3.3VDC.
SCL (Serial Clock)	Both	A serial clock line compatible with PMBus® Power Systems Management Protocol Part 1 – General Requirements Rev 1.2. No additional internal capacitance is added that would affect the speed of the bus. The signal is provided with a series isolator device to disconnect the internal power supply bus if the power module is unpowered.	V_{IL} is 0.8V maximum V_{OL} is 0.4V maximum when sinking 3mA V_{IH} is 2.1V minimum
SDA (Serial Data)	Both	A serial data line compatible with PMBus® TPower Systems Management Protocol Part 1 – General Requirements Rev 1.2. The signal is provided with a series isolator device to disconnect the internal power supply bus if the power module is unpowered.	V_{IL} is 0.8V maximum V_{OL} is 0.4V maximum when sinking 5mA V_{IH} is 2.1V minimum
V1_SENSE V1SENSE_RTN	Input	Remote sense connections intended to be connected at and sense the voltage at the point of load. The voltage sense will interact with the internal module regulation loop to compensate for voltage drops due to connection resistance between the output connector and the load. If remote sense compensation is not required, then the voltage can be configured for local sense by: 1. V1_SENSE directly connected to power blades 6 to 10 (inclusive) 2. V1_SENSE_RTN directly connected to power blades 1 to 5 (inclusive)	Compensation for a up to 0.12VDC total connection drop (output and return connections).
ISHARE	Bi-Directional Analogue Bus	The current sharing signal is connected between sharing units (forming an ISHARE bus). It is an input and/or an output (bi-directional analogue bus) as the voltage on the line controls the current share between sharing units. A power supply will respond to a change in this voltage, but a power supply can also change the voltage depending on the load drawn from it. On a single unit the voltage on the pin (and the common ISHARE bus would read 8.74VDC at 100% load (module capability). For two identical units sharing the same 100% load this would read 4.37VDC for perfect current sharing (i.e. 50% module load capability per unit). Analogue voltage: +10V maximum; 10K to +12V_RTN

Visual Indicators (LEDs)

Input (Green), Output (Bicolor Green/Amber)

Status Indicators

LED NAME	LED MODE	LED STATE/ OPERATION	DESCRIPTION
Input	OK	Solid Green	Input voltage operating within normal specified range
Input	OV/UV Warning	Blinking Green	Input voltage operating in: 1) overvoltage warning, 2) under voltage warning range, or 3) above overvoltage range
Input	OFF or Fault	Off	Input voltage operating: 1) below under voltage range, or 2) not present
Output	Power Good	Solid Green	Main output & standby output enabled with no power supply warning or fault detected
Output	Standby	Blinking Green	Standby output enabled with no power supply warning or fault detected
Output	Warning	Blinking Amber	Power supply warning detected as per PMBus® STATUS_X reporting bytes*
Output	Fault	Solid Amber	Power supply fault detected as per PMBus® STATUS_X reporting
Output	OFF	Off	Input below under voltage range

* LED fault/warning operation follows PMBus fault/warning reporting status flags but will not be "sticky" (i.e., if the fault stimulus is removed, even though the actual fault/warning is still showing [still "sticky" and not cleared], the relevant LED will revert to normal (non-fault) operation.

Technical Specifications

Timing Specifications

Turn-on delay & output rise time
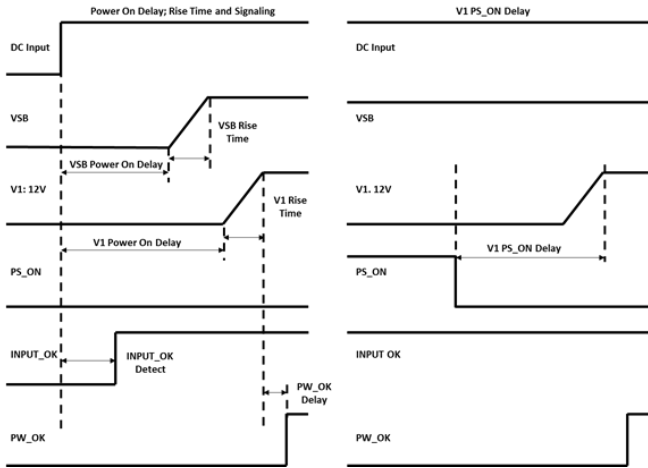

| Time	Min (ms)	Max (ms)
Vsb Rise Time	20	60
V1 Rise Time	20	80
Vsb Power-on Delay	-	2000
V1 Power-on Delay	-	2000
V1 PS_ON Delay		150
V1 PW_OK Delay	100	300
INPUT_OK Detect	300	1000

The turn-on delay after application of DC input within the operating range shall as defined in the following tables. The output rise times shall be measured from 10% of the nominal outputs to the lower limit of the regulation band as defined in the following tables.

Power removal holdup, fall time and signaling
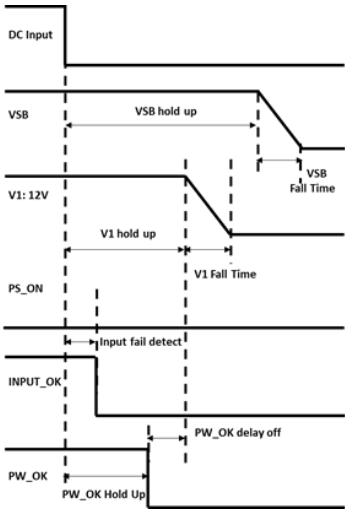

Power Removal Timing	Min	Typ	Max	Notes
Vsb holdup with remote off	40ms		-	
V1 holdup (effective Total)	-	2ms	-	700W
Input fail detect	-	3ms	-	700W, -53V$_{DC}$
PW_OK delay off	1ms		-	700W
PW_OK Hold up	-	1ms	-	700W

Turn-off (Shutdown by PS_ON)
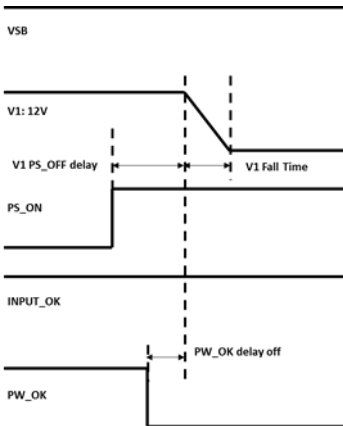

Turn-off Timing	Min	Max	Notes
V1 Fall time	-	-	Must be mono-tonic
V1 PS_OFF delay	-	6ms	
PW_OK delay off	1ms		

Technical Specifications

Design Features

Serial Bus Communications

The I²C interface facilitates the monitoring and control of various operating parameters within the unit and transmits these on demand over an industry standard I²C Serial bus.

All signals are referenced to 'SGND'.

Pull-up resistors: The clock, data, and SMBAlert lines do not have any internal pull-up resistors inside the rectifier. The customer is responsible for ensuring that the transmission impedance of the communications lines complies with I2C and SMBus standards.

Serial Clock (SCL): The clock pulses on this line are generated by the host that initiates communications across the I²C Serial bus. This signal needs to be pulled HI externally through a resistor as necessary to ensure that rise and fall time timing and the maximum sink current complies to the I²C / SMBus specifications.

Serial Data (SDA): This line is a bi-directional data line. This signal needs to be pulled HI externally through a resistor as necessary to ensure that rise and fall time timing and the maximum sink current complies to the I²C / SMBus specifications.

Digital Feature Descriptions

PMBus® compliance: The rectifier is fully compliant to the Power Management Bus (PMBus®) rev1.2 requirements. This Specification can be obtained from www.pmbus.org.

'Manufacturer Specific' commands are used to support additional instructions that are not in the PMBus™ specification.

All communication over the PMBus interface must support the Packet Error Checking (PEC) scheme. The PMBus master must generate the correct PEC byte for all transactions, and check the PEC byte returned by the rectifier.

Non-volatile memory is used to store configuration settings. Not all settings programmed into the device are automatically saved into this non-volatile memory. Only those specifically identified as capable of being stored can be saved. (see the Table of Commands for which command parameters can be saved to non-volatile storage).

Non-supported commands: Non supported commands are flagged by setting the appropriate STATUS bit and issuing a SMBAlert to the 'host' controller.

If a non-supported read is requested the rectifier will return 0x00h for data.

Data out-of-range: The rectifier validates data settings and sets the data out-of-range bit and SMBAlert if the data is not within acceptable range.

Master/Slave: The 'host controller' is always the MASTER. Rectifiers are always SLAVES. SLAVES cannot initiate communications or toggle the Clock. SLAVES also must respond expeditiously at the command of the MASTER as required by the clock pulses generated by the MASTER.

Clock stretching: The 'slave' µController inside the rectifier may initiate clock stretching if it is busy and it desires to delay the initiation of any further communications. During the clock stretch the 'slave' may keep the clock LO until it is ready to receive further instructions from the host controller.

The maximum clock stretch interval is 25ms.

The host controller needs to recognize this clock stretching, and refrain from issuing the next clock signal, until the clock line is released, or it needs to delay the next clock pulse beyond the clock stretch interval of the rectifier. Note that clock stretching can only be performed after completion of transmission of the

9th ACK bit, the exception being the START command.
I²C Bus Lock-Up detection: The device will abort any transaction and drop off the bus if it detects the bus being held low for more than 35ms.

Communications speed: Both 100kHz and 400kHz clock rates are supported. The rectifiers default to the 100kHz clock rate.

Packet Error Checking (PEC): The rectifier will not respond to commands without the trailing PEC. The integrity of communications is compromised if packet error correction is not employed. There are many functional features, including turning off the main output, that require validation to ensure that the desired command is executed.

PEC is a CRC-8 error-checking byte, based on the polynomial $C(x) = x^8 + x^2 + x + 1$, in compliance with PMBus™ requirements. The calculation is based in all message bytes, including the originating write address and command bytes preceding read instructions. The PEC is appended to the message by the device that supplied the last byte.

SMBAlert: The µC driven SMBAlert signal informs the 'master/host' controller that either a STATE or ALARM change has occurred. Normally this signal is HI. The signal will change to its LO level if the rectifier has changed states and the signal will be latched LO until the rectifier receives a 'clear_faults' instruction.

The signal will be triggered for any state change, including the following conditions:

- VIN under or over voltage
- VOUT under or over voltage
- IOUT over current
- Over Temperature warning or fault
- Fan Failure
- Communication error
- PEC error
- Invalid command

SMBAlert is asserted during power up to notify the master that a new rectifier has been added to the bus.

The rectifier will clear the SMBAlert signal (release the signal to its HI state) upon the following events:

- Receiving a CLEAR_FAULTS command
- Bias power to the processor is recycled

The rectifier will re-assert the Alert line if the internal state of the rectifier has changed, even if that information cannot be reported by the status registers until a clear_faults is issued by the host. If the Alert asserts, the host should respond by issuing a clear_faults to retire the alert line (this action also provides the ability to change the status registers). This action triggers another Alert assertion because the status registers changed states to report the latest state of the rectifier. The host is now able to read the latest reported status register information and issue a clear_faults to retire the Alert signal.

Technical Specifications

Re-initialization: The I2C code is programmed to re-initialize if no activity is detected on the bus for 5 seconds. Reinitialization is designed to guarantee that the I2C μController does not hang up the bus. Although this rate is longer than the timing requirements specified in the SMBus specification, it had to be extended in order to ensure that a re-initialization would not occur under normal transmission rates. During the few μseconds required to accomplish reinitialization the I2C μController may not recognize a command sent to it. (i.e. a start condition).

Read back delay: The rectifier issues the SMBAlert notification as soon as the first state change occurred. During an event a few different states can be transitioned to before the final event occurs. If a read back is implemented rapidly by the host a successive SMBAlert could be triggered by the transitioning state of the rectifier. In order to avoid successive SMBAlert s and read back and also to avoid reading a transitioning state, it is prudent to wait more than 2 seconds after the receipt of a SMBAlert before executing a read back. This delay will ensure that only the final state of the rectifier is captured.

Successive read backs: Successive read backs to the rectifier should not be attempted at intervals faster than every one second. This time interval is sufficient for the internal processors to update their data base so that successive reads provide fresh data.

Global Broadcast: This is a powerful command because it instructs all rectifiers to respond simultaneously. A read instruction should never be accessed globally. The rectifier should issue an 'invalid command' state if a 'read' is attempted globally.

For example, changing the 'system' output voltage requires the global broadcast so that all paralleled rectifiers change their output simultaneously. This command can also turn OFF the 'main' output or turn ON the 'main' output of all rectifiers simultaneously. Unfortunately, this command does have a side effect. Only a single rectifier needs to pull down the ninth acknowledge bit. To be certain that each rectifier responded to the global instruction, a READ instruction should be executed to each rectifier to verify that the command properly executed. The GLOBAL BROADCAST command should only be executed for write instructions to slave devices.

PMBus® Commands

Standard instruction: Up to two bytes of data may follow an instruction depending on the required data content. Analog data is always transmitted as LSB followed by MSB. PEC is mandatory and includes the address and data fields.

1	8	1	1	8	1
S	Slave address	Wr	A	Command Code	A

8	1	8	1	8	1	1
Low data byte	A	High data byte	A	PEC	A	P

| ☐ Master to Slave | ⌐ ⌐ Slave to Master |
SMBUS annotations; S – Start , Wr – Write, Sr – re-Start, Rd – Read, A – Acknowledge, NA – not-acknowledged, P – Stop

Standard READ: Up to two bytes of data may follow a READ request depending on the required data content. Analog data is always transmitted as LSB followed by MSB. PEC is mandatory and includes the address and data fields.

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code	A

1	7	1	1	8	1
Sr	Slave Address	Rd	A	LSB	A

8	1	8	1	1
MSB	A	PEC	NA	P

Block communications: When writing or reading more than two bytes of data at a time BLOCK instruction for WRITE and READ commands are used instead of the Standard Instructions above to write or read any number of bytes greater than two.

Block write format:

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code	A

8	1	8	1	8	1
Byte count = N	A	Data 1	A	Data 2	A

8	1	8	1	8	1	1
....	A	Data N	A	PEC	A	P

Block read format:

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code	A

1	7	1	1
Sr	Slave Address	Rd	A

8	1	8	1	8	1
Byte count = N	A	Data 1	A	Data 2	A

8	1	8	1	8	1	1
....	A	Data N	A	PEC	NA	P

Linear Data Format: The definition is identical to Part II of the PMBus Specification. All standard PMBus values, except for output voltage related functions, are represented by the linear format described below. Output voltage functions are represented by a 16-bit mantissa. Output voltage has an E=-9 constant exponent.

The Linear Data Format is a two-byte value with an 11-bit, two's complement mantissa and a 5-bit, two's complement exponent or scaling factor, its format is shown below.

The relationship between the Mantissa, Exponent, and Actual

Data Byte High								Data Byte Low							
Bit	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
	Exponent (E)					Mantissa (M)									

Value (V) is given by the following equation:

$V = M * 2^E$

Where: V is the value, M is the 11-bit, two's complement mantissa, E is the 5-bit, two's complement exponent

Standard features

Supported features that are not readable: The commands below are supported at the described setting, but they cannot be read back through the command set.

Status and Alarm registers: The registers are updated with the latest operational state of the rectifier. For example, whether the output is ON or OFF is continuously updated with the latest state of the rectifier. However, alarm information is maintained until a clear_fault command is received from the host. For example, the shutdown or OC_fault bits stay in their alarmed state until the host clears the registers.

A clear_faults clears all registers. If a fault persists after the clear_faults is commanded, the register bit annunciating the fault is reset again.

Command	Comments
ON_OFF_CONFIG (0x02)	Both the CNTL pin, and the OPERATION command, enabling or disabling the output, are supported. Other options are not supported.
Capability (0x19)	400KHz, ALERT#
PMBus revision (0x98)	1.2

PMBus® Addressing

Hardware setting: The signal pin, ADDR(A3) configure the address of the power supply. Note that the ground reference for addressing is Signal Ground (SGND).

Internally each power supply has a 10kΩ pull up resistor between the ADDR pin and 3.3V. The resistance between the ADDR pin and SGND shall determine the values for A2-A0. The nominal resistor and corresponding voltage value for each position is tabulated below.

ADDR PIN (A3) resistor to GND (K-ohm)	Nominal voltage(V)	Address		
		A2	A1	A0
0.82	0.25	0	0	0
2.7	0.70	0	0	1
5.6	1.18	0	1	0
8.2	1.48	0	1	1
15	1.98	1	0	0
27	2.41	1	0	1
56	2.80	1	1	0
180	3.12	1	1	1

Firmware setting:

Device	Address	Address Bit Assignments (Most to Least Significant)							
		7	6	5	4	3	2	1	0
µP	B0 – BF	1	0	1	1	A2	A1	A0	R/W
Broadcast	00	0	0	0	0	0	0	0	0
EEprom	A0 – AF	1	0	1	0	A2	A1	A0	R/W
		MSB							LSB

Technical Specifications

Command Descriptions

Operation (0x01): Turns the 12V output ON or OFF. The default state is ON at power up. Only the following data bytes are supported:

FUNCTION	DATA BYTE
Unit ON	0x80
Unit OFF	0x00

To RESET the rectifier using this command, command the rectifier OFF, wait at least 2 seconds, and then command the rectifier back ON. All alarms and shutdowns are cleared during a restart.

Clear_faults (0x03): Clears all STATUS and FAULT registers and resets the Alert# line of the I2C side in control. The I2C side not in control cannot clear registers in the power supply. This command is always executable.

If a fault persists after the issuance of the clear_faults command, the specific registers indicating the fault first clears

have their parameters read, regardless of the write_protect settings. The contents of this register cannot be stored into non-volatile memory using the Store_user_code may command. The but then get set again to indicate that the unit is still in the fault state.

WRITE_PROTECT register (0x10): Used to control writing to the PMBus device. The intent of this command is to provide protection against accidental changes. All supported commands default setting of this register is enable_all_writes, write_protect 0x00h. The write_protect command must always be accepted.

FUNCTION	DATA BYTE
Enable all writes	00
Disable all writes except write_protect	80
Disable all writes except write_protect and OPERATION	40

Restore_Default_All (0x12): Restores all operating register values and responses to the factory default parameters set in the rectifier. The factory default cannot be changed.

Restore_default_code (0x14): Restore only a specific register parameter into the operating register section of the rectifier.

Store_user_code (0x17): Changes the user default setting of a single register. In this fashion some protection is offered to

ensure that only those registers that are desired to be changed are in fact changed.

Restore_user_code (0x18): Restores the user default setting of a single register.

Vout_mode (0x20): This is a 'read only' register. The upper three bits specify the supported data format, in this case Linear mode. The lower five bits specify the exponent of the data in two's complement binary format for output voltage related commands, such as Vout_command. These commands have a 16 bit mantissa. The exponent is fixed by the rectifier

Mode	Bits [7:5]	Bits [4:0] (Parameter)
Linear	000b	xxxxxb

and is returned by this command.

Vin_ON (0x35): This is a 'read only' register that informs the controller at what input voltage level the rectifier turns ON. The default value is tabulated in the data section.

Vin_OFF (0x36): This is a 'read only' register that informs the controller at what input voltage level the rectifier turns OFF. The default value is tabulated in the data section.

Fan_config_1_2 (0x3A): This command requires that the fan speed be commanded by duty cycle. Both fans must be commanded simultaneously. The tachometer pulses per revolution is not used. Default is duty cycle control.

Fan_command_1 (0x3B): This command instructs the rectifier to increase the speed of both fans. The transmitted data byte represents the hex equivalent of duty cycle in percentage, i.e. 100% = 0 x 64h. The command can only increase fan speed, it cannot instruct the rectifier to reduce the fan speed below what the rectifier requires for internal control. An incorrect value will result in a 'data error'.

Sending 00h tells the rectifier to revert back to its internal control.

Vout_OV_fault_limit (0x40): Sets the value at which the main output voltage will shut down. The default OV_fault value is set at 14.0Vdc. This level can be permanently changed and stored in non-volatile memory.

Vout_OV_fault_response (0x41): This is a 'read only' register. The only allowable state is a latched.

Vout_OV_warn_limit (0x42): Sets the value at which a warning will be issued that the output voltage is too high. The default OV_warn limit is set at 13.5Vdc. Exceeding the warning value will set the Alert# signal. This level can be permanently changed and stored in non-volatile memory.

Vout_UV_warn_limit (0x43): Sets the value at which a warning will be issued that the output voltage is too low. The default UV_warning limit is set at 10.8Vdc. Reduction below the warning value will set the Alert# signal. This level can be permanently changed and stored in non-volatile memory.

Vout_UV_fault_limit (0x44): Sets the value at which the rectifier will shut down if the output gets below this level. The default UV_fault limit is set at 10Vdc. This register is masked if the UV is caused by interruption of the input voltage to the rectifier. This level can be permanently changed and stored in non-volatile memory.

Vout_UV_fault_response (0x45): This is a 'read only' register. The only allowable state is restart.

Iout_OC_fault_limit (0x46): Sets the value at which the rectifier will shut down at High/Low Line. This level can be permanently changed and stored in non-volatile memory.

Iout_OC_fault_response (0x47): This is a 'read only' register. The only allowable state is restart.

Iout_OC_warn_limit (0x4A): Sets the value at which the rectifier issues a warning that the output current is getting too close to the shutdown level at high/low line. This level can be permanently changed and stored in non-volatile memory.

OT_fault_limit (0x4F): Sets the value at which the rectifier responds to an OT event, sensed by the hottest sensor. The response is defined by the OT_fault_response register.

OT_fault_response (0x50): Sets the response if the output overtemperature exceeds the OT_Fault_limit value. The default OT_fault_response is hiccup (0xC0). The only two allowable states are latched (0x80) or hiccup. The default response state can be permanently changed and stored in non-volatile memory.

OT_warn_limit (0x51): Sets the value at which the rectifier issues a warning when the hottest temperature sensor exceeds the warn limit.

Vin_OV_fault_limit (0x55): Sets the value at which the rectifier shuts down because the input voltage exceeds the allowable operational limit. The default Vin_OV_fault_limit is set at 76Vdc. This level can be permanently lowered and stored in non- volatile memory.

Vin_OV_fault_response (0x56): This is a 'read only' register. The only allowable state is restart.

Vin_OV_warn_limit (0x57): Sets the value at which a warning will be issued that the input voltage is too high. The default OV_warn_limit is 74Vdc. This level can be permanently changed and stored in non-volatile memory.

Vin_UV_warn_limit (0x58): This is another warning flag indicating that the input voltage is decreasing dangerously close to the low input voltage shutdown level. The default UV_fault_limit is 40Vdc. This level can be permanently raised, but not lowered, and stored in non-volatile memory.

Vin_UV_fault_limit (0x59): Sets the value at which the rectifier shuts down because the input voltage falls below the allowable operational limit. The default Vin_UV_fault_limit is set at 38Vdc. This level can be permanently raised and stored in non-volatile memory.

Vin_UV_fault_response (0x5A): This is a 'read only' register. The only allowable state is restart.

STATUS_BYTE (0x78): Returns one byte of information with a summary of the most critical device faults.

Bit Position	Flag	Default Value
7	Unit is busy	0
6	OUTPUT OFF	0
5	VOUT Overvoltage Fault	0
4	IOUT Overcurrent Fault	0
3	VIN Undervoltage Fault	0
2	Temperature Fault or Warning	0
1	CML (Comm. Memory Fault)	0
0	None of the above	0

TATUS_WORD (0x79): Returns status_byte as the low byte and the following high_byte.

Bit Position	Flag	Default Value
7	VOUT Fault or Warning	0
6	IOUT Fault or Warning	0
5	INPUT Fault or Warning	0
4	MFR SPECIFIC	0
3	POWER_GOOD# (is negated)	0
2	FAN Fault or Warning	0
1	OTHER	0
0	UNKNOWN Fault or Warning	0

STATUS_VOUT (0X7A): Returns one byte of information of output voltage related faults.

Bit Position	Flag	Default Value
7	VOUT OV Fault	0
6	VOUT_OV_WARNING	0
5	VOUT_UV_WARNING	0
4	VOUT UV Fault	0
3-0	X	0

STATUS_IOUT (0X7B): Returns one byte of information of output current related faults. The OC Fault limit sets where current limit is set. The rectifier shuts down below the LV fault limit setting.

Bit Position	Flag	Default Value
7	IOUT OC Fault	0
6	IOUT OC LV Fault	0
5	IOUT OC Warning	0
4	X	0
3	CURRENT SHARE Fault	0
2	IN POWER LIMITING MODE	0
1-0	X	0

STATUS_INPUT (0X7C): Returns one byte of information of input voltage related faults.

Bit Position	Flag	Default Value
7	VIN_OV_Fault	0
6	VIN_OV_Warning	0
5	VIN_UV_ Warning	0
4	VIN_UV_Fault	0
3	Unit OFF for low input voltage	0
2	IIN_OC_Fault	0
1-0	X	0

STATUS_TEMPERATURE (0x7D): Returns one byte of information of temperature related faults.

Bit Position	Flag	Default Value
7	OT Fault	0
6	OT Warning	0
5-0	X	0

STATUS_CML (0X7E): Returns one byte of information of communication related faults.

Bit Position	Flag	Default Value
7	Invalid/Unsupported Command	0
6	Invalid/Unsupported Data	0
5	Packet Error Check Failed	0
4-2	X	0
1	Other Communication Fault	0
0	X	0

STATUS_fans_1_2 (0X81): Returns one byte of information of fan status.

Bit Position	Flag	Default Value
7	Fan 1 fault	0
6	X	0
5-4	X	0
3-2	Fan 1 & 2 speed overwritten	0
1-0	X	0

Read back Descriptions

Single parameter read back: Functions can be read back one at a time using the read_word_protocol with PEC. A command is first sent out notifying the slave what function is to be read back followed by the data transfer.

Analog data is always transmitted LSB followed by MSB. A NA following the PEC byte signifies that the transmission is complete and is being terminated by the 'host'.

1	8	1	1	8	1
S	Slave address	Wr	A	Command Code	A

1	8	1	1
Sr	Slave address	Rd	A

8	1	8	1	8	1	1
LSB	A	MSB	A	PEC	No-Ack	P

Read back error: If the µC does not have sufficient time to retrieve the requested data, it has the option to return all FF's instead of incorrect data.

Read_fan_speed 1 (0x90): Reading the fan speed is in Linear Mode returning the RPM value of the fan.

Read_FRU_ID (0x99, 0x9A, 0x9B, 0x9E): Returns FRU information. Must be executed one register at a time.

1	8	1	1	8	1
S	Slave address	Wr	A	Command 0x9x	A

1	8	1	1	8	1
Sr	Slave address	Rd	A	Byte count = x	A

8	1	8	1	8	1	8	1	1
Byte_1	A	Byte	A	Byte_x	A	PEC	No-Ack	P

Mfr_ID (0x99): Manufacturer in ASCII – 6 characters maximum, General Electric – Critical Power represented as, GE-CP

Mfr_ID (0x9A): Manufacturer model-number in ASCII – 16 characters, for this unit: MPR0712DCxxxxxx

Mfr_revision (0x9B): Total 7 bytes, provides the product series number when the product was manufactured.

Mfr_serial (0x9E): Product serial number includes the manufacturing date, manufacturing location in up to 16 characters. For example:

13KZ51018193xxx, is decoded as;

13 – year of manufacture, 2013

KZ – manufacturing location, in this case Matamoros

51 – week of manufacture

018193xxx – serial #, mfr choice

Manufacturer-Specific PMBus® Commands

Many of the manufacturer-specific commands read back more than two bytes. If more than two bytes of data are returned, the standard SMBus® Block read is utilized. In this process, the Master issues a Write command followed by the data transfer from the rectifier. The first byte of the Block

Read data field sends back in hex format the number of data bytes, exclusive of the PEC number, that follows. Analog data is always transmitted LSB followed by MSB. A No-ack following the PEC byte signifies that the transmission is complete and is being terminated by the 'host'.

Read_firmware_rev [0xD5]: Reads back the firmware revision of all three µC in the rectifier.

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code 0xDD	A

1	1	7	1	1	8	1
A	Sr	Slave Address	Rd	A	Byte Count = 6	A

8	1	8	1
Primary major rev	A	Primary minor rev	A

8	1	8	1
Secondary major rev	A	Secondary minor rev	A

8	1	8	1	8	1	1
i2c major rev	A	i2c revision	A	PEC	No-ack	P

Read_run_timer [0xD6]: This command reads back the recorded operational ON state of the rectifier in hours. The operational ON state is accumulated from the time the rectifier is initially programmed at the factory. The rectifier is in the operational ON state both when in standby and when it delivers main output power. Recorded capacity is approximately 10 years of operational state.

1	7	1	1	8	1
S	Slave address	Wr	A	Command Code 0xDE	A

1	7	1	1	8	1
Sr	Slave Address	Rd	A	Byte count = 3	A

8	1	8	1	8	1
Time - LSB	A	Time	A	Time - MSB	A

8	1	1
PEC	No-ack	P

General performance descriptions

Default state: Rectifiers are programmed in the default state to automatically restart after a shutdown has occurred. The default state can be reconfigured by changing non-volatile memory (Store_user_code).

Restart after a latchoff: PMBus™ fault_response commands can be configured to direct the rectifier to remain latched off for over_voltage, over_temperature and over_current.

To restart after a latch off either of five restart mechanisms are available.

1. The hardware pin ON/OFF may be cycled OFF and then ON.

2. The unit may be commanded to restart via i2c through the Operation command by cycling the output OFF followed by ON.

3. Remove and reinsert the unit.

4. Turn OFF and then turn ON AC power to the unit.

5. Changing firmware from latch off to restart.

Each of these commands must keep the rectifier in the OFF state for at least 2 seconds, except for changing to restart.

Technical Specifications

A power system that is comprised of a number of rectifiers could have difficulty restarting after a shutdown event because of the non-synchronized behavior of the individual rectifiers. Implementing the   latch-off mechanism permits a synchronized restart that guarantees the simultaneous restart of the entire system.

A synchronous restart can be implemented by;

1. Issuing a GLOBAL OFF and then ON command to all rectifiers,

2. Toggling Off and then ON the ON/OFF (ENABLE) signal

3. Removing and reapplying input commercial power to the entire system.

The rectifiers should be turned OFF for at least 20 – 30 seconds in order to discharge all internal bias supplies and reset the soft start circuitry of the individual rectifiers.

Auto_restart: Auto-restart is the default configuration for over-current and over-temperature shutdowns. These features are configured by the PMBus® fault_response commands

Wiring diagram for output
CURRENT SHARING NOTS

Main current sharing is achieved using active current share method details.
Current sharing can be achieved with or without the remote sense (V_SENSE) connected to the common load.
+VSB outputs can be tied together for redundancy but total combined output power must not exceed the related standby power. The +VSB output has an internal ORING MOSFEET for additional redundancy/internal short protection.

The current sharing pin B5 is connected between sharing units (from an ISHARE bus). It is an input and/or an output (bi-directional analogue bus) as the voltage on the line controls the current share between sharing units. A power supply will respond to a change in this voltage but a power supply can also change the voltage depending on the load drawn from it. On a single unit, the voltage on the pin (and the common IHSARE bus would read 8.74VDC at 100% load. For two units sharing the same load this would read 4.37VDC for perfect current sharing (i.e. 50% load per unit).

The load for both the main 12V and VSB rails at the initial startup shall not be allowed to exceed the capability of a single unit. The load can be increased after a delay of 3sec (minimum), to allow all sharing units to achieve steady regulation.
