## Revision History

The following revision history table summarizes changes contained in this document. For your convenience, the page number designators have been linked to the appropriate location.

## Revision History

Date	Revision Level	Description	Page Number(s)
April, 2001	0.1	Label for pin 9 corrected in Figure 1-1 and Figure 1-2	19, 20
		\$FF is the erase state of the FLASH, not \$00.	82, 252, 255
		First bulleted paragraph under the subsection 15.5 Interrupts reworded for clarity	177
		Revision to the description of the CHxMAX bit and the note that follows that description	183
		Forced monitor mode information added to Table 16-1.	192
		In Figure 16-10. Monitor Data Format, resistor value for connection between VTST and IRQ1 changed from 10 kΩ to 1 kΩ.	194
February, 2002	1.0	7.2 Features — Corrected third bullet	71
		7.7.3 ICG Trim Register — Corrected description of the TRIM7:TRIM0 bits	97
		14.2 Features — Corrected divide by factors in first bullet	165
		Figure 14-1. Timebase Block Diagram — Corrected divide-by-2 blocks	166
		Table 14-1. Timebase Divider Selection — Corrected last divider tap entry	167
		Section 15. Timer Interface Module (TIM) — Timer discrepancies corrected throughout this section	169
		17.4 Thermal Characteristics — Corrected SOIC thermal resistance and maximum junction temperature	202
		17.5 5.0-Vdc DC Electrical Characteristics and — Corrected footnote for VDD supply current in stop mode	203 and 204
		Appendix B. MC68HC08KX8 — Added to supply exception information for the MC68HC08KX8	215
March, 2004	2.0	Reformatted to current publication standards	Throughout
		2.7 FLASH Page Erase Operation — Updated procedure	33
		2.8 FLASH Mass Erase Operation — Updated procedure	33
		2.9 FLASH Program/Read Operation — Updated procedure	34
		Figure 5-1. COP Block Diagram — Updated figure	53
		Table 6-1. Instruction Set Summary — Added WAIT instruction	69
		Section 7. Internal Clock Generator Module (ICG) — Updated with new information	71 through 98
		14.2 Features — Corrected values given in the first bullet	165
		Table 15-3. Mode, Edge, and Level Selection — Reworked for clarity	182
		17.11 Memory Characteristics — Updated table with new information	210
July, 2005	2.1	Updated to meet Freescale identity guidelines.	Throughout

## List of Chapters

# Table of Contents

## Chapter 1 General Description

1.1	Introduction	17
1.2	Features	17
1.3	MCU Block Diagram	18
1.4	Pin Assignments	20
1.4.1	Supply Pins ( $V_{DD}$ and $V_{SS}$ )	20
1.4.2	Oscillator Pins (OSC1 and OSC2)	21
1.4.3	External Interrupt Pin (IRQ1)	21
1.4.4	Port A Input/Output (I/O) Pins (PTA4/ $\overline{KBD4}$ –PTA0/ $\overline{KBD0}$ )	21
1.4.5	Analog Reference Pin ( $V_{REFH}$ )	21
1.4.6	Port B Input/Output (I/O) Pins (PTB7/(OSC2)/ $\overline{RST}$ –PTB0/AD0)	21

## Chapter 2 Memory

2.1	Introduction	23
2.2	I/O Registers	23
2.3	Monitor ROM	23
2.4	Random-Access Memory (RAM)	31
2.5	FLASH Memory (FLASH)	31
2.6	FLASH Control Register	31
2.7	FLASH Page Erase Operation	32
2.8	FLASH Mass Erase Operation	33
2.9	FLASH Program/Read Operation	34
2.10	FLASH Block Protection	36
2.11	FLASH Block Protect Register	36
2.12	Wait Mode	37
2.13	Stop Mode	37

## Chapter 3 Analog-to-Digital Converter (ADC)

3.1	Introduction	39
3.2	Features	39
3.3	Functional Description	39
3.3.1	ADC Port I/O Pins	39
3.3.2	Voltage Conversion	41
3.3.3	Conversion Time	41
3.3.4	Continuous Conversion	42
3.3.5	Accuracy and Precision	42

## Table of Contents

3.4	Interrupts	42
3.5	Low-Power Modes	42
3.5.1	Wait Mode	42
3.5.2	Stop Mode	42
3.6	I/O Signals	43
3.6.1	ADC Analog Power and ADC Voltage Reference Pins	43
3.6.2	ADC Voltage In (ADCVIN)	43
3.7	I/O Registers	43
3.7.1	ADC Status and Control Register	43
3.7.2	ADC Data Register	45
3.7.3	ADC Input Clock Register	45

### Chapter 4 Configuration Register (CONFIG)

4.1	Introduction	47
4.2	Functional Description	47

### Chapter 5 Computer Operating Properly Module (COP)

5.1	Introduction	51
5.2	Block Diagram	51
5.3	Functional Description	52
5.4	I/O Signals	52
5.4.1	CGMXCLK	52
5.4.2	STOP Instruction	52
5.4.3	COPCTL Write	52
5.4.4	Power-On Reset	52
5.4.5	Internal Reset	52
5.4.6	Reset Vector Fetch	53
5.4.7	COPD (COP Disable)	53
5.4.8	COPRS (COP Rate Select)	53
5.5	COP Control Register	53
5.6	Interrupts	53
5.7	Monitor Mode	53
5.8	Low-Power Modes	53
5.8.1	Wait Mode	53
5.8.2	Stop Mode	54

### Chapter 6 Central Processor Unit (CPU)

6.1	Introduction	55
6.2	Features	55
6.3	CPU Registers	55
6.3.1	Accumulator	56
6.3.2	Index Register	56
6.3.3	Stack Pointer	57

6.3.4	Program Counter . . . . .	57
6.3.5	Condition Code Register . . . . .	58
6.4	Arithmetic/Logic Unit (ALU) . . . . .	59
6.5	Low-Power Modes . . . . .	59
6.5.1	Wait Mode . . . . .	59
6.5.2	Stop Mode . . . . .	59
6.6	CPU During Break Interrupts . . . . .	59
6.7	Instruction Set Summary . . . . .	60
6.8	Opcode Map . . . . .	65

## Chapter 7 Internal Clock Generator Module (ICG)

7.1	Introduction . . . . .	67
7.2	Features . . . . .	67
7.3	Functional Description . . . . .	67
7.3.1	Clock Enable Circuit . . . . .	69
7.3.2	Internal Clock Generator . . . . .	69
7.3.2.1	Digitally Controlled Oscillator . . . . .	70
7.3.2.2	Modulo "N" Divider . . . . .	70
7.3.2.3	Frequency Comparator . . . . .	70
7.3.2.4	Digital Loop Filter . . . . .	71
7.3.3	External Clock Generator . . . . .	71
7.3.3.1	External Oscillator Amplifier . . . . .	71
7.3.3.2	External Clock Input Path . . . . .	72
7.3.4	Clock Monitor Circuit . . . . .	73
7.3.4.1	Clock Monitor Reference Generator . . . . .	73
7.3.4.2	Internal Clock Activity Detector . . . . .	75
7.3.4.3	External Clock Activity Detector . . . . .	75
7.3.5	Clock Selection Circuit . . . . .	76
7.3.5.1	Clock Selection Switches . . . . .	77
7.3.5.2	Clock Switching Circuit . . . . .	77
7.4	Usage Notes . . . . .	77
7.4.1	Switching Clock Sources . . . . .	78
7.4.2	Enabling the Clock Monitor . . . . .	78
7.4.3	Using Clock Monitor Interrupts . . . . .	79
7.4.4	Quantization Error in DCO Output . . . . .	80
7.4.4.1	Digitally Controlled Oscillator . . . . .	80
7.4.4.2	Binary Weighted Divider . . . . .	80
7.4.4.3	Variable-Delay Ring Oscillator . . . . .	81
7.4.4.4	Ring Oscillator Fine-Adjust Circuit . . . . .	81
7.4.5	Switching Internal Clock Frequencies . . . . .	81
7.4.6	Nominal Frequency Settling Time . . . . .	81
7.4.6.1	Settling To Within 15% . . . . .	82
7.4.6.2	Total Settling Time . . . . .	82
7.4.7	Trimming Frequency on the Internal Clock Generator . . . . .	83

## Table of Contents

7.5	Low-Power Modes . . . . .	83
7.5.1	Wait Mode . . . . .	83
7.5.2	Stop Mode . . . . .	84
7.6	CONFIG (or MOR) Register Options . . . . .	84
7.6.1	External Clock Enable (EXTCLKEN) . . . . .	84
7.6.2	External Crystal Enable (EXTXTALEN) . . . . .	84
7.6.3	Slow External Clock (EXTSLOW) . . . . .	85
7.6.4	Oscillator Enable In Stop (OSCENINSTOP) . . . . .	85
7.7	I/O Registers . . . . .	85
7.7.1	ICG Control Register . . . . .	87
7.7.2	ICG Multiplier Register . . . . .	88
7.7.3	ICG Trim Register . . . . .	89
7.7.4	ICG DCO Divider Register . . . . .	89
7.7.5	ICG DCO Stage Register . . . . .	89

## Chapter 8 External Interrupt (IRQ)

8.1	Introduction . . . . .	91
8.2	Features . . . . .	91
8.3	Functional Description . . . . .	91
8.4	IRQ1 Pin . . . . .	93
8.5	IRQ Status and Control Register . . . . .	94

## Chapter 9 Keyboard Interrupt Module (KBI)

9.1	Introduction . . . . .	95
9.2	Features . . . . .	95
9.3	Functional Description . . . . .	97
9.4	Keyboard Initialization . . . . .	98
9.5	Low-Power Modes . . . . .	98
9.5.1	Wait Mode . . . . .	98
9.5.2	Stop Mode . . . . .	98
9.6	I/O Registers . . . . .	99
9.6.1	Keyboard Status and Control Register . . . . .	99
9.6.2	Keyboard Interrupt Enable Register . . . . .	100

## Chapter 10 Low-Voltage Inhibit (LVI)

10.1	Introduction . . . . .	101
10.2	Features . . . . .	101
10.3	Functional Description . . . . .	101
10.3.1	Polled LVI Operation . . . . .	102
10.3.2	Forced Reset Operation . . . . .	102
10.3.3	Voltage Hysteresis Protection . . . . .	102
10.3.4	LVI Trip Selection . . . . .	102
10.4	LVI Status Register . . . . .	103

10.5	LVI Interrupts .....	103
10.6	Low-Power Modes .....	103
10.6.1	Wait Mode .....	103
10.6.2	Stop Mode .....	103

## Chapter 11 Input/Output (I/O) Ports (PORTS)

11.1	Introduction .....	105
11.2	Port A .....	106
11.2.1	Port A Data Register .....	106
11.2.2	Data Direction Register A .....	106
11.2.3	Port A Input Pullup Enable Register .....	107
11.3	Port B .....	108
11.3.1	Port B Data Register .....	108
11.3.2	Data Direction Register B .....	109

## Chapter 12 Serial Communications Interface Module (SCI)

12.1	Introduction .....	111
12.2	Features .....	111
12.3	Pin Name Conventions .....	113
12.4	Functional Description .....	113
12.4.1	Data Format .....	113
12.4.2	Transmitter .....	115
12.4.2.1	Character Length .....	115
12.4.2.2	Character Transmission .....	115
12.4.2.3	Break Characters .....	117
12.4.2.4	Idle Characters .....	117
12.4.2.5	Inversion of Transmitted Output .....	117
12.4.2.6	Transmitter Interrupts .....	117
12.4.3	Receiver .....	118
12.4.3.1	Character Length .....	119
12.4.3.2	Character Reception .....	119
12.4.3.3	Data Sampling .....	119
12.4.3.4	Framing Errors .....	121
12.4.3.5	Baud Rate Tolerance .....	121
12.4.3.6	Receiver Wakeup .....	123
12.4.3.7	Receiver Interrupts .....	123
12.4.3.8	Error Interrupts .....	123
12.5	Low-Power Modes .....	124
12.5.1	Wait Mode .....	124
12.5.2	Stop Mode .....	124
12.6	I/O Signals .....	124
12.6.1	TxD (Transmit Data) .....	124
12.6.2	RxD (Receive Data) .....	124

## Table of Contents

12.7	I/O Registers	125
12.7.1	SCI Control Register 1	125
12.7.2	SCI Control Register 2	127
12.7.3	SCI Control Register 3	129
12.7.4	SCI Status Register 1	130
12.7.5	SCI Status Register 2	132
12.7.6	SCI Data Register	133
12.7.7	SCI Baud Rate Register	133

## Chapter 13 System Integration Module (SIM)

13.1	Introduction	137
13.2	SIM Bus Clock Control and Generation	139
13.2.1	Bus Timing	139
13.2.2	Clock Startup from POR or LVI Reset	139
13.2.3	Clocks in Stop Mode and Wait Mode	139
13.3	Reset and System Initialization	140
13.3.1	Active Resets from Internal Sources	140
13.3.1.1	Power-On Reset	141
13.3.1.2	Computer Operating Properly (COP) Reset	141
13.3.1.3	Illegal Opcode Reset	141
13.3.1.4	Illegal Address Reset	142
13.3.1.5	Forced Monitor Mode Entry Reset (MENRST)	142
13.3.1.6	Low-Voltage Inhibit (LVI) Reset	142
13.4	SIM Counter	142
13.4.1	SIM Counter During Power-On Reset	142
13.4.2	SIM Counter During Stop Mode Recovery	142
13.4.3	SIM Counter and Reset States	142
13.5	Program Exception Control	143
13.5.1	Interrupts	143
13.5.1.1	Hardware Interrupts	144
13.5.1.2	SWI Instruction	145
13.5.2	Reset	145
13.6	Low-Power Modes	145
13.6.1	Wait Mode	146
13.6.2	Stop Mode	147
13.7	SIM Registers	148
13.7.1	SIM Reset Status Register	148
13.7.2	Interrupt Status Registers	149
13.7.2.1	Interrupt Status Register 1	149
13.7.2.2	Interrupt Status Register 2	150
13.7.2.3	Interrupt Status Register 3	150

## Chapter 14 Timebase Module (TBM)

14.1	Introduction	151
14.2	Features	151
14.3	Functional Description	151
14.4	Interrupts	151
14.5	TBM Interrupt Rate	153
14.6	Low-Power Modes	153
14.6.1	Wait Mode	153
14.6.2	Stop Mode	153
14.7	Timebase Control Register	154

## Chapter 15 Timer Interface Module (TIM)

15.1	Introduction	155
15.2	Features	155
15.3	Pin Name Conventions	155
15.4	Functional Description	155
15.4.1	TIM Counter Prescaler	158
15.4.2	Input Capture	158
15.4.3	Output Compare	158
15.4.4	Unbuffered Output Compare	159
15.4.5	Buffered Output Compare	159
15.4.6	Pulse-Width Modulation (PWM)	159
15.4.7	Unbuffered PWM Signal Generation	160
15.4.8	Buffered PWM Signal Generation	161
15.4.9	PWM Initialization	161
15.5	Interrupts	162
15.6	Low-Power Modes	162
15.6.1	Wait Mode	162
15.6.2	Stop Mode	162
15.7	I/O Signals	162
15.8	I/O Registers	163
15.8.1	TIM Status and Control Register	163
15.8.2	TIM Counter Registers	164
15.8.3	TIM Counter Modulo Registers	165
15.8.4	TIM Channel Status and Control Registers	165
15.8.5	TIM Channel Registers	168

## Chapter 16 Development Support

16.1	Introduction	169
16.2	Break Module (BRK)	169
16.2.1	Functional Description	169
16.2.1.1	Flag Protection During Break Interrupts	169
16.2.1.2	CPU During Break Interrupts	170

## Table of Contents

16.2.1.3	TIM1 and TIM2 During Break Interrupts	171
16.2.1.4	COP During Break Interrupts	171
16.2.2	Break Module Registers	171
16.2.2.1	Break Status and Control Register	171
16.2.2.2	Break Address Registers	172
16.2.2.3	Break Status Register	172
16.2.2.4	Break Flag Control Register	173
16.2.2.5	Break Auxiliary Register	173
16.2.3	Low-Power Modes	173
16.2.3.1	Wait Mode	173
16.2.3.2	Stop Mode	173
16.3	Monitor ROM (MON)	174
16.3.1	Functional Description	174
16.3.1.1	Monitor Mode Entry	174
16.3.1.2	Normal Monitor Mode	174
16.3.1.3	Forced Monitor Mode	176
16.3.1.4	Monitor Mode Vectors	176
16.3.1.5	Data Format	177
16.3.1.6	Break Signal	177
16.3.1.7	Baud Rate	177
16.3.1.8	Force Monitor Mode	177
16.3.1.9	Normal Monitor Mode	177
16.3.1.10	Commands	178
16.3.2	Security	181

## Chapter 17 Electrical Specifications

17.1	Introduction	183
17.2	Absolute Maximum Ratings	183
17.3	Functional Operating Range	184
17.4	Thermal Characteristics	184
17.5	5.0-Vdc DC Electrical Characteristics	185
17.6	3.0-Vdc DC Electrical Characteristics	186
17.7	Internal Oscillator Characteristics	187
17.8	External Oscillator Characteristics	187
17.9	Trimmed Accuracy of the Internal Clock Generator	188
17.9.1	2.7-Volt to 3.3-Volt Trimmed Internal Clock Generator Characteristics	188
17.9.2	4.5-Volt to 5.5-Volt Trimmed Internal Clock Generator Characteristics	188
17.10	Analog-to-Digital Converter (ADC) Characteristics	191
17.11	Memory Characteristics	192

## Chapter 18

### Ordering Information and Mechanical Specifications

18.1	Introduction	193
18.2	MC Order Numbers	193
18.3	16-Pin Plastic Dual In-Line Package (PDIP)	194
18.4	16-Pin Small Outline Package (SOIC)	194

#### Appendix A

##### MC68HC908KX2

A.1	Introduction	195
A.2	Functional Description	195

#### Appendix B

##### MC68HC08KX8

B.1	Introduction	197
B.2	FLASH x ROM Module Changes	197
B.2.1	FLASH for ROM Substitution	197
B.2.2	Partial Use of FLASH-Related Module	199
B.3	Configuration Register Programming	199
B.4	Electrical Specifications	201
B.4.1	Absolute Maximum Ratings	201
B.4.2	Functional Operating Range	202
B.4.3	Thermal Characteristics	202
B.4.4	5.0-Vdc DC Electrical Characteristics	203
B.4.5	3.0-Vdc DC Electrical Characteristics	204
B.4.6	Internal Oscillator Characteristics	205
B.4.7	External Oscillator Characteristics	205
B.4.8	Trimmed Accuracy of the Internal Clock Generator	206
B.4.8.1	2.7-Volt to 3.3-Volt Trimmed Internal Clock Generator Characteristics	206
B.4.8.2	4.5-Volt to 5.5-Volt Trimmed Internal Clock Generator Characteristics	206
B.4.9	Analog-to-Digital Converter (ADC) Characteristics	207
B.4.10	Memory Characteristics	207

# Chapter 1

## General Description

### 1.1 Introduction

The MC68HC908KX8 is a member of the low-cost, high-performance M68HC08 Family of 8-bit microcontroller units (MCU). The M68HC08 Family is based on the customer-specified integrated circuit (CSIC) design strategy. All MCUs in the family use the enhanced M68HC08 central processor unit (CPU08) and are available with a variety of modules, memory sizes and types, and package types.

The information contained in this document pertains to the MC68HC908KX2 and the MC68HC08KX8 with the exceptions found in:

- [Appendix A MC68HC908KX2](#)
- [Appendix B MC68HC08KX8](#)

### 1.2 Features

Features include:

- High-performance M68HC08 architecture
- Fully upward-compatible object code with M6805, M146805, and M68HC05 Families
- Maximum internal bus frequencies of:
  - 8 MHz at 5.0 V
  - 4 MHz at 3.0 V
- Internal oscillator requiring no external components:
  - Software selectable bus frequencies
  - 25 percent accuracy with trim capability to 2 percent
  - Clock monitor
  - Option to allow use of external clock source or external crystal/ceramic resonator
- Eight Kbytes of on-chip, in-circuit programmable FLASH memory
- FLASH program memory security<sup>(1)</sup>
- On-chip programming firmware for use with host personal computer which does not require high voltage for entry
- 192 bytes of on-chip random-access memory (RAM)
- 16-bit, 2-channel timer interface (TIM) module
- 4-channel, 8-bit, analog-to-digital converter (ADC) with high-voltage reference ( $V_{REFH}$ ) double bonded to  $V_{DD}$  pin

---

1. No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the FLASH difficult for unauthorized users.

## General Description

- Serial communications interface (SCI) module
- 5-bit keyboard interrupt (KBI) with wakeup feature
- 13 general-purpose input/output (I/O) ports:
  - Five shared with KBI and TIM, with 15-mA source/15-mA sink capabilities and with programmable pullups on general-purpose input ports
  - Four shared with ADC
  - Two shared with SCI
- Low-voltage inhibit (LVI) module with software selectable trip points, 2.6-V or 4.3-V trip point
- Timebase module (TBM) with
  - Clock prescaler for eight user-selectable, periodic real-time interrupts
  - Active clock source in stop mode for periodic wakeup from stop using external crystal or internal oscillator
- External asynchronous interrupt pin with internal pullup ( $\overline{\text{IRQ1}}$ )
- System protection features:
  - Computer operating properly (COP) reset
  - Low-voltage detection with reset
  - Illegal opcode detection with reset
  - Illegal address detection with reset
- 16-pin plastic dual in-line (PDIP) or small outline (SOIC) package
- Low-power design fully static with stop and wait modes
- Internal power-up reset circuit requiring no external pins
- $-40^{\circ}\text{C}$  to  $+125^{\circ}\text{C}$  operation

### Features of the CPU08 include:

- Enhanced HC05 programming model
- Extensive loop control functions
- 16 addressing modes, eight more than the M68HC05
- 16-bit index register and stack pointer
- Memory-to-memory data transfers
- Fast  $8 \times 8$  multiply instruction
- Fast 16/8 divide instruction
- Binary-coded decimal (BCD) instructions
- Optimization for controller applications
- Third party C language support

## 1.3 MCU Block Diagram

Figure 1-1 shows the structure of the MC68HC908KX8.

Notes:

1. Pin contains integrated pullup resistor
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.

Figure 1-1. MC68HC908KX8 MCU Block Diagram

## 1.4 Pin Assignments

Figure 1-2 shows the pin assignments for MC68HC908KX8.

Figure 1-2. PDIP and SOIC Pin Assignments

### 1.4.1 Supply Pins (V<sub>DD</sub> and V<sub>SS</sub>)

V<sub>DD</sub> and V<sub>SS</sub> are the power supply and ground pins. The MCU operates from a single power supply.

Fast signal transitions on MCU pins place high, short-duration current demands on the power supply. To prevent noise problems, take special care to provide power supply bypassing at the MCU as shown in Figure 1-3. Place the bypass capacitors as close to the MCU power pins as possible. Use high-frequency response ceramic capacitors for C<sub>Bypass</sub>. C<sub>Bulk</sub> are optional bulk current bypass capacitors for use in applications that require the port pins to source high-current levels.

Note: Component values shown represent typical applications.

Figure 1-3. Power Supply Bypassing

### 1.4.2 Oscillator Pins (OSC1 and OSC2)

The OSC1 and OSC2 pins are available through programming options in the configuration register. These pins then become the connections to an external clock source or crystal/ceramic resonator. PTB7 and PTB6 are not available for the crystal/ceramic resonator option and PTB6 is unavailable for the external clock source option.

### 1.4.3 External Interrupt Pin ( $\overline{\text{IRQ1}}$ )

$\overline{\text{IRQ1}}$  is an asynchronous external interrupt pin with an internal pullup resistor. See [Chapter 8 External Interrupt \(IRQ\)](#).

### 1.4.4 Port A Input/Output (I/O) Pins (PTA4/ $\overline{\text{KBD4}}$ –PTA0/ $\overline{\text{KBD0}}$ )

PTA4/ $\overline{\text{KBD4}}$ –PTA0/ $\overline{\text{KBD0}}$  is a 5-bit special-function port that shares its pins with the keyboard interrupt (KBI) module and the 2-channel timer module (TIM).

- Any or all of the port A pins can be programmed to serve as keyboard interrupt pins. The respective pin utilizes an internal pullup resistor when enabled. See [Chapter 9 Keyboard Interrupt Module \(KBI\)](#).
- Each port A pin contains a software selectable internal pullup resistor when the general-function I/O port is configured as an input. See [Chapter 11 Input/Output \(I/O\) Ports \(PORTS\)](#). The pullup resistor is automatically disabled once a TIM special function is enabled for that pin.
- All port A pins are high-current source/sink pins.

#### NOTE

*Any unused inputs and I/O ports should be tied to an appropriate logic level (either  $V_{DD}$  or  $V_{SS}$ ). Although the I/O ports of the MC68HC908KX8 do not require termination, termination is recommended to reduce the possibility of static damage.*

### 1.4.5 Analog Reference Pin ( $V_{\text{REFH}}$ )

The  $V_{\text{REFH}}$  pin is the analog reference voltage for the analog-to-digital converter (ADC) module. The voltage is supplied through a double-bond to the  $V_{DD}$  pin. See [Chapter 17 Electrical Specifications](#) for ADC parameters.

### 1.4.6 Port B Input/Output (I/O) Pins (PTB7/ $\overline{\text{OSC2}}$ / $\overline{\text{RST}}$ –PTB0/ $\overline{\text{AD0}}$ )

PTB7/ $\overline{\text{OSC2}}$ / $\overline{\text{RST}}$ –PTB0/ $\overline{\text{AD0}}$  are general-purpose bidirectional I/O port pins, all sharing special functions.

- PTB7 and PTB6 share with the on-chip oscillator circuit through configuration options. See [7.3.3 External Clock Generator](#).
- PTB5 and PTB4 share with the SCI module. See [Chapter 12 Serial Communications Interface Module \(SCI\)](#).
- PTB3–PTB0 share with the ADC module. See [Chapter 3 Analog-to-Digital Converter \(ADC\)](#).

# Chapter 2

## Memory

### 2.1 Introduction

The central processor unit (CPU08) can address 64 Kbytes of memory space.

The memory map, shown in [Figure 2-1](#), includes:

- 7680 bytes of FLASH memory
- 192 bytes of random-access memory (RAM)
- 36 bytes of user-defined vectors
- 295 bytes of monitor read-only memory (ROM)

### 2.2 I/O Registers

Most of the control, status, and data registers are in the zero-page area of \$0000–\$003F. Additional input/output (I/O) registers have the following addresses:

- \$FE01 — SIM reset status register, SRSR
- \$FE04 — Interrupt status register 1, INT1
- \$FE05 — Interrupt status register 2, INT2
- \$FE06 — Interrupt status register 3, INT3
- \$FE08 — FLASH control register, FLCR
- \$FE09 — Break address register high, BRKH
- \$FE0A — Break address register low, BRKL
- \$FE0B — Break status and control register, BRKSCR
- \$FE0C — LVI status register, LVISR
- \$FF7E — FLASH block protect register, FLBPR  
in non-volatile FLASH memory
- \$FFFF — COP control register, COPCTL

A summary of the available registers is provided in [Figure 2-2](#). [Table 2-1](#) is a list of vector locations.

### 2.3 Monitor ROM

The 295 bytes at addresses \$FE20–\$FF46 are reserved ROM addresses that contain the instructions for the monitor functions.

## 2.4 Random-Access Memory (RAM)

Addresses \$0040–\$00FF are RAM locations. The location of the stack RAM is programmable. The 16-bit stack pointer allows the stack to be anywhere in the 64-Kbyte memory space.

### NOTE

*For correct operation, the stack pointer must point only to RAM locations.*

Before processing an interrupt, the CPU uses five bytes of the stack to save the contents of the CPU registers.

### NOTE

*For M6805, M146805 and M68HC05 compatibility, the H register is not stacked.*

During a subroutine call, the CPU uses two bytes of the stack to store the return address. The stack pointer decrements during pushes and increments during pulls.

### NOTE

*Be careful when using nested subroutines. The CPU could overwrite data in the RAM during a subroutine or during the interrupt stacking operation.*

## 2.5 FLASH Memory (FLASH)

The FLASH memory is an array of 7,680 bytes with an additional 36 bytes of user vectors and one byte used for block protection.

### NOTE

*An erased bit reads as 1 and a programmed bit reads as 0.*

The program and erase operations are facilitated through control bits in the FLASH control register (FLCR). See [2.6 FLASH Control Register](#).

The FLASH is organized internally as an 8192-word by 8-bit complementary metal-oxide semiconductor (CMOS) page erase, byte (8-bit) program embedded FLASH memory. Each page consists of 64 bytes. The page erase operation erases all words within a page. A page is composed of two adjacent rows.

A security feature prevents viewing of the FLASH contents.<sup>(1)</sup>

## 2.6 FLASH Control Register

The FLASH control register (FLCR) controls FLASH program and erase operations.

Address: \$FE08

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	HVEN	MASS	ERASE	PGM
Write:								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

**Figure 2-3. FLASH Control Register (FLCR)**

1. No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the FLASH difficult for unauthorized users.

### HVEN — High-Voltage Enable Bit

This read/write bit enables the charge pump to drive high voltages for program and erase operations in the array. HVEN can be set only if either PGM = 1 or ERASE = 1 and the proper sequence for program or erase is followed.

- 1 = High voltage enabled to array and charge pump on
- 0 = High voltage disabled to array and charge pump off

### MASS — Mass Erase Control Bit

Setting this read/write bit configures the 8-Kbyte FLASH array for mass erase operation.

- 1 = MASS erase operation selected
- 0 = MASS erase operation unselected

### ERASE — Erase Control Bit

This read/write bit configures the memory for erase operation. ERASE is interlocked with the PGM bit such that both bits cannot be equal to 1 or set to 1 at the same time.

- 1 = Erase operation selected
- 0 = Erase operation unselected

### PGM — Program Control Bit

This read/write bit configures the memory for program operation. PGM is interlocked with the ERASE bit such that both bits cannot be equal to 1 or set to 1 at the same time.

- 1 = Program operation selected
- 0 = Program operation unselected

## 2.7 FLASH Page Erase Operation

Use this step-by-step procedure to erase a page (64 bytes) of FLASH memory to read as 1:

1. Set the ERASE bit and clear the MASS bit in the FLASH control register.
2. Read the FLASH block protect register.
3. Write any data to any FLASH location within the address range of the block to be erased.
4. Wait for a time,  $t_{NVS}$  (minimum 10  $\mu$ s).
5. Set the HVEN bit.
6. Wait for a time,  $t_{Erase}$  (minimum 1 ms or 4 ms).
7. Clear the ERASE bit.
8. Wait for a time,  $t_{NVH}$  (minimum 5  $\mu$ s).
9. Clear the HVEN bit.
10. After time,  $t_{RCV}$  (typical 1  $\mu$ s), the memory can be accessed in read mode again.

#### NOTE

*While these operations must be performed in the order shown, other unrelated operations may occur between the steps.*

In applications that require more than 1000 program/erase cycles, use the 4 ms page erase specification to get improved long-term reliability. Any application can use this 4 ms page erase specification. However, in applications where a FLASH location will be erased and reprogrammed less than 1000 times, and speed is important, use the 1 ms page erase specification to get a shorter cycle time.

## 2.8 FLASH Mass Erase Operation

Use the following procedure to erase the entire FLASH memory to read as a 1:

1. Set both the ERASE bit and the MASS bit in the FLASH control register.
2. Read the FLASH block protect register.
3. Write any data to any FLASH address<sup>(1)</sup> within the FLASH memory address range.
4. Wait for a time,  $t_{NVS}$  (minimum 10  $\mu$ s).
5. Set the HVEN bit.
6. Wait for a time,  $t_{MErase}$  (minimum 4 ms).
7. Clear the ERASE and MASS bits.

**NOTE**

*Mass erase is disabled whenever any block is protected (FLBPR does not equal \$FF).*

8. Wait for a time,  $t_{NVHL}$  (minimum 100  $\mu$ s).
9. Clear the HVEN bit.
10. After time,  $t_{RCV}$  (typical 1  $\mu$ s), the memory can be accessed in read mode again.

**NOTE**

*Programming and erasing of FLASH locations cannot be performed by code being executed from the FLASH memory. While these operations must be performed in the order shown, other unrelated operations may occur between the steps.*

---

1. When in monitor mode, with security sequence failed (see [16.3.2 Security](#)), write to the FLASH block protect register instead of any FLASH address.

## 2.9 FLASH Program/Read Operation

Programming of the FLASH memory is done on a row basis. A row consists of 32 consecutive bytes starting from addresses \$XX00, \$XX20, \$XX40, \$XX60, \$XX80, \$XXA0, \$XXC0, and \$XXE0. Use this step-by-step procedure to program a row of FLASH memory (Figure 2-4 is a flowchart representation).

### NOTE

*Only bytes which are currently \$FF may be programmed.*

1. Set the PGM bit. This configures the memory for program operation and enables the latching of address and data for programming.
2. Read the FLASH block protect register.
3. Write any data to any FLASH location within the address range desired.
4. Wait for a time,  $t_{NVS}$  (minimum 10  $\mu$ s).
5. Set the HVEN bit.
6. Wait for a time,  $t_{PGS}$  (minimum 5  $\mu$ s).
7. Write data to the FLASH address being programmed<sup>(1)</sup>.
8. Wait for time,  $t_{PROG}$  (minimum 30  $\mu$ s).
9. Repeat step 7 and 8 until all desired bytes within the row are programmed.
10. Clear the PGM bit<sup>(1)</sup>.
11. Wait for time,  $t_{NVH}$  (minimum 5  $\mu$ s).
12. Clear the HVEN bit.
13. After time,  $t_{RCV}$  (typical 1  $\mu$ s), the memory can be accessed in read mode again.

This program sequence is repeated throughout the memory until all data is programmed.

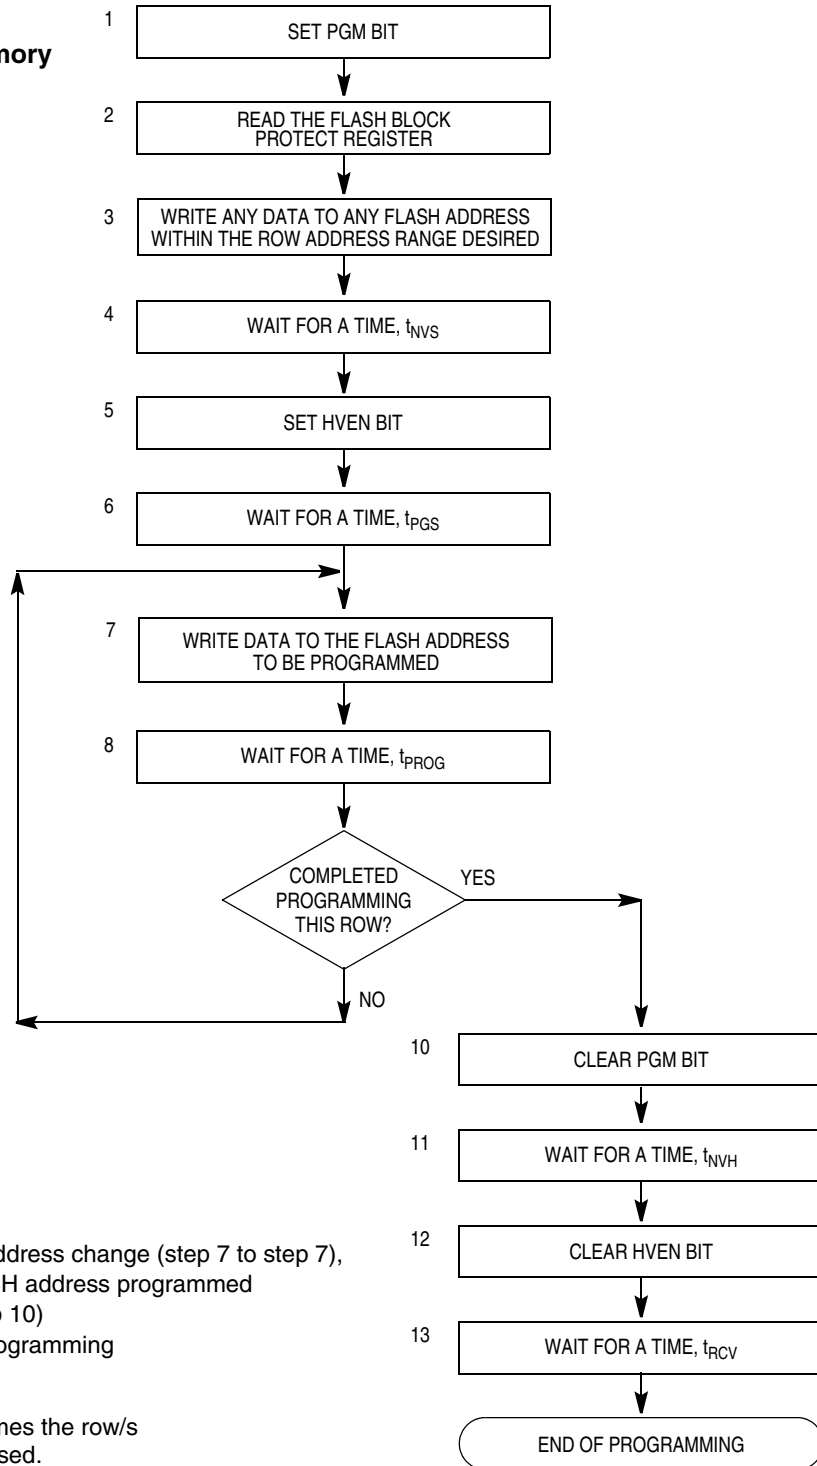

### NOTE

*Programming and erasing of FLASH locations cannot be performed by code being executed from the FLASH memory. While these operations must be performed in the order shown, other unrelated operations may occur between the steps. Do not exceed  $t_{PROG}$  maximum. See 17.11 [Memory Characteristics](#).*

---

1. The time between each FLASH address change, or the time between the last FLASH address programmed to clearing PGM bit, must not exceed the maximum programming time,  $t_{PROG}$  maximum.

**Algorithm for programming  
a row (32 bytes) of FLASH memory**

**Notes:**

The time between each FLASH address change (step 7 to step 7), or the time between the last FLASH address programmed to clearing PGM bit (step 7 to step 10) must not exceed the maximum programming time,  $t_{PROG}$  maximum.

This row program algorithm assumes the row/s to be programmed are initially erased.

**Figure 2-4. FLASH Programming Flowchart**

## 2.10 FLASH Block Protection

Due to the ability of the on-board charge pump to erase and program the FLASH memory in the target application, provision is made for protecting a block of memory from unintentional erase or program operations due to system malfunction. This protection is done by using the FLASH block protect register (FLBPR). The FLBPR determines the range of the FLASH memory which is to be protected. The range of the protected area starts from a location defined by FLBPR and ends at the bottom of the FLASH memory (\$FFFF). When the memory is protected, the HVEN bit cannot be set in either erase or program operations.

### NOTE

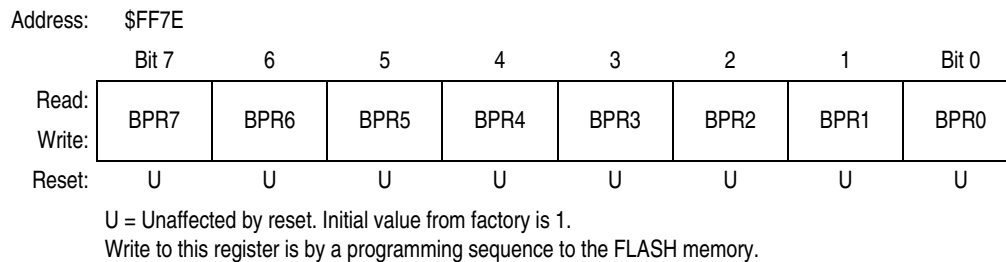

*In performing a program or erase operation, the FLASH block protect register must be read after setting the PGM or ERASE bit and before asserting the HVEN bit.*

When FLBPR is programmed with all 0s, the entire memory is protected from being programmed and erased. When all the bits are erased (all 1s), the entire memory is accessible for program and erase.

When bits within the FLBPR are programmed, they lock a block of memory address ranges as shown in [2.11 FLASH Block Protect Register](#). Once the FLBPR is programmed with a value other than \$FF, any erase or program of the FLBPR or the protected block of FLASH memory is prohibited. The FLBPR itself can be erased or programmed only with an external voltage,  $V_{TST}$ , present on the  $\overline{IRQ}$  pin. This voltage also allows entry from reset into the monitor mode.

## 2.11 FLASH Block Protect Register

The FLASH block protect register (FLBPR) is implemented as a byte within the FLASH memory, and therefore can be written only during a programming sequence of the FLASH memory. The value in this register determines the starting location of the protected range within the FLASH memory.

**Figure 2-5. FLASH Block Protect Register (FLBPR)**

### BPR7–BPR0 — FLASH Block Protect Bits

These eight bits represent bits 13–6 of a 16-bit memory address. Bits 15 and 14 are 1s and bits 5–0 are 0s.

The resultant 16-bit address is used for specifying the start address of the FLASH memory for block protection. The FLASH is protected from this start address to the end of FLASH memory, at \$FFFF. With this mechanism, the protect start address can be \$XX00, \$XX40, etc., (64 bytes page boundaries) within the FLASH memory. See [Figure 2-6](#) and [Table 2-2](#).

Figure 2-6. FLASH Block Protect Start Address

Table 2-2. Protect Start Address Examples

BPR7–BPR0	Start of Address of Protect Range <sup>(1)</sup>
\$80	The entire FLASH memory is protected.
\$81 (1000 0001)	\$E040 (1110 0000 0100 0000)
\$82 (1000 0010)	\$E080 (1110 0000 1000 0000)
and so on...	
\$FE (1111 1110)	\$FF80 (1111 1111 1000 0000)
\$FF	The entire FLASH memory is not protected.

1. The end address of the protected range is always \$FFFF.

## 2.12 Wait Mode

Putting the MCU into wait mode while the FLASH is in read mode does not affect the operation of the FLASH memory directly, but there will not be any memory activity since the CPU is inactive.

The WAIT instruction should not be executed while performing a program or erase operation on the FLASH, or the operation will discontinue and the FLASH will be on standby mode.

## 2.13 Stop Mode

Putting the MCU into stop mode while the FLASH is in read mode does not affect the operation of the FLASH memory directly, but there will not be any memory activity since the CPU is inactive.

The STOP instruction should not be executed while performing a program or erase operation on the FLASH, or the operation will discontinue and the FLASH will be on standby mode.

### NOTE

*Standby mode is the power-saving mode of the FLASH module in which all internal control signals to the FLASH are inactive and the current consumption of the FLASH is at a minimum.*

# Chapter 3

## Analog-to-Digital Converter (ADC)

### 3.1 Introduction

This section describes the 8-bit analog-to-digital converter (ADC).

### 3.2 Features

Features of the ADC module include:

- Four channels with multiplexed input
- Linear successive approximation
- 8-bit resolution
- Single or continuous conversion
- Conversion complete flag or conversion complete interrupt
- Selectable ADC clock

### 3.3 Functional Description

The ADC provides four pins for sampling external sources at pins PTB3–PTB0. An analog multiplexer allows the single ADC converter to select one of four ADC channels as ADC voltage in (ADCVIN). ADCVIN is converted by the successive approximation register-based counters. When the conversion is completed, ADC places the result in the ADC data register and sets a flag or generates an interrupt. See [Figure 3-2](#).

The MC68HC908KX8 uses  $V_{DD}$  as the high voltage reference.

#### 3.3.1 ADC Port I/O Pins

PTB3–PTB0 are general-purpose input/output (I/O) pins that are shared with the ADC channels.

The channel select bits define which ADC channel/port pin will be used as the input signal. The ADC overrides the port I/O logic by forcing that pin as input to the ADC. The remaining ADC channels/port pins are controlled by the port I/O logic and can be used as general-purpose I/O. Writes to the port register or DDR will not have any effect on the port pin that is selected by the ADC. Read of a port pin which is in use by the ADC will return a logic 0 if the corresponding DDR bit is at 0. If the DDR bit is at 1, the value in the port data latch is read.

## Notes:

1. Pin contains integrated pullup resistor
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.

Figure 3-1. Block Diagram Highlighting ADC Block and Pins

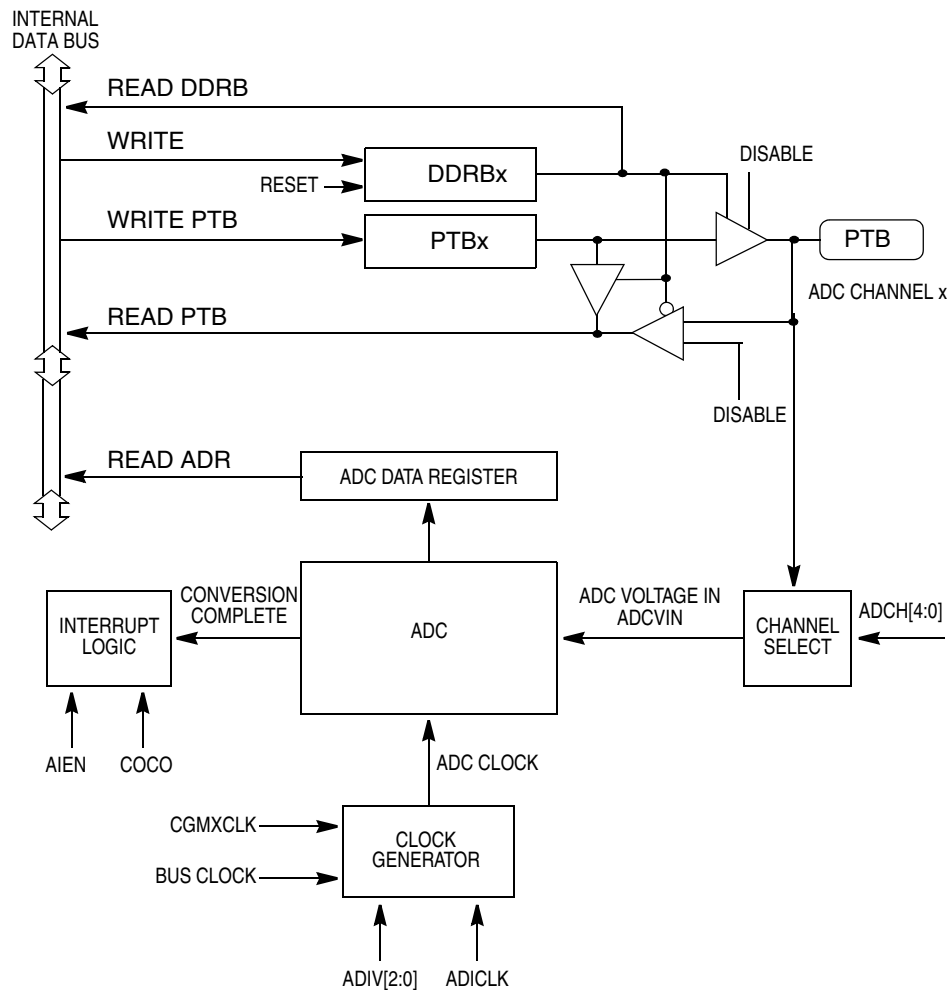

Figure 3-2. ADC Block Diagram

### 3.3.2 Voltage Conversion

When the input voltage to the ADC equals  $V_{REFH}$  (see [17.9 Trimmed Accuracy of the Internal Clock Generator](#)), the ADC converts the signal to \$FF (full scale). If the input voltage equals  $V_{SS}$ , the ADC converts it to \$00. Input voltages between  $V_{REFH}$  and  $V_{SS}$  are a straight-line linear conversion. All other input voltages will result in \$FF if greater than  $V_{REFH}$  and \$00 if less than  $V_{SS}$ .

#### NOTE

*Input voltage should not exceed the high-voltage reference, which in turn should not exceed supply voltages.*

### 3.3.3 Conversion Time

Conversion starts after a write to the ADSCR (ADC status control register, \$003C) and requires between 16 and 17 ADC clock cycles to complete. Conversion time in terms of the number of bus cycles is a function of CGMXCLK frequency, bus frequency, the ADIV prescaler bits, and the ADICLK bit. For example, with a CGMXCLK frequency of 8 MHz, bus frequency of 2 MHz, and fixed ADC clock frequency of 1 MHz, one conversion will take between 16 and 17  $\mu$ s and there will be 32 bus cycles between each conversion. Sample rate is approximately 60 kHz.

## Analog-to-Digital Converter (ADC)

Refer to [17.9 Trimmed Accuracy of the Internal Clock Generator](#).

$$\text{Conversion time} = \frac{16 \text{ to } 17 \text{ ADC clock cycles}}{\text{ADC clock frequency}}$$

$$\text{Number of bus cycles} = \text{conversion time} \times \text{bus frequency}$$

### 3.3.4 Continuous Conversion

In continuous conversion mode, the ADC data register will be filled with new data after each conversion. Data from the previous conversion will be overwritten whether that data has been read or not. Conversions will continue until the ADCO bit (ADC status control register, \$003C) is cleared. The COCO bit is set after the first conversion and will stay set until the next write of the ADC status and control register or the next read of the ADC data register.

### 3.3.5 Accuracy and Precision

The conversion process is monotonic and has no missing codes. See [17.9 Trimmed Accuracy of the Internal Clock Generator](#) for accuracy information.

## 3.4 Interrupts

When the AIEN bit is set, the ADC module is capable of generating a CPU interrupt after each ADC conversion. A CPU interrupt is generated if the COCO bit (ADC status control register, \$003C) is at 0. If the COCO bit is set, a direct-memory access (DMA) interrupt is generated.

#### **NOTE**

*Because the MC68HC908KX8 does not have a DMA module, the COCO bit should not be set while interrupts are enabled (AIEN = 1).*

The COCO bit is not used as a conversion complete flag when interrupts are enabled.

## 3.5 Low-Power Modes

The following subsections describe the low-power modes.

### 3.5.1 Wait Mode

The ADC continues normal operation during wait mode. Any enabled CPU interrupt request from the ADC can bring the MCU out of wait mode. If the ADC is not required to bring the MCU out of wait mode, power down the ADC by setting the ADCH[4:0] bits in the ADC status and control register before executing the WAIT instruction.

### 3.5.2 Stop Mode

The ADC module is inactive after the execution of a STOP instruction. Any pending conversion is aborted. ADC conversions resume when the MCU exits stop mode. Allow one conversion cycle to stabilize the analog circuitry before attempting a new ADC conversion after exiting stop mode.

## 3.6 I/O Signals

The ADC module has four channels that are shared with port B pins. Refer to [17.9 Trimmed Accuracy of the Internal Clock Generator](#) for voltages referenced here.

### 3.6.1 ADC Analog Power and ADC Voltage Reference Pins

The ADC analog portion uses  $V_{DD}$  as its power pin and  $V_{SS}$  as its ground pin.

Due to pin limitations, the  $V_{REFL}$  signal is internally connected to  $V_{SS}$  on the MC68HC908KX8. On the MC68HC908KX8, the  $V_{REFH}$  signal is internally connected to  $V_{DD}$ .

### 3.6.2 ADC Voltage In (ADCVIN)

ADCVIN is the input voltage signal from one of the four ADC channels to the ADC module.

## 3.7 I/O Registers

These I/O registers control and monitor ADC operation:

- ADC status and control register, ADSCR
- ADC data register, ADR
- ADC clock register, ADICLK

### 3.7.1 ADC Status and Control Register

The following paragraphs describe the function of the ADC status and control register (ADSCR).

Address:	\$003C							
	Bit 7	6	5	4	3	2	1	Bit 0
Read:	COCO	AIEN	ADCO	ADCH4	ADCH3	ADCH2	ADCH1	ADCH0
Write:	R							
Reset:	0	0	0	1	1	1	1	1
	R	= Reserved						

**Figure 3-3. ADC Status and Control Register (ADSCR)**

#### COCO — Conversions Complete Bit

When the AIEN bit is a 0, the COCO is a read-only bit which is set each time a conversion is completed. This bit is cleared whenever the ADC status and control register is written or whenever the ADC data register is read.

When the AIEN bit is a 1, the ADC module is capable of generating a CPU interrupt after each ADC conversion. A CPU interrupt is generated if the COCO bit (ADC status control register, \$003C) is at 0. If the COCO bit is at 1, a DMA interrupt is generated. Reset clears this bit.

- 1 = Conversion completed (AIEN = 0)
- 0 = Conversion not completed (AIEN = 0)  
or CPU interrupts enabled (AIEN = 1)

#### NOTE

*Because the MC68HC908KX8 does not have a DMA module, the COCO bit should not be set while interrupts are enabled (AIEN = 1).*

## Analog-to-Digital Converter (ADC)

### AIEN — ADC Interrupt Enable Bit

When this bit is set, an interrupt is generated at the end of an ADC conversion. The interrupt signal is cleared when the ADR register is read or the ADSCR register is written. Reset clears the AIEN bit.

- 1 = ADC interrupt enabled
- 0 = ADC interrupt disabled

### ADCO — ADC Continuous Conversion Bit

When set, the ADC will convert samples continuously and update the ADR register at the end of each conversion. Only one conversion is allowed when this bit is cleared. Reset clears the ADCO bit.

- 1 = Continuous ADC conversion
- 0 = One ADC conversion

### ADCH4–ADCH0 — ADC Channel Select Bits

ADCH4–ADCH0 form a 5-bit field which is used to select the input for the A/D measurement. The choices are one of four ADC channels, as well as  $V_{REFH}$  and  $V_{SS}$ . Input selection is detailed in [Table 3-1](#). Care should be taken when using a port pin as both an analog and a digital input simultaneously to prevent switching noise from corrupting the analog signal.

The ADC subsystem is turned off when the channel select bits are all set to 1. This feature allows for reduced power consumption for the MCU when the ADC is not used. Reset sets these bits.

#### NOTE

*Recovery from the disabled state requires one conversion cycle to stabilize.*

**Table 3-1. Mux Channel Select**

ADCH4	ADCH3	ADCH2	ADCH1	ADCH0	Input Select
0	0	0	0	0	PTB0
0	0	0	0	1	PTB1
0	0	0	1	0	PTB2
0	0	0	1	1	PTB3
0	0	1	0	0	Unused <sup>(1)</sup>
—	—	—	—	—	—
1	1	1	0	0	Unused <sup>(1)</sup>
1	1	1	0	1	$V_{REFH}$ <sup>(2)</sup>
1	1	1	1	0	$V_{SSAD}$ <sup>(2)</sup>
1	1	1	1	1	ADC power off

1. If any unused channels are selected, the resulting ADC conversion will be unknown.
2. The voltage levels supplied from internal reference nodes as specified in the table are used to verify the operation of the ADC converter both in production test and for user applications.

### 3.7.2 ADC Data Register

One 8-bit result register is provided. This register is updated each time an ADC conversion completes.

Address: \$003D

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	AD7	AD6	AD5	AD4	AD3	AD2	AD1	AD0
Write:	R	R	R	R	R	R	R	R
Reset:	Indeterminate after reset							

R = Reserved

**Figure 3-4. ADC Data Register (ADR)**

### 3.7.3 ADC Input Clock Register

This register selects the clock frequency for the ADC.

Address: \$003E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	ADIV2	ADIV1	ADIV0	ADICLK	0	0	0	R
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented      R = Reserved

**Figure 3-5. ADC Input Clock Register (ADICLK)**

#### ADIV2–ADIV0 — ADC Clock Prescaler Bits

ADIV2, ADIV1, and ADIV0 form a 3-bit field which selects the divide ratio used by the ADC to generate the internal ADC clock. [Table 3-2](#) shows the available clock configurations. The ADC clock should be set to approximately 1 MHz.

**Table 3-2. ADC Clock Divide Ratio**

ADIV2	ADIV1	ADIV0	ADC Clock Rate
0	0	0	ADC input clock ÷ 1
0	0	1	ADC input clock ÷ 2
0	1	0	ADC input clock ÷ 4
0	1	1	ADC input clock ÷ 8
1	X	X	ADC input clock ÷ 16

X = don't care

#### ADICLK — ADC Input Clock Select Bit

ADICLK selects either bus clock or the oscillator output clock (CGMXCLK) as the input clock source to generate the internal ADC rate clock. Reset selects CGMXCLK as the ADC clock source.

1 = Internal bus clock

0 = Oscillator output clock (CGMXCLK)

## Analog-to-Digital Converter (ADC)

The ADC requires a clock rate of approximately 1 MHz for correct operation. If the selected clock source is not fast enough, the ADC will generate incorrect conversions. See [17.9 Trimmed Accuracy of the Internal Clock Generator](#).

$$f_{\text{ADIC}} = \frac{f_{\text{CGMXCLK}} \text{ or bus frequency}}{\text{ADIV}[2:0]} \cong 1 \text{ MHz}$$

### **NOTE**

*During the conversion process, changing the ADC clock will result in an incorrect conversion.*

# Chapter 4

## Configuration Register (CONFIG)

### 4.1 Introduction

This section describes the configuration registers, CONFIG1 and CONFIG2. The configuration registers control these options:

- Stop mode recovery time, 32 CGMXCLK cycles or 4096 CGMXCLK cycles
- Computer operating properly (COP) timeout period,  $2^{18}$ – $2^4$  or  $2^{13}$ – $2^4$  CGMXCLK cycles
- STOP instruction
- Computer operating properly (COP) module
- Low-voltage inhibit (LVI) module control and voltage trip point selection
- Enable/disable the oscillator (OSC) during stop mode
- Serial communications interface (SCI) clock source selection
- External clock/crystal source control
- Enable/disable for the FLASH charge-pump regulator

### 4.2 Functional Description

The configuration registers are used in the initialization of various options and can be written once after each reset. All of the configuration register bits are cleared during reset. Since the various options affect the operation of the microcontroller unit (MCU), it is recommended that these registers be written immediately after reset. The configuration registers are located at \$001E and \$001F. For compatibility, a write to a read-only memory (ROM) version of the MCU at this location will have no effect. The configuration register may be read at anytime.

**NOTE**

*The CONFIG module is known as an MOR (mask option register) on a ROM device. On a ROM device, the options are fixed at the time of device fabrication and are neither writable nor changeable by the user.*

*On a FLASH device, the CONFIG registers are special registers containing one-time writable latches after each reset. Upon a reset, the CONFIG registers default to predetermined settings as shown in [Figure 4-1](#) and [Figure 4-2](#).*

**Figure 4-1. Configuration Register 2 (CONFIG2)**

## Configuration Register (CONFIG)

Address: \$001F

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	COPRS	LVISTOP	LVIRSTD	LVIPWRD	LVI5OR3 <sup>(1)</sup>	SSREC	STOP	COPD
Write:								
Reset:	0	0	0	0	0	0	0	0
Other Resets:	0	0	0	0	U	0	0	0

1. The LVI5OR3 bit is cleared only by a power-on reset (POR).  
U = Unaffected

**Figure 4-2. Configuration Register 1 (CONFIG1)**

### EXTCLKEN — External Clock Enable Bit

EXTCLKEN enables an external clock source or crystal/ceramic resonator to be used as a clock input. Setting this bit enables PTB6/(OSC1) pin to be a clock input pin. Clearing this bit (default setting) allows the PTB6/(OSC1) and PTB7/(OSC2)/RST pins to function as a general-purpose input/output (I/O) pin. Refer to [Table 4-1](#) for configuration options for the external source. See [Chapter 7 Internal Clock Generator Module \(ICG\)](#) for a more detailed description of the external clock operation.

1 = Allows PTB6/(OSC1) to be an external clock connection

0 = PTB6/(OSC1) and PTB7/(OSC2)/RST function as I/O port pins (default).

**Table 4-1. External Clock Option Settings**

External Clock Configuration Bits		Pin Function		Description
EXTCLKEN	EXTXTALEN	PTB6/(OSC1)	PTB7/(OSC2)/RST	
0	0	PTB6	PTB7	Default setting — external oscillator disabled
0	1	PTB6	PTB7	External oscillator disabled since EXTCLKEN not set
1	0	OSC1	PTB7	External oscillator configured for an external clock source input (square wave) on OSC1
1	1	OSC1	OSC2	External oscillator configured for an external crystal configuration on OSC1 and OSC2. System will also operate with square-wave clock source in OSC1.

### EXTSLOW — Slow External Crystal Enable Bit

The EXTSLOW bit has two functions. It configures the ICG module for a fast (1 MHz to 8 MHz) or slow (30 kHz to 100 kHz) speed crystal. The option also configures the clock monitor operation in the ICG module to expect an external frequency higher (307.2 kHz to 32 MHz) or lower (60 Hz to 307.2 kHz) than the base frequency of the internal oscillator. See [Chapter 7 Internal Clock Generator Module \(ICG\)](#).

1 = ICG set for slow external crystal operation

0 = ICG set for fast external crystal operation

### EXTXTALEN — External Crystal Enable Bit

EXTXTALEN enables the external oscillator circuits to be configured for a crystal configuration where the PTB6/(OSC1) and PTB7/(OSC2)/RST pins are the connections for an external crystal.

**NOTE**

*This bit does not function without setting the EXTCLKEN bit also.*

Clearing the EXTXTALEN bit (default setting) allows the PTB7/(OSC2)/ $\overline{\text{RST}}$  pin to function as a general-purpose I/O pin. Refer to [Table 4-1](#) for configuration options for the external source. See [Chapter 7 Internal Clock Generator Module \(ICG\)](#) for a more detailed description of the external clock operation.

EXTXTALEN, when set, also configures the clock monitor to expect an external clock source in the valid range of crystals (30 kHz to 100 kHz or 1 MHz to 8 MHz). When EXTXTALEN is clear, the clock monitor will expect an external clock source in the valid range for externally generated clocks when using the clock monitor (60 Hz to 32 MHz).

EXTXTALEN, when set, also configures the external clock stabilization divider in the clock monitor for a 4096-cycle timeout to allow the proper stabilization time for a crystal. When EXTXTALEN is clear, the stabilization divider is configured to 16 cycles since an external clock source does not need a startup time.

- 1 = Allows PTB7/(OSC2)/ $\overline{\text{RST}}$  to be an external crystal connection.
- 0 = PTB7/(OSC2)/ $\overline{\text{RST}}$  functions as an I/O port pin (default).

#### OSCENINSTOP — Oscillator Enable In Stop Mode Bit

OSCENINSTOP, when set, will enable the internal clock generator module to continue to generate clocks (either internal, ICLK, or external, ECLK) in stop mode. See [Chapter 7 Internal Clock Generator Module \(ICG\)](#). This function is used to keep the timebase running while the rest of the microcontroller stops. See [Chapter 14 Timebase Module \(TBM\)](#). When clear, all clock generation will cease and both ICLK and ECLK will be forced low during stop mode. The default state for this option is clear, disabling the ICG in stop mode.

- 1 = Oscillator enabled to operate during stop mode
- 0 = Oscillator disabled during stop mode (default)

#### NOTE

*This bit has the same functionality as the OSCSTOPENB CONFIG bit in MC68HC908GP20 and MC68HC908GR8 parts.*

#### SCIBDSRC — SCI Baud Rate Clock Source Bit

SCIBDSRC controls the clock source used for the SCI. The setting of this bit affects the frequency at which the SCI operates.

- 1 = Internal data bus clock is used as clock source for SCI.
- 0 = CGMXCLK is used as clock source for SCI.

#### COPRS — COP Rate Select Bit

COPD selects the COP timeout period. Reset clears COPRS. See [Chapter 5 Computer Operating Properly Module \(COP\)](#).

- 1 = COP timeout period =  $2^{13} - 2^4$  CGMXCLK cycles
- 0 = COP timeout period =  $2^{18} - 2^4$  CGMXCLK cycles

#### LVISTOP — LVI Enable in Stop Mode Bit

When the LVIPWRD bit is clear, setting the LVISTOP bit enables the LVI to operate during stop mode. Reset clears LVISTOP.

- 1 = LVI enabled during stop mode
- 0 = LVI disabled during stop mode

#### LVIRSTD — LVI Reset Disable Bit

LVIRSTD disables the reset signal from the LVI module. See [Chapter 10 Low-Voltage Inhibit \(LVI\)](#).

- 1 = LVI module resets disabled
- 0 = LVI module resets enabled

## Configuration Register (CONFIG)

### LVIPWRD — LVI Power Disable Bit

LVIPWRD disables the LVI module. See [Chapter 10 Low-Voltage Inhibit \(LVI\)](#).

- 1 = LVI module power disabled
- 0 = LVI module power enabled

### LVI5OR3 — LVI 5-V or 3-V Operating Mode Bit

LVI5OR3 selects the voltage operating mode of the LVI module (see [Chapter 10 Low-Voltage Inhibit \(LVI\)](#)). The voltage mode selected for the LVI should match the operating  $V_{DD}$ . See [Chapter 17 Electrical Specifications](#) for the LVI's voltage trip points for each of the modes.

- 1 = LVI operates in 5-V mode.
- 0 = LVI operates in 3-V mode.

#### **NOTE**

*The LVI5OR3 bit is cleared by a power-on reset (POR) only. Other resets will leave this bit unaffected.*

### SSREC — Short Stop Recovery Bit

SSREC enables the CPU to exit stop mode with a delay of 32 CGMXCLK cycles instead of a 4096-CGMXCLK cycle delay.

- 1 = Stop mode recovery after 32 CGMXCLK cycles
- 0 = Stop mode recovery after 4096 CGMXCLK cycles

#### **NOTE**

*Exiting stop mode by an LVI reset will result in the long stop recovery.*

If the system clock source selected is the internal oscillator or the external crystal and the OSCENINSTOP configuration bit is not set, the oscillator will be disabled during stop mode. The short stop recovery does not provide enough time for oscillator stabilization and thus the SSREC bit should not be set.

When using the LVI during normal operation but disabling during stop mode, the LVI will have an enable time of  $t_{EN}$ . The system stabilization time for power-on reset and long stop recovery (both 4096 CGMXCLK cycles) gives a delay longer than the LVI enable time for these startup scenarios. There is no period where the MCU is not protected from a low-power condition. However, when using the short stop recovery configuration option, the 32-CGMXCLK delay must be greater than the LVI's turn on time to avoid a period in startup where the LVI is not protecting the MCU.

### STOP — STOP Instruction Enable Bit

STOP enables the STOP instruction.

- 1 = STOP instruction enabled
- 0 = STOP instruction treated as illegal opcode

### COPD — COP Disable Bit

COPD disables the COP module. See [Chapter 5 Computer Operating Properly Module \(COP\)](#).

- 1 = COP module disabled
- 0 = COP module enabled

# Chapter 5

## Computer Operating Properly Module (COP)

### 5.1 Introduction

The computer operating properly (COP) module contains a free-running counter that generates a reset if allowed to overflow. The COP module helps software to recover from a runaway code. Periodically clearing the COP counter will prevent a COP reset from occurring. The COP module can be disabled through the COPD bit in the configuration (CONFIG) register.

### 5.2 Block Diagram

Figure 5-1. COP Block Diagram

## 5.3 Functional Description

The COP counter is a free-running 6-bit counter preceded by a 12-bit prescaler. If not cleared by software, the COP counter overflows and generates an asynchronous reset after  $2^{13}-2^4$  or  $2^{18}-2^4$  CGMXCLK cycles, depending on the state of the COP rate select bit, COPRS, in the configuration register. With a  $2^{18}-2^4$  CGMXCLK cycle overflow option, a 4.9152-MHz CGMXCLK frequency gives a COP timeout period of 53.3 ms. Writing any value to location \$FFFF before an overflow occurs prevents a COP reset by clearing the COP counter and stages 5–12 of the prescaler.

### NOTE

*Service the COP immediately after reset and before entering or after exiting stop mode to guarantee the maximum time before the first COP counter overflow.*

A COP reset pulls an internal reset for 64 CGMXCLK cycles and sets the COP bit in the system integration module (SIM) reset status register (SRSR).

In monitor mode, the COP is disabled if the  $\overline{\text{IRQ1}}$  pin is held at  $V_{\text{TST}}$ .

### NOTE

*Place COP clearing instructions in the main program and not in an interrupt subroutine. Such an interrupt subroutine could keep the COP from generating a reset even while the main program is not working properly.*

## 5.4 I/O Signals

The following paragraphs describe the signals shown in [Figure 5-1](#).

### 5.4.1 CGMXCLK

CGMXCLK is the internal clock generator (ICG) module's oscillator output signal. CGMXCLK is selected from either the internal clock source or the external crystal.

### 5.4.2 STOP Instruction

The STOP instruction clears the COP prescaler.

### 5.4.3 COPCTL Write

Writing any value to the COP control register (COPCTL) clears the COP counter and clears stages 12–5 of the COP prescaler. Reading the COP control register returns the low byte of the reset vector.

### 5.4.4 Power-On Reset

The power-on reset (POR) circuit clears the COP prescaler 4096 CGMXCLK cycles after power-up.

### 5.4.5 Internal Reset

An internal reset clears the COP prescaler and the COP counter.

### 5.4.6 Reset Vector Fetch

A reset vector fetch occurs when the vector address appears on the data bus. A reset vector fetch clears the COP prescaler.

### 5.4.7 COPD (COP Disable)

The COPD signal reflects the state of the COP disable bit (COPD) in the configuration register. See [Chapter 4 Configuration Register \(CONFIG\)](#).

### 5.4.8 COPRS (COP Rate Select)

The COPRS signal reflects the state of the COP rate select bit (COPRS) in the configuration register. See [Chapter 4 Configuration Register \(CONFIG\)](#).

## 5.5 COP Control Register

The COP control register (COPCTL) is located at address \$FFFF and overlaps the reset vector. Writing any value to \$FFFF clears the COP counter and stages 12–5 of the COP prescaler and starts a new timeout period. Reading location \$FFFF returns the low byte of the reset vector.

**Figure 5-2. COP Control Register (COPCTL)**

## 5.6 Interrupts

The COP does not generate CPU interrupt requests.

## 5.7 Monitor Mode

The COP is disabled in monitor mode when  $V_{TST}$  is present on the  $\overline{IRQ1}$  pin.

## 5.8 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

### 5.8.1 Wait Mode

The COP remains active in wait mode. To prevent a COP reset during wait mode, periodically clear the COP counter in a CPU interrupt routine.

## 5.8.2 Stop Mode

Stop mode holds the 12-bit prescaler counter in reset until after stop mode is exited. Service the COP immediately before entering or after exiting stop mode to ensure a full COP timeout period after entering or exiting stop mode.

To prevent inadvertently turning off the COP with a STOP instruction, a configuration option is available that disables the STOP instruction. When the STOP bit in the configuration has the STOP instruction disabled, execution of a STOP instruction results in an illegal opcode reset.

---

# Chapter 6

## Central Processor Unit (CPU)

### 6.1 Introduction

The M68HC08 CPU (central processor unit) is an enhanced and fully object-code-compatible version of the M68HC05 CPU. The *CPU08 Reference Manual* (document order number CPU08RM/AD) contains a description of the CPU instruction set, addressing modes, and architecture.

### 6.2 Features

Features of the CPU include:

- Object code fully upward-compatible with M68HC05 Family
- 16-bit stack pointer with stack manipulation instructions
- 16-bit index register with x-register manipulation instructions
- 8-MHz CPU internal bus frequency
- 64-Kbyte program/data memory space
- 16 addressing modes
- Memory-to-memory data moves without using accumulator
- Fast 8-bit by 8-bit multiply and 16-bit by 8-bit divide instructions
- Enhanced binary-coded decimal (BCD) data handling
- Modular architecture with expandable internal bus definition for extension of addressing range beyond 64 Kbytes
- Low-power stop and wait modes

### 6.3 CPU Registers

Figure 6-1 shows the five CPU registers. CPU registers are not part of the memory map.

## Central Processor Unit (CPU)

**Figure 6-1. CPU Registers**

### 6.3.1 Accumulator

The accumulator is a general-purpose 8-bit register. The CPU uses the accumulator to hold operands and the results of arithmetic/logic operations.

**Figure 6-2. Accumulator (A)**

### 6.3.2 Index Register

The 16-bit index register allows indexed addressing of a 64-Kbyte memory space. H is the upper byte of the index register, and X is the lower byte. H:X is the concatenated 16-bit index register.

In the indexed addressing modes, the CPU uses the contents of the index register to determine the conditional address of the operand.

The index register can serve also as a temporary data storage location.

**Figure 6-3. Index Register (H:X)**

### 6.3.3 Stack Pointer

The stack pointer is a 16-bit register that contains the address of the next location on the stack. During a reset, the stack pointer is preset to \$00FF. The reset stack pointer (RSP) instruction sets the least significant byte to \$FF and does not affect the most significant byte. The stack pointer decrements as data is pushed onto the stack and increments as data is pulled from the stack.

In the stack pointer 8-bit offset and 16-bit offset addressing modes, the stack pointer can function as an index register to access data on the stack. The CPU uses the contents of the stack pointer to determine the conditional address of the operand.

**Figure 6-4. Stack Pointer (SP)**

#### NOTE

*The location of the stack is arbitrary and may be relocated anywhere in random-access memory (RAM). Moving the SP out of page 0 (\$0000 to \$00FF) frees direct address (page 0) space. For correct operation, the stack pointer must point only to RAM locations.*

### 6.3.4 Program Counter

The program counter is a 16-bit register that contains the address of the next instruction or operand to be fetched.

Normally, the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

During reset, the program counter is loaded with the reset vector address located at \$FFFE and \$FFFF. The vector address is the address of the first instruction to be executed after exiting the reset state.

**Figure 6-5. Program Counter (PC)**

### 6.3.5 Condition Code Register

The 8-bit condition code register contains the interrupt mask and five flags that indicate the results of the instruction just executed. Bits 6 and 5 are set permanently to 1. The following paragraphs describe the functions of the condition code register.

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	V	1	1	H	I	N	Z	C
Write:								
Reset:	X	1	1	X	1	X	X	X

X = Indeterminate

**Figure 6-6. Condition Code Register (CCR)**

#### V — Overflow Flag

The CPU sets the overflow flag when a two's complement overflow occurs. The signed branch instructions BGT, BGE, BLE, and BLT use the overflow flag.

- 1 = Overflow
- 0 = No overflow

#### H — Half-Carry Flag

The CPU sets the half-carry flag when a carry occurs between accumulator bits 3 and 4 during an add-without-carry (ADD) or add-with-carry (ADC) operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations. The DAA instruction uses the states of the H and C flags to determine the appropriate correction factor.

- 1 = Carry between bits 3 and 4
- 0 = No carry between bits 3 and 4

#### I — Interrupt Mask

When the interrupt mask is set, all maskable CPU interrupts are disabled. CPU interrupts are enabled when the interrupt mask is cleared. When a CPU interrupt occurs, the interrupt mask is set automatically after the CPU registers are saved on the stack, but before the interrupt vector is fetched.

- 1 = Interrupts disabled
- 0 = Interrupts enabled

#### **NOTE**

*To maintain M6805 Family compatibility, the upper byte of the index register (H) is not stacked automatically. If the interrupt service routine modifies H, then the user must stack and unstack H using the PSHH and PULH instructions.*

After the I bit is cleared, the highest-priority interrupt request is serviced first.

A return-from-interrupt (RTI) instruction pulls the CPU registers from the stack and restores the interrupt mask from the stack. After any reset, the interrupt mask is set and can be cleared only by the clear interrupt mask software instruction (CLI).

#### N — Negative Flag

The CPU sets the negative flag when an arithmetic operation, logic operation, or data manipulation produces a negative result, setting bit 7 of the result.

- 1 = Negative result
- 0 = Non-negative result

**Z — Zero Flag**

The CPU sets the zero flag when an arithmetic operation, logic operation, or data manipulation produces a result of \$00.

1 = Zero result

0 = Non-zero result

**C — Carry/Borrow Flag**

The CPU sets the carry/borrow flag when an addition operation produces a carry out of bit 7 of the accumulator or when a subtraction operation requires a borrow. Some instructions — such as bit test and branch, shift, and rotate — also clear or set the carry/borrow flag.

1 = Carry out of bit 7

0 = No carry out of bit 7

**6.4 Arithmetic/Logic Unit (ALU)**

The ALU performs the arithmetic and logic operations defined by the instruction set.

Refer to the *CPU08 Reference Manual* (document order number CPU08RM/AD) for a description of the instructions and addressing modes and more detail about the architecture of the CPU.

**6.5 Low-Power Modes**

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

**6.5.1 Wait Mode**

The WAIT instruction:

- Clears the interrupt mask (I bit) in the condition code register, enabling interrupts. After exit from wait mode by interrupt, the I bit remains clear. After exit by reset, the I bit is set.
- Disables the CPU clock

**6.5.2 Stop Mode**

The STOP instruction:

- Clears the interrupt mask (I bit) in the condition code register, enabling external interrupts. After exit from stop mode by external interrupt, the I bit remains clear. After exit by reset, the I bit is set.
- Disables the CPU clock

After exiting stop mode, the CPU clock begins running after the oscillator stabilization delay.

**6.6 CPU During Break Interrupts**

If a break module is present on the MCU, the CPU starts a break interrupt by:

- Loading the instruction register with the SWI instruction
- Loading the program counter with \$FFFC:\$FFFD or with \$FEFC:\$FEFD in monitor mode

The break interrupt begins after completion of the CPU instruction in progress. If the break address register match occurs on the last cycle of a CPU instruction, the break interrupt begins immediately.

A return-from-interrupt instruction (RTI) in the break routine ends the break interrupt and returns the MCU to normal operation if the break interrupt has been deasserted.

## 6.7 Instruction Set Summary

Table 6-1 provides a summary of the M68HC08 instruction set.

## Internal Clock Generator Module (ICG)

### 7.1 Introduction

The internal clock generator module (ICG) is used to create a stable clock source for the microcontroller without using any external components. The ICG generates the oscillator output clock (CGMXCLK), which is used by the computer operating properly (COP), low-voltage inhibit (LVI), and other modules. The ICG also generates the clock generator output (CGMOUT), which is fed to the system integration module (SIM) to create the bus clocks. The bus frequency will be one-fourth the frequency of CGMXCLK and one-half the frequency of CGMOUT. Finally, the ICG generates the timebase clock (TBMCLK), which is used in the timebase module (TBM).

### 7.2 Features

Features of the ICG include:

- Selectable external clock generator, either one pin external source or two pin crystal, multiplexed with port pins
- Internal clock generator with programmable frequency output in integer multiples of a nominal frequency (307.2 kHz  $\pm$  25%)
- Frequency adjust (trim) register to improve variability to  $\pm$  2%
- Bus clock software selectable from either internal or external clock (bus frequency range from 76.8 kHz  $\pm$  25% to 9.75 MHz  $\pm$  25% in 76.8 kHz increments — note that for the MC68HC908KX8, MC68HC908KX2, and MC68HC08KX8, do not exceed the maximum bus frequency of 8 MHz at 5.0 V and 4 MHz at 3.0 V)
- Timebase clock automatically selected externally, if external clock is available
- Clock monitor for both internal and external clocks

### 7.3 Functional Description

As shown in [Figure 7-1](#), the ICG contains these major submodules:

- Clock enable circuit
- Internal clock generator

# Internal Clock Generator Module (ICG)

**Figure 7-1. ICG Module Block Diagram**

### 7.3.1 Clock Enable Circuit

The clock enable circuit is used to enable the internal clock (ICLK) or external clock (ECLK) and the port logic which is shared with the oscillator pins (OSC1 and OSC2). The clock enable circuit generates an ICG stop (ICGSTOP) signal which stops all clocks (ICLK, ECLK, and the low-frequency base clock, IBASE). ICGSTOP is set and the ICG is disabled in stop mode if the oscillator enable in stop (OSCENINSTOP) bit in the CONFIG (or MOR) register is clear. The ICG clocks will be enabled in stop mode if OSCENINSTOP is high.

The internal clock enable signal (ICGEN) turns on the ICG which generates ICLK. ICGEN is set (active) whenever the ICGON bit is set and the ICGSTOP signal is clear. When ICGEN is clear, ICLK and IBASE are both low.

The external clock enable signal (ECGEN) turns on the external clock generator which generates ECLK. ECGEN is set (active) whenever the ECGON bit is set and the ICGSTOP signal is clear. ECGON cannot be set unless the external clock enable (EXTCLKEN) bit in the CONFIG (or MOR) register is set. When ECGEN is clear, ECLK is low.

The port B6 enable signal (PB6EN) turns on the port B6 logic. Since port B6 is on the same pin as OSC1, this signal is only active (set) when the external clock function is not desired. Therefore, PB6EN is clear when ECGON is set. PB6EN is not gated with ICGSTOP, which means that if the ECGON bit is set, the port B6 logic will remain disabled in stop mode.

The port B7 enable signal (PB7EN) turns on the port B7 logic. Since port B7 is on the same pin as OSC2, this signal is only active (set) when two-pin oscillator function is not desired. Therefore, PB7EN is clear when ECGON and the external crystal enable (EXTXTALEN) bit in the CONFIG (or MOR) register are both set. PB6EN is not gated with ICGSTOP, which means that if ECGON and EXTXTALEN are set, the port B7 logic will remain disabled in stop mode.

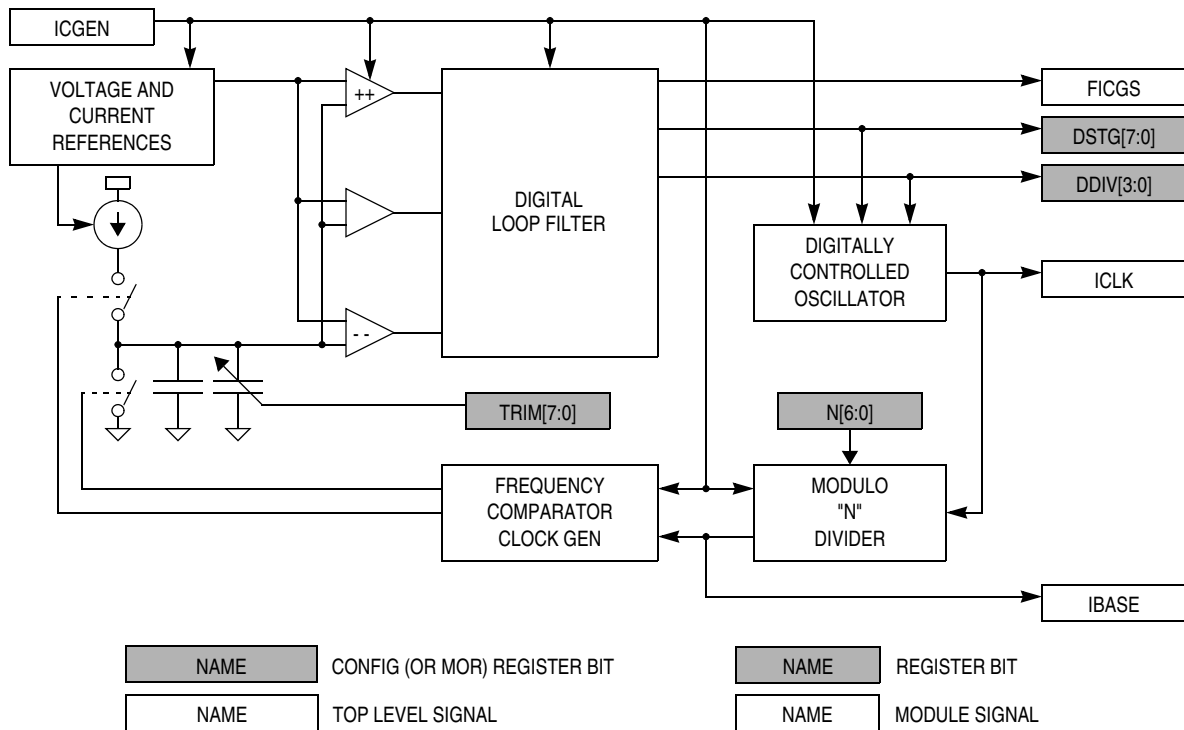

### 7.3.2 Internal Clock Generator

The ICG, shown in [Figure 7-2](#), creates a low frequency base clock (IBASE), which operates at a nominal frequency ( $f_{NOM}$ ) of 307.2 kHz  $\pm$  25%, and an internal clock (ICLK) which is an integer multiple of IBASE. This multiple is the ICG multiplier factor (N), which is programmed in the ICG multiplier register (ICGMR). The ICG is turned off and the output clocks (IBASE and ICLK) are held low when the ICG enable signal (ICGEN) is clear.

The ICG contains:

- A digitally controlled oscillator
- A modulo "N" divider
- A frequency comparator, which contains voltage and current references, a frequency to voltage converter, and comparators
- A digital loop filter

## Internal Clock Generator Module (ICG)

**Figure 7-2. Internal Clock Generator Block Diagram**

### 7.3.2.1 Digitally Controlled Oscillator

The digitally controlled oscillator (DCO) is an inaccurate oscillator which generates the internal clock (ICLK). The clock period of ICLK is dependent on the digital loop filter outputs (DSTG[7:0] and DDIV[3:0]). Because there is only a limited number of bits in DDIV and DSTG, the precision of the output (ICLK) is restricted to a precision of approximately  $\pm 0.202\%$  to  $\pm 0.368\%$  when measured over several cycles (of the desired frequency). Additionally, since the propagation delays of the devices used in the DCO ring oscillator are a measurable fraction of the bus clock period, reaching the long-term precision may require alternately running faster and slower than desired, making the worst case cycle-to-cycle frequency variation  $\pm 6.45\%$  to  $\pm 11.8\%$  (of the desired frequency). The valid values of DDIV:DSTG range from \$000 to \$9FF. For more information on the quantization error in the DCO, see [7.4.4 Quantization Error in DCO Output](#).

### 7.3.2.2 Modulo "N" Divider

The modulo "N" divider creates the low frequency base clock (IBASE) by dividing the internal clock (ICLK) by the ICG multiplier factor (N), contained in the ICG multiplier register (ICGMR). When N is programmed to a \$01 or \$00, the divider is disabled and ICLK is passed through to IBASE undivided. When the ICG is stable, the frequency of IBASE will be equal to the nominal frequency ( $f_{\text{NOM}}$ ) of 307.2 kHz  $\pm 25\%$ .

### 7.3.2.3 Frequency Comparator

The frequency comparator effectively compares the low frequency base clock (IBASE) to a nominal frequency,  $f_{\text{NOM}}$ . First, the frequency comparator converts IBASE to a voltage by charging a known capacitor with a current reference for a period dependent on IBASE. This voltage is compared to a voltage

reference with comparators, whose outputs are fed to the digital loop filter. The dependence of these outputs on the capacitor size, current reference, and voltage reference causes up to  $\pm 25\%$  error in  $f_{\text{NOM}}$ .

### 7.3.2.4 Digital Loop Filter

The digital loop filter (DLF) uses the outputs of the frequency comparator to adjust the internal clock (ICLK) clock period. The DLF generates the DCO divider control bits (DDIV[3:0]) and the DCO stage control bits (DSTG[7:0]), which are fed to the DCO. The DLF first concatenates the DDIV and DSTG registers (DDIV[3:0]:DSTG[7:0]) and then adds or subtracts a value dependent on the relative error in the low frequency base clock's period, as shown in Table 7-1. In some extreme error conditions, such as operating at a  $V_{\text{DD}}$  level which is out of specification, the DLF may attempt to use a value above the maximum (\$9FF) or below the minimum (\$000). In both cases, the value for DDIV will be between \$A and \$F. In this range, the DDIV value will be interpreted the same as \$9 (the slowest condition). Recovering from this condition requires subtracting (increasing frequency) in the normal fashion until the value is again below \$9FF (if the desired value is \$9xx, the value may settle at \$Axx through \$Fxx — this is an acceptable operating condition). If the error is less than  $\pm 15\%$ , the ICG's filter stable indicator (FICGS) is set, indicating relative frequency accuracy to the clock monitor.

All FLASH mask sets other than 0K45D, 1K45D, 0L09H, 1L09H have 15% comparators that improve stability at low temperatures.

**Table 7-1. Correction Sizes from DLF to DCO**

Frequency Error of IBASE compared to $f_{\text{NOM}}$	DDIV[3:0]:DSTG[7:0] Correction	Current to New DDIV[3:0]:DSTG[7:0] <sup>(1)</sup>		Relative Correction in DCO	
		Minimum	Maximum		
$\text{IBASE} < 0.85 f_{\text{NOM}}$	-32 (-\$020)	Minimum	\$xFF to \$xDF	-2/31	-6.45%
		Maximum	\$x20 to \$x00	-2/19	-10.5%
$0.85 f_{\text{NOM}} < \text{IBASE} < f_{\text{NOM}}$	-1 (-\$001)	Minimum	\$xFF to \$xFE	-0.0625/31	-0.202%
		Maximum	\$x01 to \$x00	-0.0625/17.0625	-0.366%
$f_{\text{NOM}} < \text{IBASE} < 1.15 f_{\text{NOM}}$	+1 (+\$001)	Minimum	\$xFE to \$xFF	+0.0625/30.9375	+0.202%
		Maximum	\$x00 to \$x01	+0.0625/17	+0.368%
$1.15 f_{\text{NOM}} < \text{IBASE}$	+32 (+\$020)	Minimum	\$xDF to \$xFF	+2/29	+6.90%
		Maximum	\$x00 to \$x20	+2/17	+11.8%

1. x =Maximum error is independent of value in DDIV[3:0]. DDIV increments or decrements when an addition to DSTG[7:0] carries or borrows.

## 7.3.3 External Clock Generator

The ICG also provides for an external oscillator or external clock source, if desired. The external clock generator, shown in Figure 7-3, contains an external oscillator amplifier and an external clock input path.

### 7.3.3.1 External Oscillator Amplifier

The external oscillator amplifier provides the gain required by an external crystal connected in a Pierce oscillator configuration. The amount of this gain is controlled by the slow external (EXTSLOW) bit in the CONFIG (or MOR) register. When EXTSLOW is set, the amplifier gain is reduced for operating low-frequency crystals (32 kHz to 100 kHz). When EXTSLOW is clear, the amplifier gain will be sufficient for 1 MHz to 8 MHz crystals. EXTSLOW must be configured correctly for the given crystal or the circuit may not operate.

## Internal Clock Generator Module (ICG)

**Figure 7-3. External Clock Generator Block Diagram**

The amplifier is enabled when the external clock generator enable (ECGEN) signal is set and when the external crystal enable (EXTXTALEN) bit in the CONFIG (or MOR) register is set. ECGEN is controlled by the clock enable circuit (see 7.3.1 Clock Enable Circuit), and indicates that the external clock function is desired. When enabled, the amplifier will be connected between the PTB6/(OSC1) and PTB7/(OSC2)/RST pins. Otherwise, the PTB7/(OSC2)/RST pin reverts to its port function. In its typical configuration, the external oscillator requires five external components:

- Crystal,  $X_1$
- Fixed capacitor,  $C_1$
- Tuning capacitor,  $C_2$  (can also be a fixed capacitor)
- Feedback resistor,  $R_B$
- Series resistor,  $R_S$  (included in the diagram to follow strict Pierce oscillator guidelines and may not be required for all ranges of operation, especially with high frequency crystals. Refer to the crystal manufacturer's data for more information.)

### 7.3.3.2 External Clock Input Path

The external clock input path is the means by which the microcontroller uses an external clock source. The input to the path is the PTB6/(OSC1) pin and the output is the external clock (ECLK). The path, which contains input buffering, is enabled when the external clock generator enable signal (ECGEN) is set. When not enabled, the PTB6/(OSC1) pin reverts to its port function.

### 7.3.4 Clock Monitor Circuit

The ICG contains a clock monitor circuit which, when enabled, will continuously monitor both the external clock (ECLK) and the internal clock (ICLK) to determine if either clock source has been corrupted. The clock monitor circuit, shown in Figure 7-4, contains these blocks:

- Clock monitor reference generator
- Internal clock activity detector
- External clock activity detector

Figure 7-4. Clock Monitor Block Diagram

#### 7.3.4.1 Clock Monitor Reference Generator

The clock monitor uses a reference based on one clock source to monitor the other clock source. The clock monitor reference generator generates the external reference clock (EREF) based on the external clock (ECLK) and the internal reference clock (IREF) based on the internal clock (ICLK). To simplify the circuit, the low frequency base clock (IBASE) is used in place of ICLK because it always operates at or

## Internal Clock Generator Module (ICG)

near 307.2 kHz. For proper operation, EREF must be at least twice as slow as IBASE and IREF must be at least twice as slow as ECLK.

To guarantee that IREF is slower than ECLK and EREF is slower than IBASE, one of the signals is divided down. Which signal is divided and by how much is determined by the external slow (EXTSLOW) and external crystal enable (EXTXTALEN) bits in the CONFIG (or MOR) register, according to the rules in [Table 7-2](#).

### NOTE

*Each signal (IBASE and ECLK) is always divided by four. A longer divider is used on either IBASE or ECLK based on the EXTSLOW bit.*

**Table 7-2. Clock Monitor Reference Divider Ratios**

ICGON	ECGON	ECGS	EXTSLOW	EXTXTALEN	External Frequency		EREF Divider Ratio	EREF Frequency	ESTBCLK Divider Ratio	ESTBCLK Frequency	IREF Divider Ratio <sup>(1)</sup>	IREF Frequency
0	x	x	x	x	U		U	U	U	U	Off	0
x	0	0	x	x	0		Off	0	Off	0	U	U
1	1	0	x	0	Minimum	60 Hz	Off	0	16 (ECLK)	3.75 Hz	1*4	76.8 kHz ± 25%
					Maximum	32 MHz				2.0 MHz		
1	1	0	x	1	Minimum	30 kHz	Off	0	4096 (ECLK)	7.324 kHz	1*4	76.8 kHz ± 25%
					Maximum	8 MHz				1.953 kHz		
1	1	1	0	0	Minimum	307.2 kHz	128*4	600 Hz	16 (ECLK)	19.2 kHz	1*4	76.8 kHz ± 25%
					Maximum	32 MHz		62.5 kHz		2.0 MHz		
1	1	1	0	1	Minimum	1 MHz	128*4	1.953 kHz	4096 (ECLK)	244 Hz	1*4	76.8 kHz ± 25%
					Maximum	8 MHz		15.63 kHz		1.953 kHz		
1	1	1	1	0	Minimum	60 Hz	1*4	15 Hz	16 (IBASE) <sup>(2)</sup>	19.2 kHz ± 25%	4096*4	18.75 Hz ± 125%
					Maximum	307.2 kHz		76.8 kHz				
1	1	1	1	1	Minimum	30 kHz	1*4	7.5 kHz	4096 (IBASE) <sup>(2)</sup>	75 Hz ± 25%	16*4	4.8 kHz ± 25%
					Maximum	100 kHz		25.0 kHz				

1. U = Unaffected; refer to section of table where ICGON or ECGON is set to 1.

2. IBASE is always used as the internal frequency (307.2 kHz).

To conserve size, the long divider (divide by 4096) is also used as an external crystal stabilization divider. The divider is reset when the external clock generator is turned off or in STOP (ECGEN is clear). When the external clock generator is first turned on, the external clock generator stable bit (ECGS) will be clear. This condition automatically selects ECLK as the input to the long divider. The external stabilization clock (ESTBCLK) will be ECLK divided by 16 when EXTXTALEN is low or 4096 when EXTXTALEN is high. This time-out allows the crystal to stabilize. The falling edge of ESTBCLK is used to set ECGS (ECGS will set after a full 16 or 4096 cycles). When ECGS is set, the divider returns to its normal function. ESTBCLK may be generated by either IBASE or ECLK, but any clocking will only reinforce the set condition. If ECGS is cleared because the clock monitor determined that ECLK was inactive, the divider will revert to a stabilization divider. Since this will change the EREF and IREF divide ratios, it is important to turn the clock monitor off (CMON = 0) after inactivity is detected to ensure valid recovery.

### 7.3.4.2 Internal Clock Activity Detector

The internal clock activity detector, shown in Figure 7-5, looks for at least one falling edge on the low-frequency base clock (IBASE) every time the external reference (EREF) is low. Since EREF is less than half the frequency of IBASE, this should occur every time. If it does not occur two consecutive times, the internal clock inactivity indicator (IOFF) is set. IOFF will be cleared the next time there is a falling edge of IBASE while EREF is low.

The internal clock stable bit (ICGS) is also generated in the internal clock activity detector. ICGS is set when the internal clock generator's filter stable signal (FICGS) indicates that IBASE is within about 15% of the target  $307.2 \text{ kHz} \pm 25\%$  for two consecutive measurements. ICGS is cleared when FICGS is clear, the internal clock generator is turned off or in STOP (ICGEN is clear), or when IOFF is set.

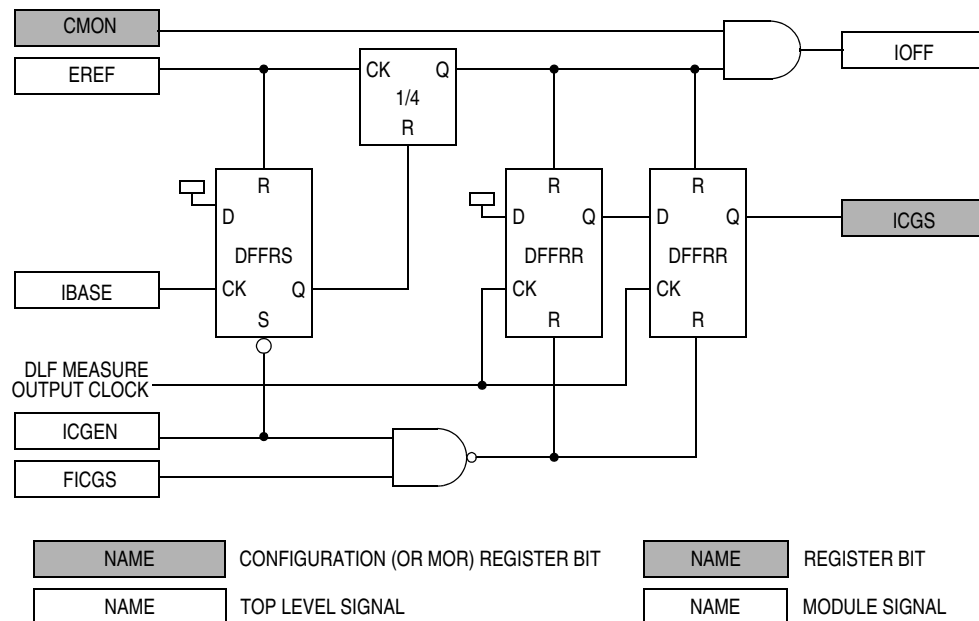

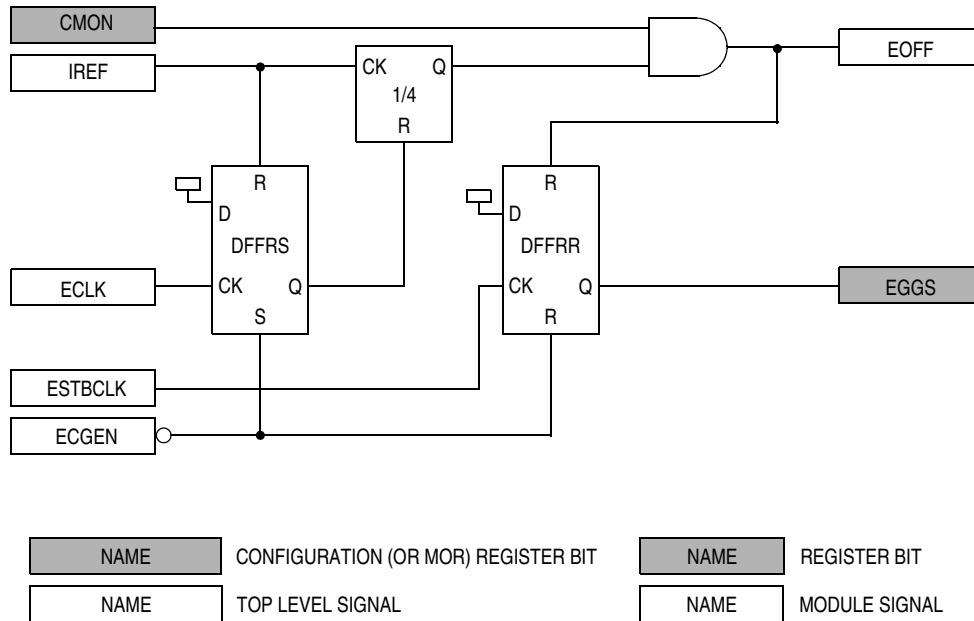

Figure 7-5. Internal Clock Activity Detector

### 7.3.4.3 External Clock Activity Detector

The external clock activity detector, shown in Figure 7-6, looks for at least one falling edge on the external clock (ECLK) every time the internal reference (IREF) is low. Since IREF is less than half the frequency of ECLK, this should occur every time. If it does not occur two consecutive times, the external clock inactivity indicator (EOFF) is set. EOFF will be cleared the next time there is a falling edge of ECLK while IREF is low.

The external clock stable bit (ECGS) is also generated in the external clock activity detector. ECGS is set on a falling edge of the external stabilization clock (ESTBCLK). This will be 4096 ECLK cycles after the external clock generator on bit is set or the MCU exits STOP (ECGEN = 1) if the external crystal enable (EXTXTALEN) in the CONFIG (or MOR) register is set, or 16 cycles when EXTXTALEN is clear. ECGS is cleared when the external clock generator is turned off or in STOP (ECGEN is clear) or when EOFF is set.

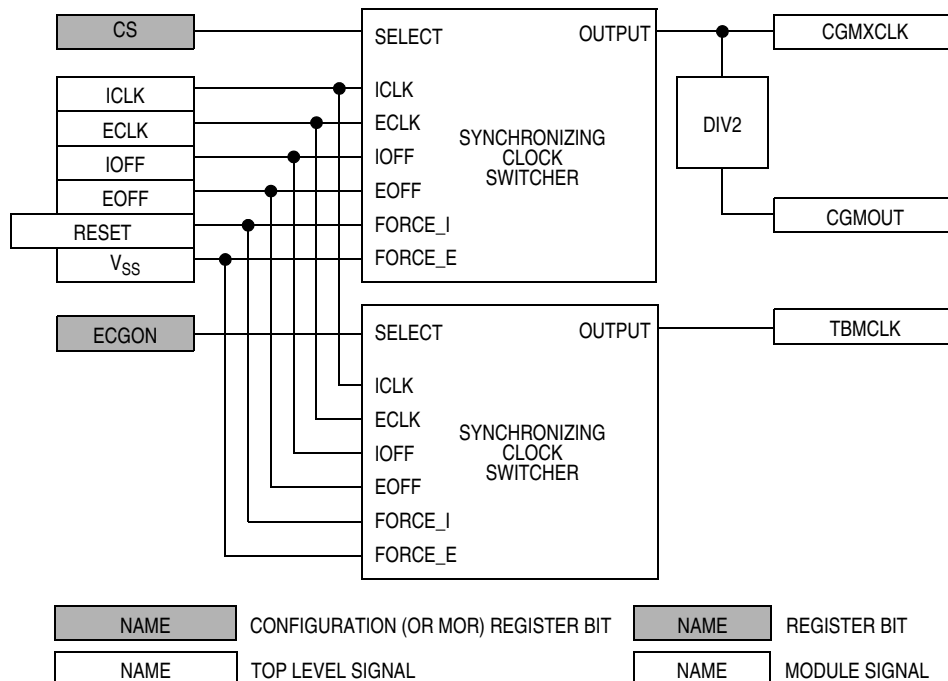

## Internal Clock Generator Module (ICG)

**Figure 7-6. External Clock Activity Detector**

### 7.3.5 Clock Selection Circuit

The clock selection circuit, shown in [Figure 7-7](#), contains two clock switches which generate the oscillator output clock (CGMXCLK) and the timebase clock (TBMCLK) from either the internal clock (ICLK) or the external clock (ECLK). The clock selection circuit also contains a divide-by-two circuit which creates the clock generator output clock (CGMOUT), which generates the bus clocks.

**Figure 7-7. Clock Selection Circuit Block Diagram**

### 7.3.5.1 Clock Selection Switches

The first switch creates the oscillator output clock (CGMXCLK) from either the internal clock (ICLK) or the external clock (ECLK), based on the clock select bit (CS set selects ECLK, clear selects ICLK). When switching the CS bit, both ICLK and ECLK must be on (ICGON and ECGON set). The clock being switched to must also be stable (ICGS or ECGS set).

The second switch creates the timebase clock (TBMCLK) from ICLK or ECLK based on the external clock on bit. When ECGON is set, the switch automatically selects the external clock, regardless of the state of the ECGS bit.

### 7.3.5.2 Clock Switching Circuit

To robustly switch between the internal clock (ICLK) and the external clock (ECLK), the switch assumes the clocks are completely asynchronous, so a synchronizing circuit is required to make the transition. When the select input (the clock select bit for the oscillator output clock switch or the external clock on bit for the timebase clock switch) is changed, the switch will continue to operate off the original clock for between 1 and 2 cycles as the select input is transitioned through one side of the synchronizer. Next, the output will be held low for between 1 and 2 cycles of the new clock as the select input transitions through the other side. Then the output starts switching at the new clock's frequency. This transition guarantees that no glitches will be seen on the output even though the select input may change asynchronously to the clocks. The unpredictability of the transition period is a necessary result of the asynchronicity.

The switch automatically selects ICLK during reset. When the clock monitor is on (CMON is set) and it determines one of the clock sources is inactive (as indicated by the IOFF or EOFF signals), the circuit is forced to select the active clock. There are no clocks for the inactive side of the synchronizer to properly operate, so that side is forced deselected. However, the active side will not be selected until 1 to 2 clock cycles after the IOFF or EOFF signal transitions.

## 7.4 Usage Notes

The ICG has several features which can provide protection to the microcontroller if properly used. There are other features which can greatly simplify usage if certain techniques are employed. This subsection will describe several possible ways to use the ICG and its features. These techniques are not the only ways to use the ICG, and may not be optimum for all environments. In any case, these techniques should only be used as a template, and the user should modify them according to the application's requirements.

These notes include:

- Switching clock sources
- Enabling the clock monitor
- Using clock monitor interrupts
- Quantization error in DCO output
- Switching internal clock frequencies
- Nominal frequency settling time
- Improving frequency settling time
- Trimming frequency

**Figure 7-9. Code Example for Enabling the Clock Monitor**

### 7.4.3 Using Clock Monitor Interrupts

The clock monitor circuit can be used to recover from perilous situations such as crystal loss. To use the clock monitor effectively, the following notes should be observed:

- Enable the clock monitor and clock monitor interrupts.
- The first statement in the clock monitor interrupt service routine (CMISR) should be a read to the ICG control register (ICGCR) to verify the clock monitor flag (CMF) is set. This is also the first step in clearing the CMF bit.
- The second statement in the CMISR should be a write to the ICGCR to clear the CMF bit (write the bit low). Writing the bit high will not affect it. This statement does not need to immediately follow the first, but must be contained in the CMISR.
- The third statement in the CMISR should be to clear the CMON bit. This is required to ensure proper reconfiguration of the reference dividers. This statement must also be contained in the CMISR.
- Although the clock monitor can only be enabled when both clocks are stable (ICGS is set or ECGS is set), it will remain set if one of the clocks goes unstable.
- The clock monitor only works if the external slow (EXTSLOW) bit in the CONFIG (or MOR) register is set to the correct value.
- The internal and external clocks must both be enabled and running in order to use the clock monitor.
- When the clock monitor detects inactivity, the inactive clock is automatically deselected and the active clock selected as the source for CGMXCLK and TBMCLK. The CMISR can use the state of the CS bit to check which clock is inactive.
- When the clock monitor detects inactivity, the application may have been subjected to extreme conditions which may have affected other circuits. The CMISR should take any appropriate precautions.

## 7.4.4 Quantization Error in DCO Output

The digitally controlled oscillator (DCO) is comprised of three major sub-blocks:

- Binary weighted divider
- Variable-delay ring oscillator
- Ring oscillator fine-adjust circuit

Each of these blocks affects the clock period of the internal clock (ICLK). Since these blocks are controlled by the digital loop filter (DLF) outputs DDIV and DSTG, the output of the DCO can only change in quantized steps as the DLF increments or decrements its output. The following subsections describe how each block will affect the output frequency.

### 7.4.4.1 Digitally Controlled Oscillator

The digitally controlled oscillator (DCO) is an inaccurate oscillator which generates the internal clock (ICLK), whose clock period is dependent on the digital loop filter outputs (DSTG[7:0] and DDIV[3:0]). Because of the digital nature of the DCO, the clock period of ICLK will change in quantized steps. This will create a clock period difference, or quantization error (Q-ERR) from one cycle to the next. Over several cycles or for longer periods, this error is divided out until it reaches a minimum error of 0.202% to 0.368%. The dependence of this error on the DDIV[3:0] value and the number of cycles the error is measured over is shown in [Table 7-3](#).

**Table 7-3. Quantization Error in ICLK**

DDIV[3:0]	ICLK Cycles	Bus Cycles	$\tau_{\text{ICLK}}$ Q-ERR
%0000 (min)	1	NA	6.45% – 11.8%
%0000 (min)	4	1	1.61% – 2.94%
%0000 (min)	≥ 32	≥ 8	0.202% – 0.368%
%0001	1	NA	3.23% – 5.88%
%0001	4	1	0.806% – 1.47%
%0001	≥ 16	≥ 4	0.202% – 0.368%
%0010	1	NA	1.61% – 2.94%
%0010	4	1	0.403% – 0.735%
%0010	≥ 8	≥ 2	0.202% – 0.368%
%0011	1	NA	0.806% – 1.47%
%0011	≥ 4	≥ 1	0.202% – 0.368%
%0100	1	NA	0.403% – 0.735%
%0100	≥ 2	≥ 1	0.202% – 0.368%
%0101 – %1001 (max)	≥ 1	≥ 1	0.202% – 0.368%

### 7.4.4.2 Binary Weighted Divider

The binary weighted divider divides the output of the ring oscillator by a power of 2, specified by the DCO divider control bits (DDIV[3:0]). DDIV maximizes at %1001 (values of %1010 through %1111 are interpreted as %1001), which corresponds to a divide by 512. When DDIV is %0000, the ring oscillator's output is divided by 1. Incrementing DDIV by one will double the period; decrementing DDIV will halve the period. The DLF cannot directly increment or decrement DDIV; DDIV is only incremented or decremented when an addition or subtraction to DSTG carries or borrows.

### 7.4.4.3 Variable-Delay Ring Oscillator

The variable-delay ring oscillator's period is adjustable from 17 to 31 stage delays, in increments of two, based on the upper three DCO stage control bits (DSTG[7:5]). A DSTG[7:5] of %000 corresponds to 17 stage delays; DSTG[7:5] of %111 corresponds to 31 stage delays. Adjusting the DSTG[5] bit has a 6.45% to 11.8% effect on the output frequency. This also corresponds to the size correction made when the frequency error is greater than  $\pm 15\%$ . The value of the binary weighted divider does not affect the relative change in output clock period for a given change in DSTG[7:5].

### 7.4.4.4 Ring Oscillator Fine-Adjust Circuit

The ring oscillator fine-adjust circuit causes the ring oscillator to effectively operate at non-integer numbers of stage delays by operating at two different points for a variable number of cycles specified by the lower five DCO stage control bits (DSTG[4:0]). For example, when DSTG[7:5] is %011, the ring oscillator nominally operates at 23 stage delays. When DSTG[4:0] is %00000, the ring will always operate at 23 stage delays. When DSTG[4:0] is %00001, the ring will operate at 25 stage delays for one of 32 cycles and at 23 stage delays for 31 of 32 cycles. Likewise, when DSTG[4:0] is %11111, the ring operates at 25 stage delays for 31 of 32 cycles and at 23 stage delays for one of 32 cycles. When DSTG[7:5] is %111, similar results are achieved by including a variable divide-by-two, so the ring operates at 31 stages for some cycles and at 17 stage delays, with a divide-by-two for an effective 34 stage delays, for the remainder of the cycles. Adjusting the DSTG[0] bit has a 0.202% to 0.368% effect on the output clock period. This corresponds to the minimum size correction made by the DLF, and the inherent, long term quantization error in the output frequency.

## 7.4.5 Switching Internal Clock Frequencies

The frequency of the internal clock (ICLK) may need to be changed for some applications. For example, if the reset condition does not provide the correct frequency, or if the clock is slowed down for a low power mode (or sped up after a low-power mode), the frequency must be changed by programming the internal clock multiplier factor (N). The frequency of ICLK is N times the frequency of IBASE, which is 307.2 kHz  $\pm 25\%$ .

Before switching frequencies by changing the N value, the clock monitor must be disabled. This is because when N is changed, the frequency of the low-frequency base clock (IBASE) will change proportionally until the digital loop filter has corrected the error. Since the clock monitor uses IBASE, it could erroneously detect an inactive clock. The clock monitor cannot be re-enabled until the Internal Clock is stable again (ICGS is set).

The following flow is an example of how to change the clock frequency:

- Verify there is no clock monitor Interrupt by reading the CMF bit
- Turn off the clock monitor
- If desired, switch to the external clock (see [7.4.1 Switching Clock Sources](#))
- Change the value of N
- Switch back to internal (see [7.4.1 Switching Clock Sources](#)), if desired
- Turn on the clock monitor (see [7.4.2 Enabling the Clock Monitor](#)), if desired

## 7.4.6 Nominal Frequency Settling Time

Because the clock period of the internal clock (ICLK) is dependent on the digital loop filter outputs (DDIV and DSTG) which cannot change instantaneously, ICLK will temporarily operate at an incorrect clock

## Internal Clock Generator Module (ICG)

period when any of the operating condition changes. This happens whenever the part is reset, the ICG multiply factor (N) is changed, the ICG trim factor (TRIM) is changed, or the internal clock is enabled after inactivity (STOP or disabled operation). The time that the ICLK takes to adjust to the correct period is known as the settling time.

Settling time depends primarily on how many corrections it takes to change the clock period, and the period of each correction. Since the corrections require four periods of the low-frequency base clock ( $4 \cdot \tau_{IBASE}$ ), and since ICLK is N (the ICG multiply factor for the desired frequency) times faster than IBASE, each correction takes  $4 \cdot N \cdot \tau_{ICLK}$ . The period of ICLK, however, will vary as the corrections occur.

### 7.4.6.1 Settling To Within 15%

All FLASH mask sets other than 0K45D, 1K45D, 0L09H, 1L09H have 15% comparators that improve stability at low temperatures.

When the error is greater than 15%, the filter takes eight corrections to double or halve the clock period. Due to how the DCO increases or decreases the clock period, the total period of these eight corrections is approximately 11 times the period of the fastest correction. (If the corrections were perfectly linear, the total period would be 11.5 times the minimum period; however, the ring must be slightly nonlinear.) Therefore, the total time it takes to double or halve the clock period is  $44 \cdot N \cdot \tau_{ICLKFAST}$ .

If the clock period needs more than doubled or halved, the same relationship applies, only for each time the clock period needs doubled, the total number of cycles doubles. That is, when transitioning from fast to slow, going from the initial speed to half speed takes  $44 \cdot N \cdot \tau_{ICLKFAST}$ ; from half speed to quarter speed takes  $88 \cdot N \cdot \tau_{ICLKFAST}$ ; going from quarter speed to eighth speed takes  $176 \cdot N \cdot \tau_{ICLKFAST}$ ; and so on. This series can be expressed as  $(2^x - 1) \cdot 44 \cdot N \cdot \tau_{ICLKFAST}$ , where x is the number of times the speed needs doubled or halved. Since  $2^x$  happens to be equal to  $\tau_{ICLKSLOW} / \tau_{ICLKFAST}$ , the equation reduces to  $44 \cdot N \cdot (\tau_{ICLKSLOW} - \tau_{ICLKFAST})$ .

#### NOTE

*Increasing speed takes much longer than decreasing speed since N is higher. This can be expressed in terms of the initial clock period ( $\tau_1$ ) minus the final clock period ( $\tau_2$ ) as such:*

$$\tau_{15} = \text{abs}[44N(\tau_1 - \tau_2)]$$

Once the clock period is within 15% of the desired clock period, the internal clock stable bit (ICGS) will be set and the clock frequency is usable, although the error will be as high as 15%.

### 7.4.6.2 Total Settling Time

Once the clock period is within 15% of the desired clock period, the filter starts making minimum adjustments. In this mode, each correction will adjust the frequency between 0.202% and 0.368%. A maximum of 88 corrections will be required to get to the minimum error. Each correction takes approximately the same period of time, or  $4 \cdot \tau_{IBASE}$ . This makes 88 corrections ( $352 \cdot \tau_{IBASE}$ ) to get from 15% to the minimum error. The total time to the minimum error is:

$$\tau_{tot} = \text{abs}[44N(\tau_1 - \tau_2)] + 352\tau_{IBASE}$$

The equations for  $\tau_{15}$ ,  $\tau_5$ , and  $\tau_{tot}$  are dependent on the actual initial and final clock periods  $\tau_1$  and  $\tau_2$ , not the nominal. This means the variability in the ICLK frequency due to process, temperature and voltage must be considered. Additionally, other process factors and noise can affect the actual tolerances of the points at which the filter changes modes. This means a worst case adjustment of up to 35% (ICLK clock

period tolerance plus 10%) must be added. This adjustment can be reduced with trimming. Table 7-4 shows some typical values for settling time.

**Table 7-4. Typical Settling Time Examples**

$\tau_1$	$\tau_2$	N	$\tau_{15}$	$\tau_{tot}$
1/ (6.45 MHz)	1/ (25.8 MHz)	84	430 $\mu$ s	1165 $\mu$ s
1/ (25.8 MHz)	1/ (6.45 MHz)	21	107 $\mu$ s	840 $\mu$ s
1/ (25.8 MHz)	1/ (307.2 kHz)	1	141 $\mu$ s	875 $\mu$ s
1/ (307.2 kHz)	1/ (25.8 MHz)	84	11.9 ms	12.6 ms

### 7.4.7 Trimming Frequency on the Internal Clock Generator

The unadjusted frequency of the low-frequency base clock (IBASE), when the comparators in the frequency comparator indicate zero error, will vary as much as  $\pm 25\%$  due to process, temperature, and voltage dependencies. These dependencies are in the voltage and current references, the offset of the comparators, and the internal capacitor. The voltage and temperature dependencies have been designed to be a maximum of approximately  $\pm 1\%$  error. The process dependencies account for the rest.

Fortunately, for an individual part, the process dependencies are constant. An individual part can operate at approximately  $\pm 2\%$  variance from its unadjusted operating point over the entire spec range of the application. If the unadjusted operating point can be changed, the entire variance can be limited to  $\pm 2\%$ .

The method of changing the unadjusted operating point is by changing the size of the capacitor. This capacitor is designed with 639 equally sized units. 384 of these units are always connected. The remaining 255 units are put in by adjusting the ICG trim factor (TRIM). The default value for TRIM is \$80, or 128 units, making the default capacitor size 512. Each unit added or removed will adjust the output frequency by about  $\pm 0.195\%$  of the unadjusted frequency (adding to TRIM will decrease frequency). Therefore, the frequency of IBASE can be changed to  $\pm 25\%$  of its unadjusted value, which is enough to cancel the process variability mentioned before.

The best way to trim the internal clock is to use the timer to measure the width of an input pulse on an input capture pin (this pulse must be supplied by the application and should be as long or wide as possible). Considering the prescale value of the timer and the theoretical (zero error) frequency of the bus (307.2 kHz \* N/4), the error can be calculated. This error, expressed as a percentage, can be divided by 0.195% and the resultant factor added or subtracted from TRIM. This process should be repeated to eliminate any residual error.

## 7.5 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

### 7.5.1 Wait Mode

The ICG remains active in wait mode. If enabled, the ICG interrupt to the CPU can bring the MCU out of wait mode.

In some applications, low power consumption is desired in wait mode and a high frequency clock is not needed. In these applications, reduce power consumption by either selecting a low-frequency external clock and turn the internal clock generator off, or reduce the bus frequency by minimizing the ICG multiplier factor (N) before executing the WAIT instruction.

## 7.5.2 Stop Mode

The value of the oscillator enable in stop (OSCENINSTOP) bit in the CONFIG (or MOR) register determines the behavior of the ICG in stop mode. If OSCENINSTOP is low, the ICG is disabled in stop and, upon execution of the STOP instruction, all ICG activity will cease and the output clocks (CGMXCLK, CGMOUT, and TBMCLK) will be held low. Power consumption will be minimal.

If OSCENINSTOP is high, the ICG is enabled in stop and activity will continue. This is useful if the timebase module (TBM) is required to bring the MCU out of stop mode. ICG interrupts will not bring the MCU out of stop mode in this case.

During STOP, if OSCENINSTOP is low, several functions in the ICG are affected. The stable bits (ECGS and ICGS) are cleared, which will enable the external clock stabilization divider upon recovery. The clock monitor is disabled (CMON = 0) which will also clear the clock monitor interrupt enable (CMIE) and clock monitor flag (CMF) bits. The CS, ICGON, ECGON, N, TRIM, DDIV, and DSTG bits are unaffected.

## 7.6 CONFIG (or MOR) Register Options

There are four CONFIG (or MOR) register options that affect the functionality of the ICG. These options are:

- EXTCLKEN (external clock enable)
- EXTXTALEN (external crystal enable)
- EXTSLOW (slow external clock)
- OSCENINSTOP (oscillator enable in stop)

All CONFIG (or MOR) register options will have a default setting.

### 7.6.1 External Clock Enable (EXTCLKEN)

External clock enable (EXTCLKEN), when set, enables the ECGON bit to be set. ECGON turns on the external clock input path through the PTB6/(OSC1) pin. When EXTCLKEN is clear, ECGON cannot be set and PTB6/(OSC1) will always perform the PTB6 function.

The default state for this option is clear.

### 7.6.2 External Crystal Enable (EXTXTALEN)

External crystal enable (EXTXTALEN), when set, will enable an amplifier to drive the PTB7/(OSC2)/ $\overline{\text{RST}}$  pin from the PTB6/(OSC1) pin. The amplifier will only drive if the external clock enable (EXTCLKEN) bit and the ECGON bit are also set. If EXTCLKEN or ECGON are clear, PTB7/(OSC2)/ $\overline{\text{RST}}$  will perform the PTB7 function. When EXTXTALEN is clear, PTB7/(OSC2)/ $\overline{\text{RST}}$  will always perform the PTB7 function.

EXTXTALEN, when set, also configures the clock monitor to expect an external clock source in the valid range of crystals (30 kHz to 100 kHz or 1 MHz to 8 MHz). When EXTXTALEN is clear, the clock monitor will expect an external clock source in the valid range for externally generated clocks when using the clock monitor (60 Hz to 32 MHz).

EXTXTALEN, when set, also configures the external clock stabilization divider in the clock monitor for a 4096 cycle time-out to allow the proper stabilization time for a crystal. When EXTXTALEN is clear, the stabilization divider is configured to 16 cycles since an external clock source does not need a start-up time.

The default state for this option is clear.

### 7.6.3 Slow External Clock (EXTSLOW)

Slow external clock (EXTSLOW), when set, will decrease the drive strength of the oscillator amplifier, enabling low-frequency crystal operation (30 kHz–100 kHz) if properly enabled with the external clock enable (EXTCLKEN) and external crystal enable (EXTXTALEN) bits. When clear, EXTSLOW enables high-frequency crystal operation (1 MHz to 8 MHz).

EXTSLOW, when set, also configures the clock monitor to expect an external clock source that is slower than the low-frequency base clock (60 Hz–307.2 kHz). When EXTSLOW is clear, the clock monitor will expect an external clock faster than the low-frequency base clock (307.2 kHz–32 MHz).

The default state for this option is clear.

### 7.6.4 Oscillator Enable In Stop (OSCENINSTOP)

Oscillator enable in stop (OSCENINSTOP), when set, will enable the ICG to continue to generate clocks (either CGMXCLK, CGMOUT, or TBMCLK) in stop mode. This function is used to keep the timebase running while the rest of the microcontroller stops. When OSCENINSTOP is clear, all clock generation will cease and CGMXCLK, CGMOUT, and TBMCLK will be forced low during stop.

The default state for this option is clear.

## 7.7 I/O Registers

The ICG contains five registers, summarized in [Figure 7-10](#). These registers are:

- ICG control register
- ICG multiplier register
- ICG trim register
- ICG DCO divider control register
- ICG DCO stage control register

Several of the bits in these registers have interaction where the state of one bit may force another bit to a particular state or prevent another bit from being set or cleared. A summary of this interaction is shown in [Table 7-5](#).

us, uc, uwRegister bit cannot be set, cleared, or written (respectively) in the given condition.

## 7.7.1 ICG Control Register

The ICG control register (ICGCR) contains the control and status bits for the internal clock generator, external clock generator, and clock monitor as well as the Clock Select and Interrupt Enable bits.

**Figure 7-11. ICG Control Register (ICGCR)**

### CMIE — Clock Monitor Interrupt Enable Bit

This read/write bit enables clock monitor interrupts. An interrupt will occur when both CMIE and CMF are set. CMIE can be set when the CMON bit has been set for at least one cycle. CMIE is forced clear when CMON is clear or during reset.

- 1 = Clock monitor interrupts enabled
- 0 = Clock monitor interrupts disabled

### CMF — Clock Monitor Interrupt Flag

This read-only bit is set when the clock monitor determines that either ICLK or ECLK becomes inactive and the CMON bit is set. This bit is cleared by first reading the bit while it is set, followed by writing the bit low. This bit is forced clear when CMON is clear or during reset.

- 1 = Either ICLK or ECLK have become inactive
- 0 = ICLK and ECLK have not become inactive since the last read of the ICGCR, or the clock monitor is disabled

### CMON — Clock Monitor On Bit

This read/write bit enables the clock monitor. CMON can be set when both ICLK and ECLK have been on and stable for at least one bus cycle (ICGON, ECGON, ICGS, and ECGS are all set). CMON is forced set when CMF is set, to avoid inadvertent clearing of CMF. CMON is forced clear when either ICGON or ECGON are clear, during STOP with OSCENINSTOP low, or during reset.

- 1 = Clock monitor output enabled
- 0 = Clock monitor output disabled

### CS — Clock Select Bit

This read/write bit determines which clock will generate the oscillator output clock (CGMXCLK). This bit can be set when ECGON and ECGS have been set for at least one bus cycle and can be cleared when ICGON and ICGS have been set for at least one bus cycle. This bit is forced set when the clock monitor determines the internal clock (ICLK) is inactive or when ICGON is clear. This bit is forced clear when the clock monitor determines that the external clock (ECLK) is inactive, when ECGON is clear, or during reset.

- 1 = External clock (ECLK) sources CGMXCLK
- 0 = Internal clock (ICLK) sources CGMXCLK

**ICGON — Internal Clock Generator On Bit**

This read/write bit enables the internal clock generator. ICGON can be cleared when the CS bit has been set and the CMON bit has been clear for at least one bus cycle. ICGON is forced set when the CMON bit is set, the CS bit is clear, or during reset.

- 1 = Internal clock generator enabled
- 0 = Internal clock generator disabled

**ICGS — Internal Clock Generator Stable Bit**

This read-only bit indicates when the internal clock generator has determined that the internal clock (ICLK) is within about 15% of the desired value. This bit is forced clear when the clock monitor determines the ICLK is inactive, when ICGON is clear, when the ICG multiplier register (ICGMR) is written, when the ICG trim register (ICGTR) is written, during STOP with OSCENINSTOP low, or during reset.

- 1 = Internal clock is within 15% of the desired value
- 0 = Internal clock may not be within 15% of the desired value

**ECGON — External Clock Generator On Bit**

This read/write bit enables the external clock generator. ECGON can be cleared when the CS and CMON bits have been clear for at least one bus cycle. ECGON is forced set when the CMON bit or the CS bit is set. ECGON is forced clear during reset.

- 1 = External clock generator enabled
- 0 = External clock generator disabled

**ECGS — External Clock Generator Stable Bit**

This read-only bit indicates when at least 4096 external clock (ECLK) cycles have elapsed since the external clock generator was enabled. This is not an assurance of the stability of ECLK but is meant to provide a start-up delay. This bit is forced clear when the clock monitor determines ECLK is inactive, when ECGON is clear, during STOP with OSCENINSTOP low, or during reset.

- 1 = 4096 ECLK cycles have elapsed since ECGON was set
- 0 = External clock is unstable, inactive, or disabled

**7.7.2 ICG Multiplier Register**

**Figure 7-12. ICG Multiplier Register (ICGMR)**

**N6:N0 — ICG Multiplier Factor Bits**

These read/write bits change the multiplier used by the internal clock generator. The internal clock (ICLK) will be  $(307.2 \text{ kHz} \pm 25\%) * N$ . A value of \$00 in this register is interpreted the same as a value of \$01. This register cannot be written when the CMON bit is set. Reset sets this factor to \$15 (decimal 21) for default frequency of  $6.45 \text{ MHz} \pm 25\%$  ( $1.613 \text{ MHz} \pm 25\%$  bus).

### 7.7.3 ICG Trim Register

Figure 7-13. ICG Trim Register (ICGTR)

#### TRIM7:TRIM0 — ICG Trim Factor Bits

These read/write bits change the size of the internal capacitor used by the internal clock generator. By testing the frequency of the internal clock and incrementing or decrementing this factor accordingly, the accuracy of the internal clock can be improved to  $\pm 2\%$ . Incrementing this register by one decreases the frequency by 0.195% of the unadjusted value. Decrementing this register by one increases the frequency by 0.195%. This register cannot be written when the CMON bit is set. Reset sets these bits to \$80, centering the range of possible adjustment.

### 7.7.4 ICG DCO Divider Register

Figure 7-14. ICG DCO Divider Control Register (ICGDVR)

#### DDIV3:DDIV0 — ICG DCO Divider Control Bits

These bits indicate the number of divide-by-twos (DDIV) that follow the digitally controlled oscillator. When ICGON is set, DDIV is controlled by the digital loop filter. The range of valid values for DDIV is from \$0 to \$9. Values of \$A–\$F are interpreted the same as \$9. Since the DCO is active during reset, reset has no effect on DSTG and the value may vary.

### 7.7.5 ICG DCO Stage Register

Figure 7-15. ICG DCO Stage Control Register (ICGDSR)

**DSTG7:DSTG0 — ICG DCO Stage Control Bits**

These bits indicate the number of stages (above the minimum) in the digitally controlled oscillator. The total number of stages is approximately equal to \$1FF, so changing DSTG from \$00 to \$FF will approximately double the period. Incrementing DSTG will increase the period (decrease the frequency) by 0.202% to 0.368% (decrementing has the opposite effect). DSTG cannot be written when ICGON is set to prevent inadvertent frequency shifting. When ICGON is set, DSTG is controlled by the digital loop filter. Since the DCO is active during reset, reset has no effect on DSTG and the value may vary.

# Chapter 8

## External Interrupt (IRQ)

### 8.1 Introduction

The external interrupt (IRQ) module provides a maskable interrupt input.

### 8.2 Features

Features of the IRQ module include:

- A dedicated external interrupt pin ( $\overline{\text{IRQ1}}$ )
- IRQ1 interrupt control bits
- Internal pullup resistor
- Hysteresis buffer
- Programmable edge-only or edge- and level-interrupt sensitivity
- Automatic interrupt acknowledge

### 8.3 Functional Description

A logic 0 applied to the external interrupt pin can latch a central processor unit (CPU) interrupt request. [Figure 8-2](#) shows the structure of the IRQ module.

Interrupt signals on the  $\overline{\text{IRQ1}}$  pin are latched into the IRQ1 latch. An interrupt latch remains set until one of these actions occurs:

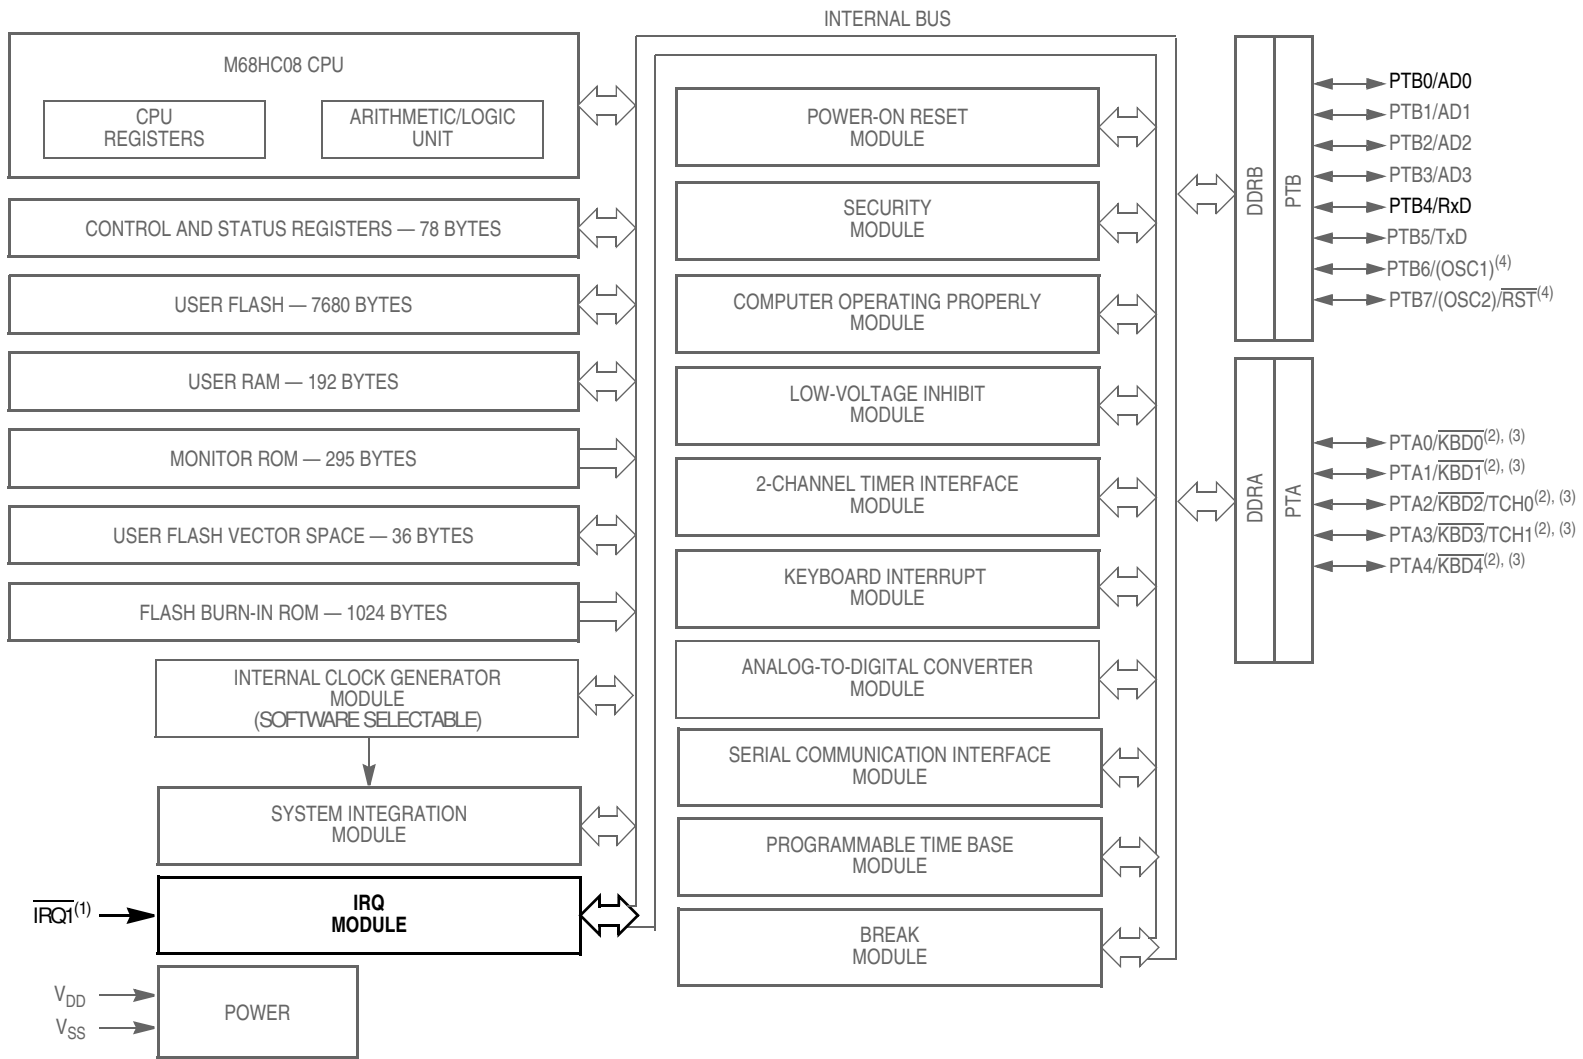

- Vector fetch — A vector fetch automatically generates an interrupt acknowledge signal that clears the latch that caused the vector fetch.
- Software clear — Software can clear an interrupt latch by writing to the appropriate acknowledge bit in the interrupt status and control register (ISCR). Writing a 1 to the ACK1 bit clears the IRQ1 latch.
- Reset — A reset automatically clears the interrupt latch.

The external interrupt pin is falling-edge triggered and is software- configurable to be both falling-edge and low-level triggered. The MODE1 bit in the ISCR controls the triggering sensitivity of the  $\overline{\text{IRQ1}}$  pin.

When an interrupt pin is edge-triggered only, the interrupt latch remains set until a vector fetch, software clear, or reset occurs.

When an interrupt pin is both falling-edge and low-level triggered, the interrupt latch remains set until both of these occur:

- Vector fetch or software clear
- Return of the interrupt pin to logic 1

Notes:

1. Pin contains integrated pullup resistor
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.

**Figure 8-1. Block Diagram Highlighting IRQ Block and Pins**

**Figure 8-2. IRQ Block Diagram**

The vector fetch or software clear may occur before or after the interrupt pin returns to logic 1. As long as the pin is low, the interrupt request remains pending. A reset will clear the latch and the MODE1 control bit, thereby clearing the interrupt even if the pin stays low.

When set, the IMASK1 bit in the ISCR masks all external interrupt requests. A latched interrupt request is not presented to the interrupt priority logic unless the IMASK1 bit is clear.

**NOTE**

*The interrupt mask (I) in the condition code register (CCR) masks all interrupt requests, including external interrupt requests.*

### 8.4 $\overline{\text{IRQ1}}$ Pin

A logic 0 on the  $\overline{\text{IRQ1}}$  pin can latch an interrupt request into the IRQ1 latch. A vector fetch, software clear, or reset clears the IRQ1 latch.

If the MODE1 bit is set, the  $\overline{\text{IRQ1}}$  pin is both falling-edge sensitive and low-level sensitive. With MODE1 set, both of the following actions must occur to clear the IRQ1 latch:

- Vector fetch or software clear — A vector fetch generates an interrupt acknowledge signal to clear the latch. Software may generate the interrupt acknowledge signal by writing a 1 to the ACK1 bit in the interrupt status and control register (ISCR). The ACK1 bit is useful in applications that poll the  $\overline{\text{IRQ1}}$  pin and require software to clear the IRQ1 latch. Writing to the ACK1 bit can also prevent spurious interrupts due to noise. Setting ACK1 does not affect subsequent transitions on the  $\overline{\text{IRQ1}}$  pin. A falling edge on the  $\overline{\text{IRQ1}}$  pin that occurs after writing to the ACK1 bit latches another interrupt request. If the IRQ1 mask bit, IMASK1, is clear, the CPU loads the program counter with the vector address at locations \$FFFA and \$FFFB.
- Return of the  $\overline{\text{IRQ1}}$  pin to logic 1 — As long as the  $\overline{\text{IRQ1}}$  pin is at logic 0, the IRQ1 latch remains set.

## External Interrupt (IRQ)

The vector fetch or software clear and the return of the  $\overline{\text{IRQ1}}$  pin to logic 1 can occur in any order. The interrupt request remains pending as long as the  $\overline{\text{IRQ1}}$  pin is at logic 0. A reset will clear the latch and the MODE1 control bit, thereby clearing the interrupt even if the pin stays low.

If the MODE1 bit is clear, the  $\overline{\text{IRQ1}}$  pin is falling-edge sensitive only. With MODE1 clear, a vector fetch or software clear immediately clears the IRQ1 latch.

The IRQF1 bit in the ISCR can be used to check for pending interrupts. The IRQF1 bit is not affected by the IMASK1 bit, which makes it useful in applications where polling is preferred.

Use the branch if interrupt pin is high (BIH) or branch if interrupt pin is low (BIL) instruction to read the logic level on the  $\overline{\text{IRQ1}}$  pin.

### NOTE

*When using the level-sensitive interrupt trigger, avoid false interrupts by masking interrupt requests in the interrupt routine.*

## 8.5 IRQ Status and Control Register

The IRQ status and control register (ISCR) controls and monitors operation of the IRQ module. The ISCR has these functions:

- Shows the state of the IRQ1 interrupt flag
- Clears the IRQ1 interrupt latch
- Masks IRQ1 interrupt request
- Controls triggering sensitivity of the  $\overline{\text{IRQ1}}$  interrupt pin

Address: \$001D

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	IRQF1	0	IMASK1	MODE1
Write:	R	R	R	R	R	ACK1		
Reset:	0	0	0	0	U	0	0	0

R = Reserved      U = Unaffected

**Figure 8-3. IRQ Status and Control Register (ISCR)**

### IRQF1 — IRQ1 Flag Bit

This read-only status bit is high when the IRQ1 interrupt is pending.

- 1 = IRQ1 interrupt pending
- 0 = IRQ1 interrupt not pending

### ACK1 — IRQ1 Interrupt Request Acknowledge Bit

Writing a 1 to this write-only bit clears the IRQ1 latch. ACK1 always reads as 0. Reset clears ACK1.

### IMASK1 — IRQ1 Interrupt Mask Bit

Writing a 1 to this read/write bit disables IRQ1 interrupt requests. Reset clears IMASK1.

- 1 = IRQ1 interrupt requests disabled
- 0 = IRQ1 interrupt requests enabled

### MODE1 — IRQ1 Edge/Level Select Bit

This read/write bit controls the triggering sensitivity of the  $\overline{\text{IRQ1}}$  pin. Reset clears MODE1.

- 1 = IRQ1 interrupt requests on falling edges and low levels
- 0 = IRQ1 interrupt requests on falling edges only

# Chapter 9

## Keyboard Interrupt Module (KBI)

### 9.1 Introduction

The keyboard interrupt module (KBI) provides five independently maskable external interrupt pins.

### 9.2 Features

KBI features include:

- Five keyboard interrupt pins, on the MC68HC08KX8, are with separate keyboard interrupt enable bits and one keyboard interrupt mask
- Hysteresis buffers
- Programmable edge-only or edge- and level-interrupt sensitivity
- Automatic interrupt acknowledge
- Exit from low-power modes

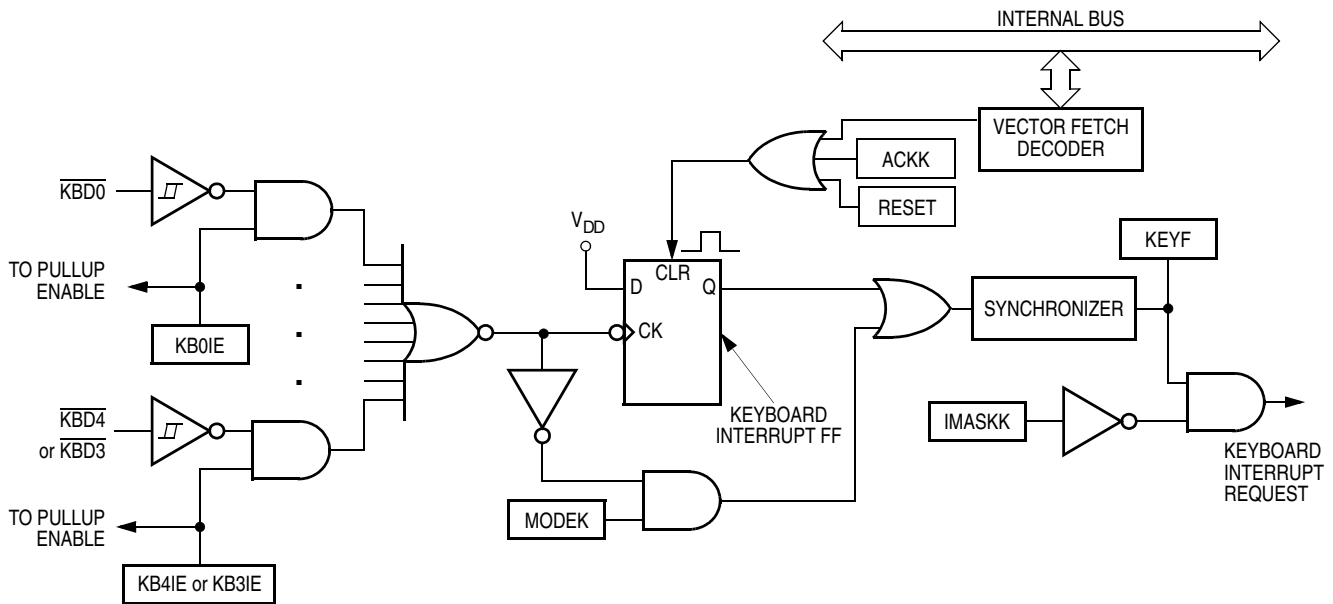

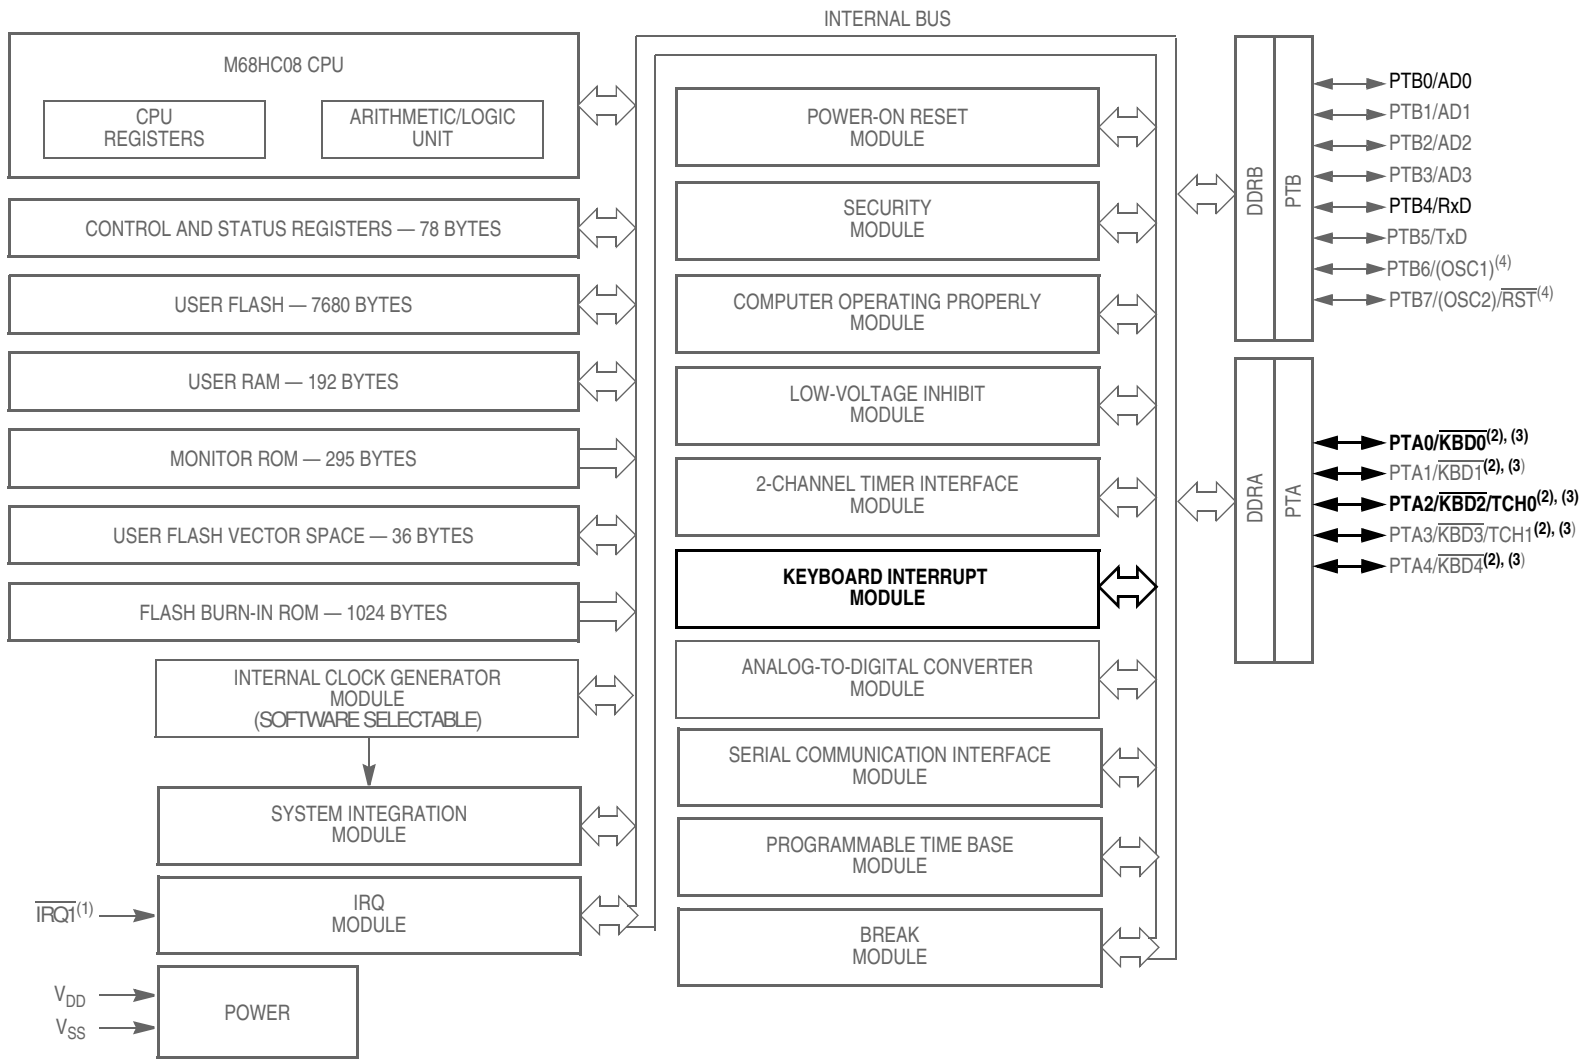

Figure 9-1. Keyboard Module Block Diagram

Notes:

1. Pin contains integrated pullup resistor
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.

Figure 9-3. I/O Register Summary

## 9.3 Functional Description

Writing to the KBIE4–KBIE0 bits in the keyboard interrupt enable register independently enables or disables each port A pin as a keyboard interrupt pin. Enabling a keyboard interrupt pin also enables its internal pullup device. A logic 0 applied to an enabled keyboard interrupt pin latches a keyboard interrupt request.

A keyboard interrupt is latched when one or more keyboard pins goes low after all were high. The MODEK bit in the keyboard status and control register controls the triggering mode of the keyboard interrupt.

- If the keyboard interrupt is edge-sensitive only, a falling edge on a keyboard pin does not latch an interrupt request if another keyboard pin is already low. To prevent losing an interrupt request on one pin because another pin is still low, software can disable the latter pin while it is low.
- If the keyboard interrupt is falling edge- and low level-sensitive, an interrupt request is present as long as any keyboard pin is low.

If the MODEK bit is set, the keyboard interrupt pins are both falling edge- and low level-sensitive, and both of the following actions must occur to clear a keyboard interrupt request:

- Vector fetch or software clear — A vector fetch generates an interrupt acknowledge signal to clear the interrupt request. Software may generate the interrupt acknowledge signal by writing a 1 to the ACKK bit in the keyboard status and control register (KBSCR). The ACKK bit is useful in applications that poll the keyboard interrupt pins and require software to clear the keyboard interrupt request. Writing to the ACKK bit prior to leaving an interrupt service routine also can prevent spurious interrupts due to noise. Setting ACKK does not affect subsequent transitions on the keyboard interrupt pins. A falling edge that occurs after writing to the ACKK bit latches another interrupt request. If the keyboard interrupt mask bit, IMASKK, is clear, the CPU loads the program counter with the vector address at locations \$FFE0 and \$FFE1.
- Return of all enabled keyboard interrupt pins to logic 1 — As long as any enabled keyboard interrupt pin is at logic 0, the keyboard interrupt remains set.

The vector fetch or software clear and the return of all enabled keyboard interrupt pins to logic 1 may occur in any order.

If the MODEK bit is clear, the keyboard interrupt pin is falling edge-sensitive only. With MODEK clear, a vector fetch or software clear immediately clears the keyboard interrupt request.

Reset clears the keyboard interrupt request and the MODEK bit, clearing the interrupt request even if a keyboard interrupt pin stays at logic 0.

## Keyboard Interrupt Module (KBI)

The keyboard flag bit (KEYF) in the keyboard status and control register can be used to see if a pending interrupt exists. The KEYF bit is not affected by the keyboard interrupt mask bit (IMASKK) which makes it useful in applications where polling is preferred.

To determine the logic level on a keyboard interrupt pin, use the data direction register to configure the pin as an input and read the data register.

### NOTE

*Setting a keyboard interrupt enable bit (KBIE<sub>x</sub>) forces the corresponding keyboard interrupt pin to be an input, overriding the data direction register. However, the data direction register bit must be a 0 for software to read the pin.*

## 9.4 Keyboard Initialization

When a keyboard interrupt pin is enabled, the pin may initially be low and cause a false interrupt to occur. A false interrupt on an edge-triggered pin can be acknowledged immediately after enabling the pin. A false interrupt on an edge- and level-triggered interrupt pin must be acknowledged after the pin has been pulled high.

The internal pullup device, the pin capacitance, as well as the external load will factor into the actual amount of time it takes for the pin to pull high. Considering only an internal pullup of 48 k $\Omega$  and pin capacitance of 8 pF, the pullup time will be on the order of 1  $\mu$ s.

To prevent a false interrupt on keyboard initialization:

1. Mask keyboard interrupts by setting the IMASKK bit in the keyboard status and control register.
2. Enable the KBI pins by setting the appropriate KBIE<sub>x</sub> bits in the keyboard interrupt enable register.
3. Write to the ACKK bit in the keyboard status and control register to clear any false interrupts.
4. Clear the IMASKK bit.

Another way to avoid a false interrupt:

1. Configure the keyboard pins as outputs by setting the appropriate DDRA bits in data direction register A.
2. Write 1s to the appropriate port A data register bits.
3. Enable the KBI pins by setting the appropriate KBIE<sub>x</sub> bits in the keyboard interrupt enable register.

## 9.5 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

### 9.5.1 Wait Mode

The keyboard module remains active in wait mode. Clearing the IMASKK bit in the keyboard status and control register enables keyboard interrupt requests to bring the MCU out of wait mode.

### 9.5.2 Stop Mode

The keyboard module remains active in stop mode. Clearing the IMASKK bit in the keyboard status and control register enables keyboard interrupt requests to bring the MCU out of stop mode.

## 9.6 I/O Registers

Two registers control and monitor operation of the keyboard module:

- Keyboard status and control register, KBSCR
- Keyboard interrupt enable register, KBIER

### 9.6.1 Keyboard Status and Control Register

The keyboard status and control register (KBSCR):

- Flags keyboard interrupt requests
- Acknowledges keyboard interrupt requests
- Masks keyboard interrupt requests
- Controls keyboard interrupt triggering sensitivity

Address: \$001A

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	KEYF	0	IMASKK	MODEK
Write:						ACKK		
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

**Figure 9-4. Keyboard Status and Control Register (KBSCR)**

#### Bits 7–4 — Not used

These read-only bits always read as 0s.

#### KEYF — Keyboard Flag Bit

This read-only bit is set when a keyboard interrupt is pending. Reset clears the KEYF bit.

- 1 = Keyboard interrupt pending
- 0 = No keyboard interrupt pending

#### ACKK — Keyboard Acknowledge Bit

Writing a 1 to this write-only bit clears the keyboard interrupt request. ACKK always reads as 0. Reset clears ACKK.

#### IMASKK — Keyboard Interrupt Mask Bit

Writing a 1 to this read/write bit prevents the output of the keyboard interrupt mask from generating interrupt requests. Reset clears the IMASKK bit.

- 1 = Keyboard interrupt requests masked
- 0 = Keyboard interrupt requests not masked

#### MODEK — Keyboard Triggering Sensitivity Bit

This read/write bit controls the triggering sensitivity of the keyboard interrupt pins. Reset clears MODEK.

- 1 = Keyboard interrupt requests on falling edges and low levels
- 0 = Keyboard interrupt requests on falling edges only

### 9.6.2 Keyboard Interrupt Enable Register

The keyboard interrupt enable register (KBIER) enables or disables each port A pin to operate as a keyboard interrupt pin.

**Figure 9-5. Keyboard Interrupt Enable Register (KBIER)**

#### KBIE4–KBIE0 — Keyboard Interrupt Enable Bits

Each of these read/write bits enables the corresponding keyboard interrupt pin to latch interrupt requests. Reset clears the keyboard interrupt enable register.

1 = PAX pin enabled as keyboard interrupt pin

0 = PAX pin not enabled as keyboard interrupt pin

# Chapter 10

## Low-Voltage Inhibit (LVI)

### 10.1 Introduction

This section describes the low-voltage inhibit (LVI) module, which monitors the voltage on the  $V_{DD}$  pin and can force a reset when the  $V_{DD}$  voltage falls below the LVI trip falling voltage,  $V_{TRIPF}$ .

### 10.2 Features

Features of the LVI module include:

- Programmable LVI reset
- Programmable power consumption
- Selectable LVI trip voltage
- Programmable stop mode operation

### 10.3 Functional Description

Figure 10-1 shows the structure of the LVI module. LVISTOP, LVIPWRD, LVI5OR3, and LVIRSTD are user selectable options found in the configuration register (CONFIG1). See [Chapter 4 Configuration Register \(CONFIG\)](#).

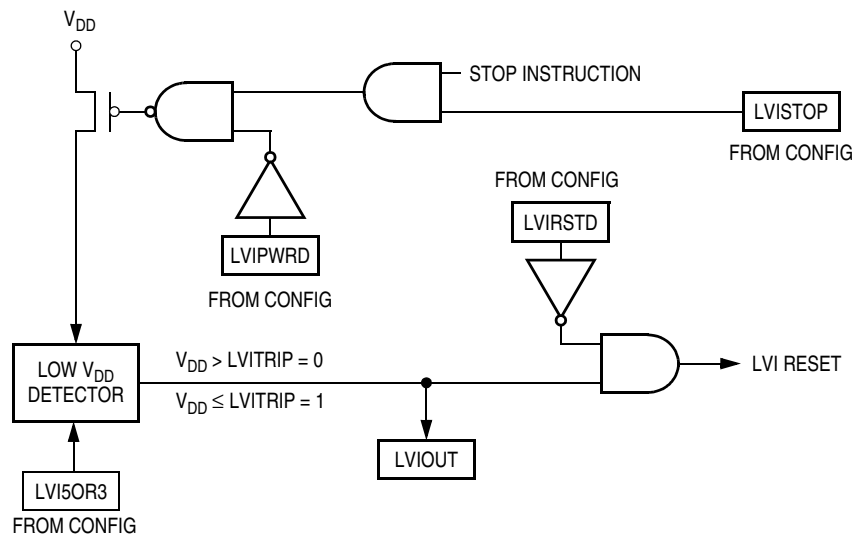

Figure 10-1. LVI Module Block Diagram

The LVI is enabled out of reset. The LVI module contains a bandgap reference circuit and comparator. Clearing the LVI power disable bit, LVIPWRD, enables the LVI to monitor  $V_{DD}$  voltage. Clearing the LVI reset disable bit, LVIRSTD, enables the LVI module to generate a reset when  $V_{DD}$  falls below a voltage,  $V_{TRIPF}$ . Setting the LVI enable in stop mode bit, LVISTOP, enables the LVI to operate in stop mode.

## Low-Voltage Inhibit (LVI)

Setting the LVI 5-V or 3-V trip point bit, LVI5OR3, enables the trip point voltage,  $V_{TRIPF}$ , to be configured for 5-V operation. Clearing the LVI5OR3 bit enables the trip point voltage,  $V_{TRIPF}$ , to be configured for 3-V operation. The actual trip thresholds are specified in [17.5 5.0-Vdc DC Electrical Characteristics](#) and .

### NOTE

*After a power-on reset, the LVI's default mode of operation is 3 volts. If a 5-V system is used, the user must set the LVI5OR3 bit to raise the trip point to 5-V operation.*

*If the user requires 5-V mode and sets the LVI5OR3 bit after power-on reset while the  $V_{DD}$  supply is not above the  $V_{TRIPR}$  for 5-V mode, the MCU will immediately go into reset. The next time the LVI releases the reset, the supply will be above the  $V_{TRIPR}$  for 5-V mode.*

Once an LVI reset occurs, the MCU remains in reset until  $V_{DD}$  rises above a voltage,  $V_{TRIPR}$ , which causes the MCU to exit reset. See [Chapter 13 System Integration Module \(SIM\)](#) for the reset recovery sequence.

The output of the comparator controls the state of the LVIOOUT flag in the LVI status register (LVISR) and can be used for polling LVI operation when the LVI reset is disabled.

### 10.3.1 Polled LVI Operation

In applications that can operate at  $V_{DD}$  levels below the  $V_{TRIPF}$  level, software can monitor  $V_{DD}$  by polling the LVIOOUT bit. In the configuration register, the LVIPWRD bit must be at 0 to enable the LVI module, and the LVIRSTD bit must be at 1 to disable LVI resets.

### 10.3.2 Forced Reset Operation

In applications that require  $V_{DD}$  to remain above the  $V_{TRIPF}$  level, enabling LVI resets allows the LVI module to reset the MCU when  $V_{DD}$  falls below the  $V_{TRIPF}$  level. In the configuration register, the LVIPWRD and LVIRSTD bits must be at 0 to enable the LVI module and to enable LVI resets.

### 10.3.3 Voltage Hysteresis Protection

Once the LVI has triggered (by having  $V_{DD}$  fall below  $V_{TRIPF}$ ), the LVI will maintain a reset condition until  $V_{DD}$  rises above the rising trip point voltage,  $V_{TRIPR}$ . This prevents a condition in which the MCU is continually entering and exiting reset if  $V_{DD}$  is approximately equal to  $V_{TRIPF}$ .  $V_{TRIPR}$  is greater than  $V_{TRIPF}$  by the hysteresis voltage,  $V_{HYS}$ .

### 10.3.4 LVI Trip Selection

The LVI5OR3 bit in the configuration register selects whether the LVI is configured for 5-V or 3-V protection.

### NOTE

*The microcontroller is guaranteed to operate at a minimum supply voltage. The trip point ( $V_{TRIPF}$  [5 V] or  $V_{TRIPF}$  [3 V]) may be lower than this. See [17.5 5.0-Vdc DC Electrical Characteristics](#) and for the actual trip point voltages.*

## 10.4 LVI Status Register

The LVI status register (LVISR) indicates if the  $V_{DD}$  voltage was detected below the  $V_{TRIPF}$  level while LVI resets have been disabled.

**Figure 10-2. LVI Status Register (LVISR)**

### LVIOUT — LVI Output Bit

This read-only flag becomes set when the  $V_{DD}$  voltage falls below the  $V_{TRIPF}$  trip voltage and is cleared when  $V_{DD}$  voltage rises above  $V_{TRIPR}$ . The difference in these threshold levels results in a hysteresis that prevents oscillation into and out of reset. (See [Table 10-1](#).) Reset clears the LVIOUT bit.

**Table 10-1. LVIOUT Bit Indication**

$V_{DD}$	LVIOUT
$V_{DD} > V_{TRIPR}$	0
$V_{DD} < V_{TRIPF}$	1
$V_{TRIPF} < V_{DD} < V_{TRIPR}$	Previous value

## 10.5 LVI Interrupts

The LVI module does not generate interrupt requests.

## 10.6 Low-Power Modes

The STOP and WAIT instructions put the MCU in low power-consumption standby modes.

### 10.6.1 Wait Mode

If enabled, the LVI module remains active in wait mode. If enabled to generate resets, the LVI module can generate a reset and bring the MCU out of wait mode.

### 10.6.2 Stop Mode

When the LVIPWRD bit in the configuration register is cleared and the LVISTOP bit in the configuration register is set, the LVI module remains active in stop mode. If enabled to generate resets, the LVI module can generate a reset and bring the MCU out of stop mode.

# Chapter 11

## Input/Output (I/O) Ports (PORTS)

### 11.1 Introduction

Thirteen bidirectional input/output (I/O) pins form two parallel ports in the 16-pin plastic dual in-line package (PDIP) and small outline integrated circuit (SOIC) package in the MC68HC908KX8 part. All I/O pins are programmable as inputs or outputs. Port A has software selectable pullup resistors if the port is used as a general-function input port.

**NOTE**

*Connect any unused I/O pins to an appropriate logic level, either  $V_{DD}$  or  $V_{SS}$ . Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.*

See [Figure 11-1](#) for a summary of the I/O port registers.

Addr.	Register Name		Bit 7	6	5	4	3	2	1	Bit 0

**Figure 11-1. I/O Port Register Summary**

## 11.2 Port A

Port A is a 5-bit special function port on the MC68HC908KX8 that shares all of its pins with the keyboard interrupt module (KBI) and the 2-channel timer. Port A contains software programmable pullup resistors enabled when a port pin is used as a general-function input. Port A pins are also high-current port pins with 15-mA source/15-mA sink capabilities.

### 11.2.1 Port A Data Register

The port A data register (PTA) contains a data latch for each of the five port A pins.

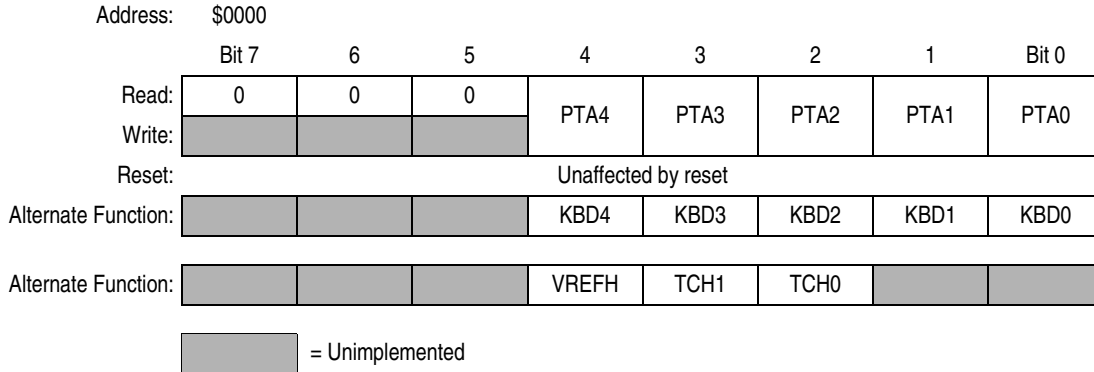

Figure 11-2. Port A Data Register (PTA)

#### PTA4–PTA0 — Port A Data Bits

These read/write bits are software programmable. Data direction of each port A pin is under the control of the corresponding bit in data direction register A. Reset has no effect on port A data.

#### KBD4–KBD0 — Keyboard Wakeup Bits

The keyboard interrupt enable bits, KBIE4–KBIE0, in the keyboard interrupt control register, enable the port A pins as external interrupt pins. See [Chapter 9 Keyboard Interrupt Module \(KBI\)](#).

#### TCH1 and TCH0 — Timer Channel I/O Bits

The PTA3/ $\overline{\text{KBD3}}$ /TCH1 and PTA2/ $\overline{\text{KBD2}}$ /TCH0 pins are the TIM input capture/output compare pins. The edge/level select bits, ELSxB and ELSxA, determine whether the pins are timer channel I/O pins or general-purpose I/O pins. See [Chapter 9 Keyboard Interrupt Module \(KBI\)](#).

### 11.2.2 Data Direction Register A

Data direction register A (DDRA) determines whether each port A pin is an input or an output. Writing a 1 to a DDRA bit enables the output buffer for the corresponding port A pin; a 0 disables the output buffer.

Figure 11-3. Data Direction Register A (DDRA)

### DDRA4–DDRA0 — Data Direction Register A Bits

These read/write bits control port A data direction. Reset clears DDRA4–DDRA0, configuring all port A pins as inputs.

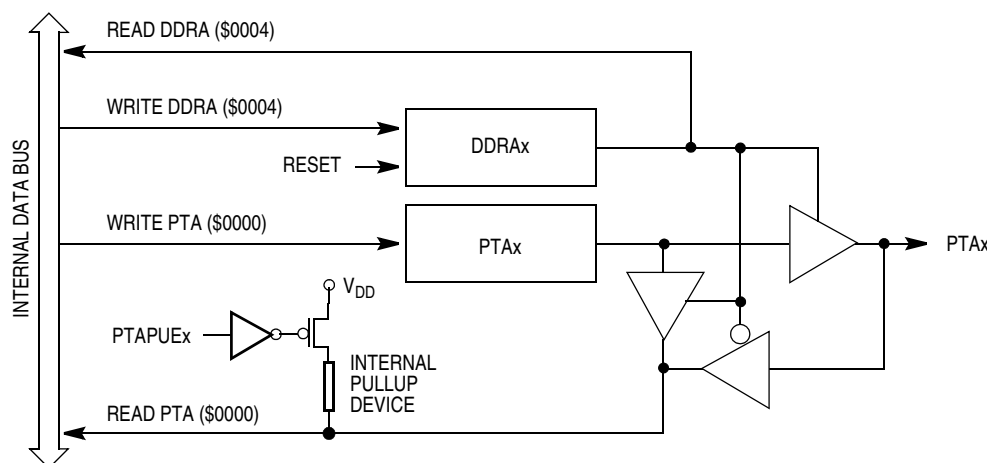

1 = Corresponding port A pin configured as output

0 = Corresponding port A pin configured as input

#### NOTE

*Avoid glitches on port A pins by writing to the port A data register before changing data direction register A bits from 0 to 1.*

Figure 11-4 shows the port A I/O logic.

**Figure 11-4. Port A I/O Circuit**

When bit DDRA<sub>x</sub> is a 1, reading address \$0000 reads the PTA<sub>x</sub> data latch. When bit DDRA<sub>x</sub> is a 0, reading address \$0000 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. Table 11-1 summarizes the operation of the port A pins.

**Table 11-1. Port A Pin Functions**

PTAPUE Bit	DDRA Bit	PTA Bit	I/O Pin Mode	Accesses to DDRA		
				Read/Write	Read	Write
1	0	X	Input, V <sub>DD</sub> <sup>(1)</sup>	DDRA4–DDRA0	Pin	PTA4–PTA0 <sup>(2)</sup>
0	0	X	Input, Hi-Z	DDRA4–DDRA0	Pin	PTA4–PTA0 <sup>(3)</sup>
X	1	X	Output	DDRA4–DDRA0	PTA4–PTA0	PTA4–PTA0

X = Don't care

Hi-Z = High impedance

1. I/O pin pulled up to V<sub>DD</sub> by internal pullup device
2. Writing affects data register, but does not affect input.

### 11.2.3 Port A Input Pullup Enable Register

The port A input pullup enable register (PTAPUE) contains a software configurable pullup device for each of the five port A pins. Each bit is individually configurable and requires that the data direction register, DDRA, bit be configured as an input. Each pullup is automatically disabled when a port bit's DDRA is configured for output mode.

## Input/Output (I/O) Ports (PORTS)

Address: \$000D

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	PTAPUE4	PTAPUE3	PTAPUE2	PTAPUE1	PTAPUE0
Write:								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

**Figure 11-5. Port A Input Pullup Enable Register (PTAPUE)**

### PTAPUE4–PTAPUE0 — Port A Input Pullup Enable Bits

These writable bits are software programmable to enable pullup devices on an input port bit.

1 = Corresponding port A pin configured to have internal pullup

0 = Corresponding port A pin has internal pullup disconnected

## 11.3 Port B

Port B is an 8-bit special-function port that shares four of its pins with the analog-to-digital converter module (ADC), two with the serial communication interface module (SCI) and two with an optional external clock source.

### 11.3.1 Port B Data Register

The port B data register (PTB) contains a data latch for each of the eight port B pins.

Address: \$0001

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	PTB7	PTB6	PTB5	PTB4	PTB3	PTB2	PTB1	PTB0
Write:								
Reset:	Unaffected by reset							
Alternate Function:	OSC2	OSC1	TxD	RxD	AD3	AD2	AD1	AD0

**Figure 11-6. Port B Data Register (PTB)**

### PTB7–PTB0 — Port B Data Bits

These read/write bits are software-programmable. Data direction of each port B pin is under the control of the corresponding bit in data direction register B. Reset has no effect on port B data.

### OSC2 and OSC1 — OSC2 and OSC1 Bits

Under software control, PTB7 and PTB6 can be configured as external clock inputs and outputs. PTB7 will become an output clock, OSC2, if selected in the configuration registers and enabled in the ICG registers. PTB6 will become an external input clock source, OSC1, if selected in the configuration registers and enabled in the ICG registers. See [Chapter 7 Internal Clock Generator Module \(ICG\)](#) and [Chapter 4 Configuration Register \(CONFIG\)](#).

### RxD — SCI Receive Data Input Bit

The PTB1/RxD pin is the receive data input for the SCI module. When the enable SCI bit, ENSCI, is clear, the SCI module is disabled, and the PTB1/RxD pin is available for general-purpose I/O. See [Chapter 12 Serial Communications Interface Module \(SCI\)](#).

### TxD — SCI Transmit Data Output Bit

The PTB0/TxD pin is the transmit data output for the SCI module. When the enable SCI bit, ENSCI, is clear, the SCI module is disabled, and the PTB0/TxD pin is available for general-purpose I/O. See [Chapter 12 Serial Communications Interface Module \(SCI\)](#).

### AD3–AD0 — Analog-to-Digital Input Bits

AD3–AD0 are pins used for the input channels to the analog-to-digital converter (ADC) module. The channel select bits in the ADC status and control register define which port B pin will be used as an ADC input and overrides any control from the port I/O logic by forcing that pin as the input to the analog circuitry. See [Chapter 3 Analog-to-Digital Converter \(ADC\)](#).

## 11.3.2 Data Direction Register B

Data direction register B (DDRB) determines whether each port B pin is an input or an output. Writing a 1 to a DDRB bit enables the output buffer for the corresponding port B pin; a 0 disables the output buffer.

Figure 11-7. Data Direction Register B (DDRB)

### DDRB7–DDRB0 — Data Direction Register B Bits

These read/write bits control port B data direction. Reset clears DDRB7–DDRB0, configuring all port B pins as inputs.

1 = Corresponding port B pin configured as output

0 = Corresponding port B pin configured as input

#### NOTE

*Avoid glitches on port B pins by writing to the port B data register before changing data direction register B bits from 0 to 1.*

Figure 11-8 shows the port B I/O logic.

Figure 11-8. Port B I/O Circuit

## Input/Output (I/O) Ports (PORTS)

When bit DDRBx is a 1, reading address \$0001 reads the PTBx data latch. When bit DDRBx is a 0, reading address \$0001 reads the voltage level on the pin. The data latch can always be written, regardless of the state of its data direction bit. [Table 11-2](#) summarizes the operation of the port B pins.

**Table 11-2. Port B Pin Functions**

DDR B Bit	PTB Bit	I/O Pin Mode	Accesses to DDRB	Accesses to PTB	
			Read/Write	Read	Write
0	X	Input, Hi-Z	DDR B7–DDR B0	Pin	PTB7–PTB0 <sup>(1)</sup>
1	X	Output	DDR B7–DDR B0	PTB7–PTB0	PTB7–PTB0

X = Don't care

Hi-Z = High impedance

1. Writing affects data register, but does not affect input.

# Chapter 12

## Serial Communications Interface Module (SCI)

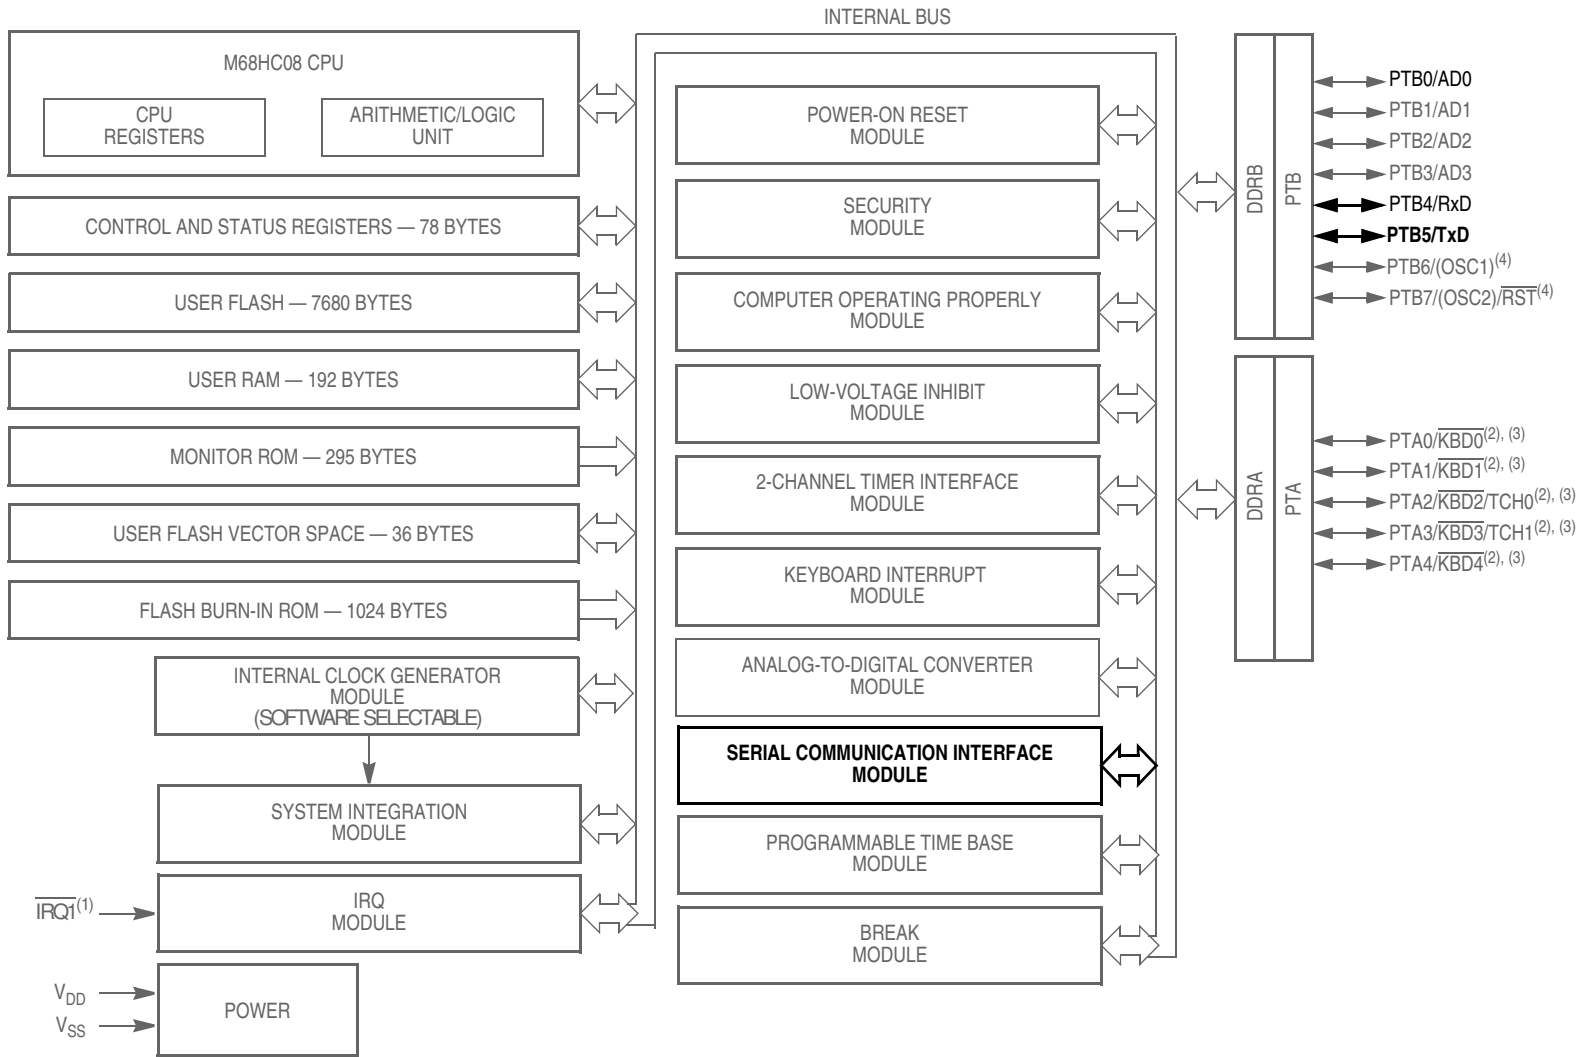

### 12.1 Introduction

The serial communications interface (SCI) allows asynchronous communications with peripheral devices and other microcontroller unit (MCU).

### 12.2 Features

The SCI module's features include:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- Choice of baud rate clock source:
  - Internal bus clock
  - CGMXCLK
- 32 programmable baud rates
- Programmable 8-bit or 9-bit character length
- Separately enabled transmitter and receiver
- Separate receiver and transmitter central processor unit (CPU) interrupt requests
- Programmable transmitter output polarity
- Two receiver wakeup methods:
  - Idle line wakeup
  - Address mark wakeup
- Interrupt-driven operation with eight interrupt flags:
  - Transmitter empty
  - Transmission complete
  - Receiver full
  - Idle receiver input
  - Receiver overrun
  - Noise error
  - Framing error
  - Parity error
- Receiver framing error detection
- Hardware parity checking
- 1/16 bit-time noise detection

Notes:

1. Pin contains integrated pullup resistor
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.

Figure 12-1. Block Diagram Highlighting SCI Block and Pins

## 12.3 Pin Name Conventions

The generic names of the SCI input/output (I/O) pins are:

- RxD, receive data
- TxD, transmit data

SCI I/O lines are implemented by sharing parallel I/O port pins. The full name of an SCI input or output reflects the name of the shared port pin. [Table 12-1](#) shows the full names and the generic names of the SCI I/O pins. The generic pin names appear in the text of this section.

**Table 12-1. Pin Name Conventions**

Generic Pin Names	RxD	TxD
Full Pin Names	PTB4/RxD	PTB5/TxD

## 12.4 Functional Description

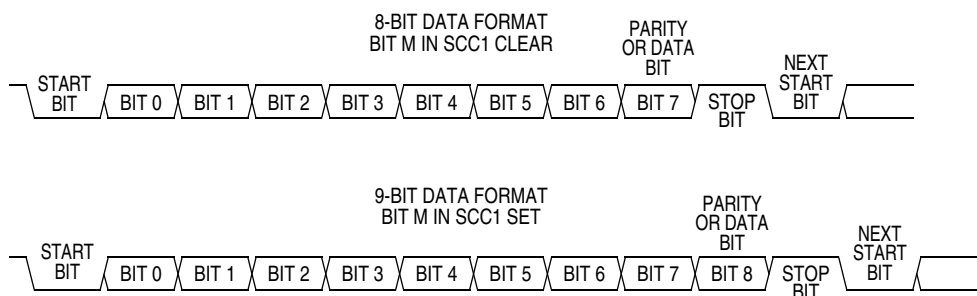

[Figure 12-3](#) shows the structure of the SCI module. The SCI allows full-duplex, asynchronous, NRZ serial communication between the MCU and remote devices, including other MCUs. The transmitter and receiver of the SCI operate independently, although they use the same baud rate generator.

The source of the baud rate clock is determined by the configuration register 2 bit, SCIBDSRC. If SCIBDSRC is set then the source of the SCI is the internal data bus clock. If SCIBDSRC is cleared, the source of the SCI is oscillator output CGMXCLK.

During normal operation, the CPU monitors the status of the SCI, writes the data to be transmitted, and processes received data.

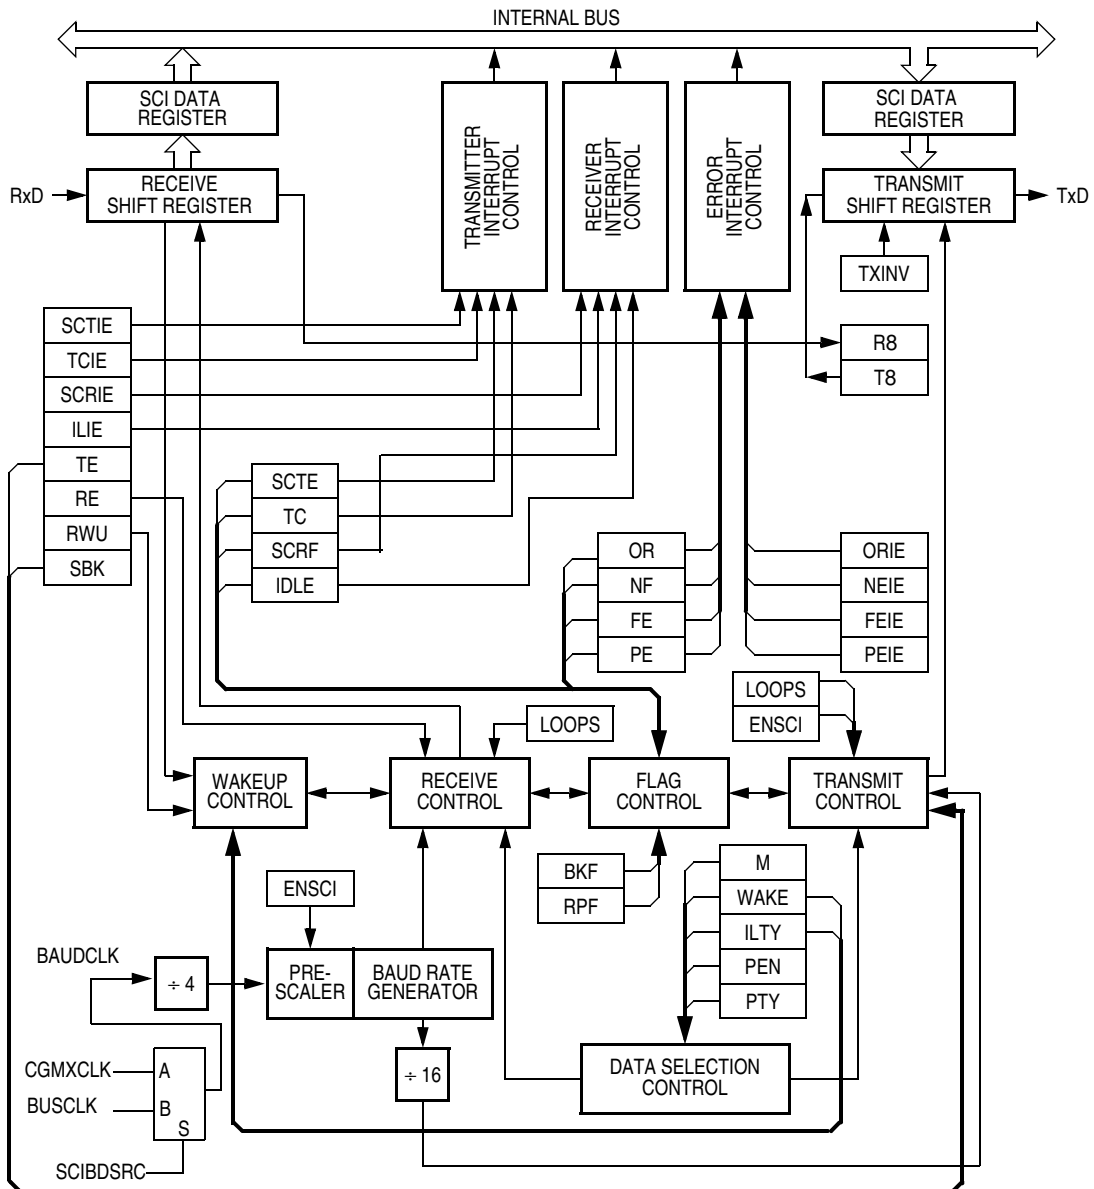

### 12.4.1 Data Format

The SCI uses the standard non-return-to-zero mark/space data format illustrated in [Figure 12-2](#).

**Figure 12-2. SCI Data Formats**

Figure 12-4. SCI I/O Register Summary

## 12.4.2 Transmitter

Figure 12-5 shows the structure of the SCI transmitter.

### 12.4.2.1 Character Length

The transmitter can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCC1) determines character length. When transmitting 9-bit data, bit T8 in SCI control register 3 (SCC3) is the ninth bit (bit 8).

### 12.4.2.2 Character Transmission

During an SCI transmission, the transmit shift register shifts a character out to the TxD pin. The SCI data register (SCDR) is the write-only buffer between the internal data bus and the transmit shift register. To initiate an SCI transmission:

1. Enable the SCI by writing a 1 to the enable SCI bit (ENSCI) in SCI control register 1 (SCC1).
2. Enable the transmitter by writing a 1 to the transmitter enable bit (TE) in SCI control register 2 (SCC2).
3. Clear the SCI transmitter empty bit by first reading SCI status register 1 (SCS1) and then writing to the SCDR.
4. Repeat step 3 for each subsequent transmission.

**Figure 12-5. SCI Transmitter Break Characters**

At the start of a transmission, transmitter control logic automatically loads the transmit shift register with a preamble of logic 1s. After the preamble shifts out, control logic transfers the SCDR data into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

The SCI transmitter empty bit, SCTE, in SCS1 becomes set when the SCDR transfers a byte to the transmit shift register. The SCTE bit indicates that the SCDR can accept new data from the internal data bus. If the SCI transmit interrupt enable bit, SCTIE, in SCC2 is also set, the SCTE bit generates a transmitter CPU interrupt request.

When the transmit shift register is not transmitting a character, the TxD pin goes to the idle condition, logic 1. If at any time software clears the ENSCI bit in SCI control register 1 (SCC1), the transmitter and receiver relinquish control of the port B pins.

Writing a 1 to the send break bit, SBK, in SCC2 loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character length depends on the M bit in SCC1. As long as SBK is at 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last

break character and then transmits at least one 1. The automatic 1 at the end of a break character guarantees the recognition of the start bit of the next character.

#### 12.4.2.3 Break Characters

The SCI recognizes a break character when a start bit is followed by eight or nine 0 data bits and a 0 where the stop bit should be. Receiving a break character has these effects on SCI registers:

- Sets the framing error bit (FE) in SCS1
- Sets the SCI receiver full bit (SCRF) in SCS1
- Clears the SCI data register (SCDR)
- Clears the R8 bit in SCC3
- Sets the break flag bit (BKF) in SCS2
- May set the overrun (OR), noise flag (NF), parity error (PE), or reception-in-progress flag (RPF) bits

#### 12.4.2.4 Idle Characters

An idle character contains all 1s and has no start, stop, or parity bit. Idle character length depends on the M bit in SCC1. The preamble is a synchronizing idle character that begins every transmission.

If the TE bit is cleared during a transmission, the TxD pin becomes idle after completion of the transmission in progress. Clearing and then setting the TE bit during a transmission queues an idle character to be sent after the character currently being transmitted.

#### NOTE

*When queueing an idle character, return the TE bit to 1 before the stop bit of the current character shifts out to the TxD pin. Setting TE after the stop bit appears on TxD causes data previously written to the SCDR to be lost.*

*A good time to toggle the TE bit for a queued idle character is when the SCTE bit becomes set and just before writing the next byte to the SCDR.*

#### 12.4.2.5 Inversion of Transmitted Output

The transmit inversion bit (TXINV) in SCI control register 1 (SCC1) reverses the polarity of transmitted data. All transmitted values, including idle, break, start, and stop bits, are inverted when TXINV is at 1. See [12.7.1 SCI Control Register 1](#).

#### 12.4.2.6 Transmitter Interrupts

These conditions can generate CPU interrupt requests from the SCI transmitter:

- SCI transmitter empty (SCTE) — The SCTE bit in SCS1 indicates that the SCDR has transferred a character to the transmit shift register. SCTE can generate a transmitter CPU interrupt request. Setting the SCI transmit interrupt enable bit, SCTIE, in SCC2 enables the SCTE bit to generate transmitter CPU interrupt requests.
- Transmission complete (TC) — The TC bit in SCS1 indicates that the transmit shift register and the SCDR are empty and that no break or idle character has been generated. The transmission complete interrupt enable bit, TCIE, in SCC2 enables the TC bit to generate transmitter CPU interrupt requests.

### 12.4.3 Receiver

Figure 12-6 shows the structure of the SCI receiver.

Figure 12-6. SCI Receiver Block Diagram

### 12.4.3.1 Character Length

The receiver can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCC1) determines character length. When receiving 9-bit data, bit R8 in SCI control register 2 (SCC2) is the ninth bit (bit 8). When receiving 8-bit data, bit R8 is a copy of the eighth bit (bit 7).

### 12.4.3.2 Character Reception

During an SCI reception, the receive shift register shifts characters in from the RxD pin. The SCI data register (SCDR) is the read-only buffer between the internal data bus and the receive shift register.

After a complete character shifts into the receive shift register, the data portion of the character transfers to the SCDR. The SCI receiver full bit, SCRF, in SCI status register 1 (SCS1) becomes set, indicating that the received byte can be read. If the SCI receive interrupt enable bit, SCRIE, in SCC2 is also set, the SCRF bit generates a receiver CPU interrupt request.

### 12.4.3.3 Data Sampling

The receiver samples the RxD pin at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch, the RT clock is resynchronized at these times (see [Figure 12-7](#)):

- After every start bit
- After the receiver detects a data bit change from 1 to 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid 0)

To locate the start bit, data recovery logic does an asynchronous search for a 0 preceded by three 1s. When the falling edge of a possible start bit occurs, the RT clock begins to count to 16.

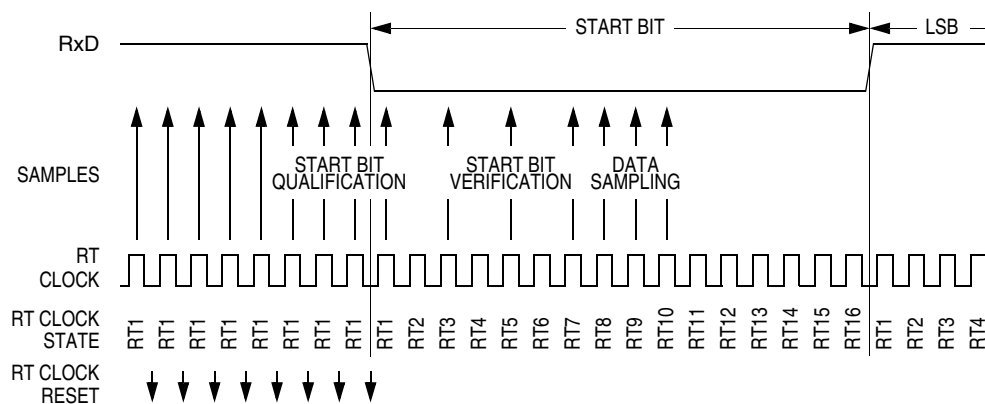

Figure 12-7. Receiver Data Sampling

To verify the start bit and to detect noise, data recovery logic takes samples at RT3, RT5, and RT7.

Table 12-2 summarizes the results of the start bit verification samples.

**Table 12-2. Start Bit Verification**

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
110	No	0
111	No	0

If start bit verification is not successful, the RT clock is reset and a new search for a start bit begins.

To determine the value of a data bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. Table 12-3 summarizes the results of the data bit samples.

**Table 12-3. Data Bit Recovery**

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

**NOTE**

*The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit.*

To verify a stop bit and to detect noise, recovery logic takes samples at RT8, RT9, and RT10. [Table 12-4](#) summarizes the results of the stop bit samples.

**Table 12-4. Stop Bit Recovery**

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

#### 12.4.3.4 Framing Errors

If the data recovery logic does not detect a 1 where the stop bit should be in an incoming character, it sets the framing error bit, FE, in SCS1. A break character also sets the FE bit because a break character has no stop bit. The FE bit is set at the same time that the SCRF bit is set.

#### 12.4.3.5 Baud Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples to fall outside the actual stop bit. Then a noise error occurs. If more than one of the samples is outside the stop bit, a framing error occurs. In most applications, the baud rate tolerance is much more than the degree of misalignment that is likely to occur.

As the receiver samples an incoming character, it resynchronizes the RT clock on any valid falling edge within the character. Resynchronization within characters corrects misalignments between transmitter bit times and receiver bit times.

#### Slow Data Tolerance

[Figure 12-8](#) shows how much a slow received character can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT1 instead of RT8 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

**Figure 12-8. Slow Data**

For an 8-bit character, data sampling of the stop bit takes the receiver  $9 \text{ bit times} \times 16 \text{ RT cycles} + 10 \text{ RT cycles} = 154 \text{ RT cycles}$ .

With the misaligned character shown in [Figure 12-8](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 9 bit times  $\times$  16 RT cycles + 3 RT cycles = 147 RT cycles. The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit character with no errors is

$$\left| \frac{154 - 147}{154} \right| \times 100 = 4.54\%$$

For a 9-bit character, data sampling of the stop bit takes the receiver 10 bit times  $\times$  16 RT cycles + 10 RT cycles = 170 RT cycles.

With the misaligned character shown in [Figure 12-8](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 10 bit times  $\times$  16 RT cycles + 3 RT cycles = 163 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is

$$\left| \frac{170 - 163}{170} \right| \times 100 = 4.12\%$$

### Fast Data Tolerance

[Figure 12-9](#) shows how much a fast received character can be misaligned without causing a noise error or a framing error. The fast stop bit ends at RT10 instead of RT16 but is still there for the stop bit data samples at RT8, RT9, and RT10.

**Figure 12-9. Fast Data**

For an 8-bit character, data sampling of the stop bit takes the receiver 9 bit times  $\times$  16 RT cycles + 10 RT cycles = 154 RT cycles.

With the misaligned character shown in [Figure 12-9](#), the receiver counts 154 RT cycles at the point when the count of the transmitting device is 10 bit times  $\times$  16 RT cycles = 160 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is

$$\left| \frac{154 - 160}{154} \right| \times 100 = 3.90\%$$

For a 9-bit character, data sampling of the stop bit takes the receiver 10 bit times  $\times$  16 RT cycles + 10 RT cycles = 170 RT cycles.

With the misaligned character shown in [Figure 12-9](#), the receiver counts 170 RT cycles at the point when the count of the transmitting device is 11 bit times  $\times$  16 RT cycles = 176 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is

$$\left| \frac{170 - 176}{170} \right| \times 100 = 3.53\%.$$

#### 12.4.3.6 Receiver Wakeup

So that the MCU can ignore transmissions intended only for other receivers in multiple-receiver systems, the receiver can be put into a standby state. Setting the receiver wakeup bit, RWU, in SCC2 puts the receiver into a standby state during which receiver interrupts are disabled.

Depending on the state of the WAKE bit in SCC1, either of two conditions on the RxD pin can bring the receiver out of the standby state:

1. Address mark — An address mark is a 1 in the most significant bit position of a received character. When the WAKE bit is set, an address mark wakes the receiver from the standby state by clearing the RWU bit. The address mark also sets the SCI receiver full bit, SCRF. Software can then compare the character containing the address mark to the user-defined address of the receiver. If they are the same, the receiver remains awake and processes the characters that follow. If they are not the same, software can set the RWU bit and put the receiver back into the standby state.
2. Idle input line condition — When the WAKE bit is clear, an idle character on the RxD pin wakes the receiver from the standby state by clearing the RWU bit. The idle character that wakes the receiver does not set the receiver idle bit, IDLE, or the SCI receiver full bit, SCRF. The idle line type bit, ILTY, determines whether the receiver begins counting 1s as idle character bits after the start bit or after the stop bit.

#### NOTE

*With the WAKE bit clear, setting the RWU bit after the RxD pin has been idle may cause the receiver to wake up immediately.*

#### 12.4.3.7 Receiver Interrupts

These sources can generate CPU interrupt requests from the SCI receiver:

- SCI receiver full (SCRF) — The SCRF bit in SCS1 indicates that the receive shift register has transferred a character to the SCDR. SCRF can generate a receiver CPU interrupt request. Setting the SCI receive interrupt enable bit, SCRIE, in SCC2 enables the SCRF bit to generate receiver CPU interrupts.
- Idle input (IDLE) — The IDLE bit in SCS1 indicates that 10 or 11 consecutive 1s shifted in from the RxD pin. The idle line interrupt enable bit, ILIE, in SCC2 enables the IDLE bit to generate CPU interrupt requests.

#### 12.4.3.8 Error Interrupts

These receiver error flags in SCS1 can generate CPU interrupt requests:

- Receiver overrun (OR) — The OR bit indicates that the receive shift register shifted in a new character before the previous character was read from the SCDR. The previous character remains in the SCDR, and the new character is lost. The overrun interrupt enable bit, ORIE, in SCC3 enables OR to generate SCI error CPU interrupt requests.

## Serial Communications Interface Module (SCI)

- Noise flag (NF) — The NF bit is set when the SCI detects noise on incoming data or break characters, including start, data, and stop bits. The noise error interrupt enable bit, NEIE, in SCC3 enables NF to generate SCI error CPU interrupt requests.
- Framing error (FE) — The FE bit in SCS1 is set when a 0 occurs where the receiver expects a stop bit. The framing error interrupt enable bit, FEIE, in SCC3 enables FE to generate SCI error CPU interrupt requests.
- Parity error (PE) — The PE bit in SCS1 is set when the SCI detects a parity error in incoming data. The parity error interrupt enable bit, PEIE, in SCC3 enables PE to generate SCI error CPU interrupt requests.

## 12.5 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power- consumption standby modes.

### 12.5.1 Wait Mode

The SCI module remains active in wait mode. Any enabled CPU interrupt request from the SCI module can bring the MCU out of wait mode.

If SCI module functions are not required during wait mode, reduce power consumption by disabling the module before executing the WAIT instruction.

### 12.5.2 Stop Mode

The SCI module is inactive in stop mode. The STOP instruction does not affect SCI register states. SCI module operation resumes after the MCU exits stop mode.

Because the internal clock is inactive during stop mode, entering stop mode during an SCI transmission or reception results in invalid data.

## 12.6 I/O Signals

Port B shares two of its pins with the SCI module. The two SCI I/O pins are:

- TxD — Transmit data
- RxD — Receive data

### 12.6.1 TxD (Transmit Data)

The TxD pin is the serial data output from the SCI transmitter. The SCI shares the TxD pin with port B. When the SCI is enabled, the TxD pin is an output regardless of the state of the DDRB5 bit in data direction register B (DDRB).

### 12.6.2 RxD (Receive Data)

The RxD pin is the serial data input to the SCI receiver. The SCI shares the RxD pin with port B. When the SCI is enabled, the RxD pin is an input regardless of the state of the DDRB4 bit in data direction register B (DDRB).

## 12.7 I/O Registers

These I/O registers control and monitor SCI operation:

- SCI control register 1 (SCC1)
- SCI control register 2 (SCC2)
- SCI control register 3 (SCC3)
- SCI status register 1 (SCS1)
- SCI status register 2 (SCS2)
- SCI data register (SCDR)
- SCI baud rate register (SCBR)

### 12.7.1 SCI Control Register 1

SCI control register 1 (SCC1):

- Enables loop mode operation
- Enables the SCI
- Controls output polarity
- Controls character length
- Controls SCI wakeup method
- Controls idle character detection
- Enables parity function
- Controls parity type

Address:	\$0013							
	Bit 7	6	5	4	3	2	1	Bit 0
Read:	LOOPS	ENSCI	TXINV	M	WAKE	ILTY	PEN	PTY
Write:								
Reset:	0	0	0	0	0	0	0	0

**Figure 12-10. SCI Control Register 1 (SCC1)**

#### LOOPS — Loop Mode Select Bit

This read/write bit enables loop mode operation. In loop mode the RxD pin is disconnected from the SCI, and the transmitter output goes into the receiver input. Both the transmitter and the receiver must be enabled to use loop mode. Reset clears the LOOPS bit.

1 = Loop mode enabled

0 = Normal operation enabled

#### ENSCI — Enable SCI Bit

This read/write bit enables the SCI and the SCI baud rate generator. Clearing ENSCI sets the SCTE and TC bits in SCI status register 1 and disables transmitter interrupts. Reset clears the ENSCI bit.

1 = SCI enabled

0 = SCI disabled

**TXINV — Transmit Inversion Bit**

This read/write bit reverses the polarity of transmitted data. Reset clears the TXINV bit.

- 1 = Transmitter output inverted
- 0 = Transmitter output not inverted

**NOTE**

*Setting the TXINV bit inverts all transmitted values, including idle, break, start, and stop bits.*

**M — Mode (Character Length) Bit**

This read/write bit determines whether SCI characters are eight or nine bits long. (See [Table 12-5](#).)

The ninth bit can serve as an extra stop bit, as a receiver wakeup signal, or as a parity bit. Reset clears the M bit.

- 1 = 9-bit SCI characters
- 0 = 8-bit SCI characters

**WAKE — Wakeup Condition Bit**

This read/write bit determines which condition wakes up the SCI: a 1 (address mark) in the most significant bit position of a received character or an idle condition on the RxD pin. Reset clears the WAKE bit.

- 1 = Address mark wakeup
- 0 = Idle line wakeup

**ILTY — Idle Line Type Bit**

This read/write bit determines when the SCI starts counting 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. Reset clears the ILTY bit.

- 1 = Idle character bit count begins after stop bit.
- 0 = Idle character bit count begins after start bit.

**PEN — Parity Enable Bit**

This read/write bit enables the SCI parity function. (See [Table 12-5](#).) When enabled, the parity function inserts a parity bit in the most significant bit position. (See [Figure 12-2](#).) Reset clears the PEN bit.

- 1 = Parity function enabled
- 0 = Parity function disabled

**PTY — Parity Bit**

This read/write bit determines whether the SCI generates and checks for odd parity or even parity. (See [Table 12-5](#).) Reset clears the PTY bit.

- 1 = Odd parity
- 0 = Even parity

**NOTE**

*Changing the PTY bit in the middle of a transmission or reception can generate a parity error.*

Table 12-5. Character Format Selection

Control Bits		Character Format				
M	PEN-PTY	Start Bits	Data Bits	Parity	Stop Bits	Character Length
0	0X	1	8	None	1	10 Bits
1	0X	1	9	None	1	11 Bits
0	10	1	7	Even	1	10 Bits
0	11	1	7	Odd	1	10 Bits
1	10	1	8	Even	1	11 Bits
1	11	1	8	Odd	1	11 Bits

### 12.7.2 SCI Control Register 2

SCI control register 2 (SCC2):

- Enables these CPU interrupt requests:
  - Enables the SCTE bit to generate transmitter CPU interrupt requests
  - Enables the TC bit to generate transmitter CPU interrupt requests
  - Enables the SCRF bit to generate receiver CPU interrupt requests
  - Enables the IDLE bit to generate receiver CPU interrupt requests
- Enables the transmitter
- Enables the receiver
- Enables SCI wakeup
- Transmits SCI break characters

Figure 12-11. SCI Control Register 2 (SCC2)

#### SCTIE — SCI Transmit Interrupt Enable Bit

This read/write bit enables the SCTE bit to generate SCI transmitter CPU interrupt requests. Setting the SCTIE bit in SCC3 enables the SCTE bit to generate CPU interrupt requests. Reset clears the SCTIE bit.

- 1 = SCTE enabled to generate CPU interrupt
- 0 = SCTE not enabled to generate CPU interrupt

#### TCIE — Transmission Complete Interrupt Enable Bit

This read/write bit enables the TC bit to generate SCI transmitter CPU interrupt requests. Reset clears the TCIE bit.

- 1 = TC enabled to generate CPU interrupt requests
- 0 = TC not enabled to generate CPU interrupt requests

### SCRIE — SCI Receive Interrupt Enable Bit

This read/write bit enables the SCRF bit to generate SCI receiver CPU interrupt requests. Setting the SCRIE bit in SCC3 enables the SCRF bit to generate CPU interrupt requests. Reset clears the SCRIE bit.

- 1 = SCRF enabled to generate CPU interrupt
- 0 = SCRF not enabled to generate CPU interrupt

### ILIE — Idle Line Interrupt Enable Bit

This read/write bit enables the IDLE bit to generate SCI receiver CPU interrupt requests. Reset clears the ILIE bit.

- 1 = IDLE enabled to generate CPU interrupt requests
- 0 = IDLE not enabled to generate CPU interrupt requests

### TE — Transmitter Enable Bit

Setting this read/write bit begins the transmission by sending a preamble of 10 or 11 1s from the transmit shift register to the TxD pin. If software clears the TE bit, the transmitter completes any transmission in progress before the TxD returns to the idle condition (logic 1). Clearing and then setting TE during a transmission queues an idle character to be sent after the character currently being transmitted. Reset clears the TE bit.

- 1 = Transmitter enabled
- 0 = Transmitter disabled

#### **NOTE**

*Writing to the TE bit is not allowed when the enable SCI bit (ENSCI) is clear. ENSCI is in SCI control register 1.*

### RE — Receiver Enable Bit

Setting this read/write bit enables the receiver. Clearing the RE bit disables the receiver but does not affect receiver interrupt flag bits. Reset clears the RE bit.

- 1 = Receiver enabled
- 0 = Receiver disabled

#### **NOTE**

*Writing to the RE bit is not allowed when the enable SCI bit (ENSCI) is clear. ENSCI is in SCI control register 1.*

### RWU — Receiver Wakeup Bit

This read/write bit puts the receiver in a standby state during which receiver interrupts are disabled. The WAKE bit in SCC1 determines whether an idle input or an address mark brings the receiver out of the standby state and clears the RWU bit. Reset clears the RWU bit.

- 1 = Standby state
- 0 = Normal operation

### SBK — Send Break Bit

Setting and then clearing this read/write bit transmits a break character followed by a 1. The 1 after the break character guarantees recognition of a valid start bit. If SBK remains set, the transmitter continuously transmits break characters with no 1s between them. Reset clears the SBK bit.

- 1 = Transmit break characters
- 0 = No break characters being transmitted

#### **NOTE**

*Do not toggle the SBK bit immediately after setting the SCTE bit. Toggling SBK before the preamble begins causes the SCI to send a break character instead of a preamble.*

### 12.7.3 SCI Control Register 3

SCI control register 3 (SCC3):

- Stores the ninth SCI data bit received and the ninth SCI data bit to be transmitted.
- Enables these interrupts:
  - Receiver overrun interrupts
  - Noise error interrupts
  - Framing error interrupts
  - Parity error interrupts

**Figure 12-12. SCI Control Register 3 (SCC3)**

#### R8 — Received Bit 8

When the SCI is receiving 9-bit characters, R8 is the read-only ninth bit (bit 8) of the received character. R8 is received at the same time that the SCDR receives the other eight bits.

When the SCI is receiving 8-bit characters, R8 is a copy of the eighth bit (bit 7). Reset has no effect on the R8 bit.

#### T8 — Transmitted Bit 8

When the SCI is transmitting 9-bit characters, T8 is the read/write ninth bit (bit 8) of the transmitted character. T8 is loaded into the transmit shift register at the same time that the SCDR is loaded into the transmit shift register. Reset has no effect on the T8 bit.

#### ORIE — Receiver Overrun Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the receiver overrun bit, OR.

- 1 = SCI error CPU interrupt requests from OR bit enabled
- 0 = SCI error CPU interrupt requests from OR bit disabled

#### NEIE — Receiver Noise Error Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the noise error bit, NE. Reset clears NEIE.

- 1 = SCI error CPU interrupt requests from NE bit enabled
- 0 = SCI error CPU interrupt requests from NE bit disabled

#### FEIE — Receiver Framing Error Interrupt Enable Bit

This read/write bit enables SCI error CPU interrupt requests generated by the framing error bit, FE. Reset clears FEIE.

- 1 = SCI error CPU interrupt requests from FE bit enabled
- 0 = SCI error CPU interrupt requests from FE bit disabled

**PEIE — Receiver Parity Error Interrupt Enable Bit**

This read/write bit enables SCI receiver CPU interrupt requests generated by the parity error bit, PE. Reset clears PEIE.

- 1 = SCI error CPU interrupt requests from PE bit enabled
- 0 = SCI error CPU interrupt requests from PE bit disabled

**NOTE**

*Bits 5 and 4 are reserved for MCUs with a direct-memory access (DMA) module. Because the MC68HC908KX8 does not have a DMA module, these bits should not be set.*

**12.7.4 SCI Status Register 1**

SCI status register 1 (SCS1) contains flags to signal these conditions:

- Transfer of SCDR data to transmit shift register complete
- Transmission complete
- Transfer of receive shift register data to SCDR complete
- Receiver input idle
- Receiver overrun
- Noisy data
- Framing error
- Parity error

**Figure 12-13. SCI Status Register 1 (SCS1)**

**SCTE — SCI Transmitter Empty Bit**

This clearable, read-only bit is set when the SCDR transfers a character to the transmit shift register. SCTE can generate an SCI transmitter CPU interrupt request. When the SCTIE bit in SCC2 is set, SCTE generates an SCI transmitter CPU interrupt request. In normal operation, clear the SCTE bit by reading SCS1 with SCTE set and then writing to SCDR. Reset sets the SCTE bit.

- 1 = SCDR data transferred to transmit shift register
- 0 = SCDR data not transferred to transmit shift register

**TC — Transmission Complete Bit**

This read-only bit is set when the SCTE bit is set, and no data, preamble, or break character is being transmitted. TC generates an SCI transmitter CPU interrupt request if the TCIE bit in SCC2 is also set. TC is cleared automatically when data, preamble, or break is queued and ready to be sent. There may be up to 1.5 transmitter clocks of latency between queueing data, preamble, and break and the transmission actually starting. Reset sets the TC bit.

- 1 = No transmission in progress
- 0 = Transmission in progress

**SCRF — SCI Receiver Full Bit**

This clearable, read-only bit is set when the data in the receive shift register transfers to the SCI data register. SCRF can generate an SCI receiver CPU interrupt request. When the SCRIE bit in SCC2 is set the SCRF generates a CPU interrupt request. In normal operation, clear the SCRF bit by reading SCS1 with SCRF set and then reading the SCDR. Reset clears SCRF.

- 1 = Received data available in SCDR
- 0 = Data not available in SCDR

**IDLE — Receiver Idle Bit**

This clearable, read-only bit is set when 10 or 11 consecutive 1s appear on the receiver input. IDLE generates an SCI error CPU interrupt request if the ILIE bit in SCC2 is also set. Clear the IDLE bit by reading SCS1 with IDLE set and then reading the SCDR. After the receiver is enabled, it must receive a valid character that sets the SCRF bit before an idle condition can set the IDLE bit. Also, after the IDLE bit has been cleared, a valid character must again set the SCRF bit before an idle condition can set the IDLE bit. Reset clears the IDLE bit.

- 1 = Receiver input idle
- 0 = Receiver input active (or idle since the IDLE bit was cleared)

**OR — Receiver Overrun Bit**

This clearable, read-only bit is set when software fails to read the SCDR before the receive shift register receives the next character. The OR bit generates an SCI error CPU interrupt request if the ORIE bit in SCC3 is also set. The data in the shift register is lost, but the data already in the SCDR is not affected. Clear the OR bit by reading SCS1 with OR set and then reading the SCDR. Reset clears the OR bit.

- 1 = Receive shift register full and SCRF = 1
- 0 = No receiver overrun

Software latency may allow an overrun to occur between reads of SCS1 and SCDR in the flag-clearing sequence. [Figure 12-14](#) shows the normal flag-clearing sequence and an example of an overrun caused by a delayed flag-clearing sequence. The delayed read of SCDR does not clear the OR bit because OR was not set when SCS1 was read. Byte 2 caused the overrun and is lost. The next flag-clearing sequence reads byte 3 in the SCDR instead of byte 2.

In applications that are subject to software latency or in which it is important to know which byte is lost due to an overrun, the flag-clearing routine can check the OR bit in a second read of SCS1 after reading the data register.

**NF — Receiver Noise Flag Bit**

This clearable, read-only bit is set when the SCI detects noise on the RxD pin. NF generates an NF CPU interrupt request if the NEIE bit in SCC3 is also set. Clear the NF bit by reading SCS1 and then reading the SCDR. Reset clears the NF bit.

- 1 = Noise detected
- 0 = No noise detected

**FE — Receiver Framing Error Bit**

This clearable, read-only bit is set when a 0 is accepted as the stop bit. FE generates an SCI error CPU interrupt request if the FEIE bit in SCC3 also is set. Clear the FE bit by reading SCS1 with FE set and then reading the SCDR. Reset clears the FE bit.

- 1 = Framing error detected
- 0 = No framing error detected

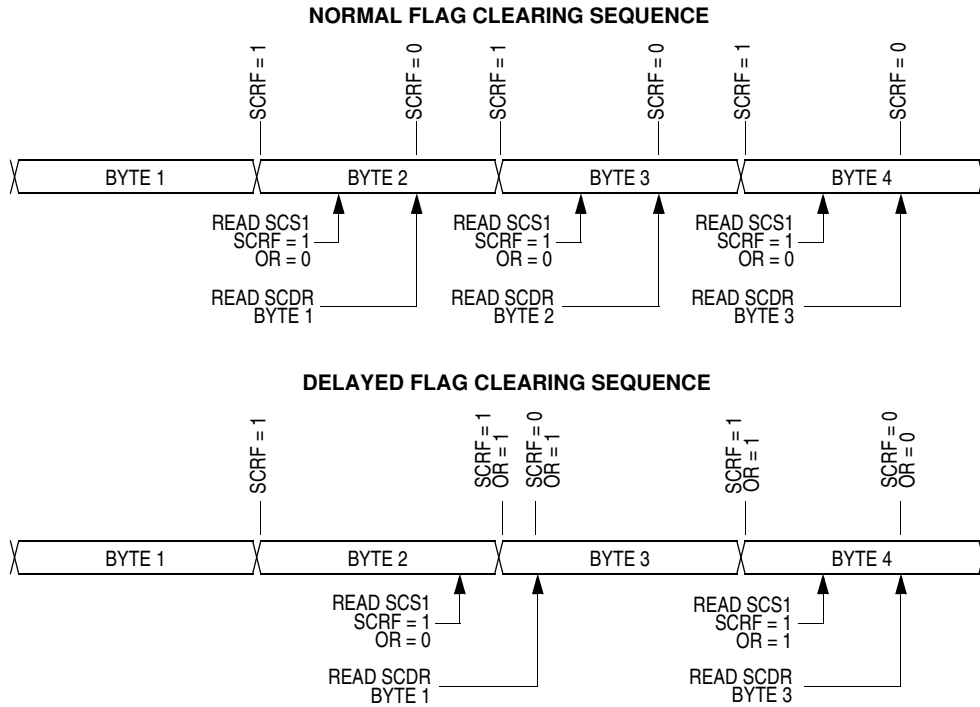

Figure 12-14. Flag Clearing Sequence

**PE — Receiver Parity Error Bit**

This clearable, read-only bit is set when the SCI detects a parity error in incoming data. PE generates a PE CPU interrupt request if the PEIE bit in SCC3 is also set. Clear the PE bit by reading SCS1 with PE set and then reading the SCDR. Reset clears the PE bit.

- 1 = Parity error detected
- 0 = No parity error detected

**12.7.5 SCI Status Register 2**

SCI status register 2 (SCS2) contains flags to signal these conditions:

- Break character detected
- Incoming data

Address: \$0017

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	0	0	0	BKF	RPF
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented

Figure 12-15. SCI Status Register 2 (SCS2)

**BKF — Break Flag Bit**

This clearable, read-only bit is set when the SCI detects a break character on the RxD pin. In SCS1, the FE and SCRF bits are also set. In 9-bit character transmissions, the R8 bit in SCC3 is cleared. BKF does not generate a CPU interrupt request. Clear BKF by reading SCS2 with BKF set and then reading

the SCDR. Once cleared, BKF can become set again only after 1s again appear on the RxD pin followed by another break character. Reset clears the BKF bit.

- 1 = Break character detected
- 0 = No break character detected

### RPF — Reception-in-Progress Flag Bit

This read-only bit is set when the receiver detects a 0 during the RT1 time period of the start bit search. RPF does not generate an interrupt request. RPF is reset after the receiver detects false start bits (usually from noise or a baud rate mismatch), or when the receiver detects an idle character. Polling RPF before disabling the SCI module or entering stop mode can show whether a reception is in progress.

- 1 = Reception in progress
- 0 = No reception in progress

## 12.7.6 SCI Data Register

The SCI data register (SCDR) is the buffer between the internal data bus and the receive and transmit shift registers. Reset has no effect on data in the SCI data register.

Address: \$0018

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	R7	R6	R5	R4	R3	R2	R1	R0
Write:	T7	T6	T5	T4	T3	T2	T1	T0
Reset:	Unaffected by reset							

**Figure 12-16. SCI Data Register (SCDR)**

### R7/T7–R0/T0 — Receive/Transmit Data Bits

Reading address \$0018 accesses the read-only received data bits, R7–R0. Writing to address \$0018 writes the data to be transmitted, T7–T0. Reset has no effect on the SCI data register.

#### NOTE

*Do not use read-modify-write instructions on the SCI data register.*

## 12.7.7 SCI Baud Rate Register

The baud rate register (SCBR) selects the baud rate for both the receiver and the transmitter.

Address: \$0019

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	SCP1	SCP0	R	SCR2	SCR1	SCR0
Write:								
Reset:	0	0	0	0	0	0	0	0

= Unimplemented     
 R = Reserved

**Figure 12-17. SCI Baud Rate Register (SCBR)**

**SCP1 and SCP0 — SCI Baud Rate Prescaler Bits**

These read/write bits select the baud rate prescaler divisor as shown in [Table 12-6](#). Reset clears SCP1 and SCP0.

**Table 12-6. SCI Baud Rate Prescaling**

SCP[1:0]	Prescaler Divisor (PD)
00	1
01	3
10	4
11	13

**SCR2–SCR0 — SCI Baud Rate Select Bits**

These read/write bits select the SCI baud rate divisor as shown in [Table 12-7](#). Reset clears SCR2–SCR0.

**Table 12-7. SCI Baud Rate Selection**

SCR[2:1:0]	Baud Rate Divisor (BD)
000	1
001	2
010	4
011	8
100	16
101	32
110	64
111	128

Use this formula to calculate the SCI baud rate:

$$\text{Baud rate} = \frac{f_{\text{BAUDCLK}}}{64 \times \text{PD} \times \text{BD}}$$

where:

$f_{\text{BAUDCLK}}$  = baud clock frequency

PD = prescaler divisor

BD = baud rate divisor

[Table 12-8](#) shows the SCI baud rates that can be generated with a 4.9152-MHz CGMXCLK frequency.

Table 12-8. SCI Baud Rate Selection Examples

SCP[1:0]	Prescaler Divisor (PD)	SCR[2:1:0]	Baud Rate Divisor (BD)	Baud Rate (f <sub>BAUDCLK</sub> = 4.9152 MHz)
00	1	000	1	76,800
00	1	001	2	38,400
00	1	010	4	19,200
00	1	011	8	9600
00	1	100	16	4800
00	1	101	32	2400
00	1	110	64	1200
00	1	111	128	600
01	3	000	1	25,600
01	3	001	2	12,800
01	3	010	4	6400
01	3	011	8	3200
01	3	100	16	1600
01	3	101	32	800
01	3	110	64	400
01	3	111	128	200
10	4	000	1	19,200
10	4	001	2	9600
10	4	010	4	4800
10	4	011	8	2400
10	4	100	16	1200
10	4	101	32	600
10	4	110	64	300
10	4	111	128	150
11	13	000	1	5908
11	13	001	2	2954
11	13	010	4	1477
11	13	011	8	739
11	13	100	16	369

11	13	110	64	92
11	13	111	128	46

# Chapter 13

## System Integration Module (SIM)

### 13.1 Introduction

This section describes the system integration module (SIM), which supports up to 24 external and/or internal interrupts. The SIM is a system state controller that coordinates the central processor unit (CPU) and exception timing. Together with the CPU, the SIM controls all microcontroller unit (MCU) activities.

Figure 13-1 is a summary of the SIM input/output (I/O) registers. A block diagram of the SIM is shown in Figure 13-2.

The SIM is responsible for:

- Bus clock generation and control for CPU and peripherals:
  - Stop/wait/reset entry and recovery
  - Internal clock control
- Master reset control, including power-on reset (POR) and computer operating properly (COP) timeout
- Interrupt control:
  - Acknowledge timing
  - Arbitration control timing
  - Vector address generation
- CPU enable/disable timing
- Modular architecture expandable to 128 interrupt sources

Addr.	Register Name		Bit 7	6	5	4	3	2	1	Bit 0

**Figure 13-1. SIM I/O Register Summary**

## System Integration Module (SIM)

**Figure 13-2. SIM Block Diagram**

Table 13-1 shows the internal signal names used in this section.

**Table 13-1. Signal Name Conventions**

Signal Name	Description
CGMXCLK	Selected clock source from internal clock generator module (ICG)
CGMOUT	Clock output from ICG module (bus clock = CGMOUT divided by two)
IAB	Internal address bus
IDB	Internal data bus
PORRST	Signal from the power-on reset (POR) module to the SIM
IRST	Internal reset signal
R/ $\bar{W}$	Read/write signal

## 13.2 SIM Bus Clock Control and Generation

The bus clock generator provides system clock signals for the CPU and peripherals on the MCU. The system clocks are generated from an incoming clock, CGMOUT, as shown in [Figure 13-3](#). This clock originates from either an external oscillator or from the internal clock generator.

**Figure 13-3. System Clock Signals**

### 13.2.1 Bus Timing

In user mode, the internal bus frequency is the internal clock generator output (CGMXCLK) divided by four.

### 13.2.2 Clock Startup from POR or LVI Reset

When the power-on reset (POR) module or the low-voltage inhibit (LVI) module generates a reset, the clocks to the CPU and peripherals are inactive and held in an inactive phase until after 4096 CGMXCLK cycles. The MCU is held in reset by the SIM during this entire period. The bus clocks start upon completion of the timeout.

### 13.2.3 Clocks in Stop Mode and Wait Mode

Upon exit from stop mode by an interrupt or reset, the SIM allows CGMXCLK to clock the SIM counter. The CPU and peripheral clocks do not become active until after the stop delay timeout. Stop mode recovery timing is discussed in detail in [13.6.2 Stop Mode](#).

In wait mode, the CPU clocks are inactive. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

## 13.3 Reset and System Initialization

The MCU has these internal reset sources:

- Power-on reset (POR) module
- Computer operating properly (COP) module
- Low-voltage inhibit (LVI) module
- Illegal opcode
- Illegal address
- Forced monitor mode entry reset (MENRST) module

All of these resets produce the vector \$FFFE–\$FFFF (\$FEFE–\$FEFF in monitor mode) and assert the internal reset signal (IRST). IRST causes all registers to be returned to their default values and all modules to be returned to their reset states.

These internal resets clear the SIM counter and set a corresponding bit in the SIM reset status register (SRSR). See [13.4 SIM Counter](#) and [13.7.1 SIM Reset Status Register](#).

### 13.3.1 Active Resets from Internal Sources

An internal reset can be caused by an illegal address, illegal opcode, COP timeout, LVI, POR, or MENRST as shown in [Figure 13-4](#).

#### NOTE

*For LVI or POR resets, the SIM cycles through 4096 CGMXCLK cycles during which the SIM asserts IRST. The internal reset signal then follows with the 64-cycle phase as shown in [Figure 13-5](#).*

The COP reset is asynchronous to the bus clock.

**Figure 13-4. Sources of Internal Reset**

**Figure 13-5. Internal Reset Timing**

### 13.3.1.1 Power-On Reset

When power is first applied to the MCU, the power-on reset (POR) module generates a pulse to indicate that power-on has occurred. The MCU is held in reset while the SIM counter counts out 4096 CGMXCLK cycles. Another 64 CGMXCLK cycles later, the CPU and memories are released from reset to allow the reset vector sequence to occur.

At power-on, these events occur:

- A POR pulse is generated.
- The internal reset signal is asserted.
- The SIM enables CGMOUT.
- Internal clocks to the CPU and modules are held inactive for 4096 CGMXCLK cycles to allow stabilization of the internal clock generator.
- The POR bit of the SIM reset status register (SRSR) is set and all other bits in the register are cleared.

Figure 13-6. POR Recovery

### 13.3.1.2 Computer Operating Properly (COP) Reset

An input to the SIM is reserved for the COP reset signal. The overflow of the COP counter causes an internal reset and sets the COP bit in the reset status register (SRSR).

To prevent a COP module timeout, write any value to location \$FFFF. Writing to location \$FFFF clears the COP counter and stages 12–5 of the SIM counter. The SIM counter output, which occurs at least every  $2^{12}$ – $2^4$  CGMXCLK cycles, drives the COP counter. The COP should be serviced as soon as possible out of reset to guarantee the maximum amount of time before the first timeout.

The COP module is disabled if the  $\overline{\text{IRQ1}}$  pin is held at  $V_{\text{TST}}$  while the MCU is in monitor mode. The COP module can be disabled only through combinational logic conditioned with the high-voltage signal on the  $\overline{\text{IRQ1}}$  pin. This prevents the COP from becoming disabled as a result of external noise.

### 13.3.1.3 Illegal Opcode Reset

The SIM decodes signals from the CPU to detect illegal instructions. An illegal instruction sets the ILOP bit in the SIM reset status register (SRSR) and causes a reset.

If the stop enable bit, STOP, in the configuration register (CONFIG1) is 0, the SIM treats the STOP instruction as an illegal opcode and causes an illegal opcode reset.

### 13.3.1.4 Illegal Address Reset

An opcode fetch from an unmapped address generates an illegal address reset. The SIM verifies that the CPU is fetching an opcode prior to asserting the ILAD bit in the SIM reset status register (SRSR) and resetting the MCU. A data fetch from an unmapped address does not generate a reset.

### 13.3.1.5 Forced Monitor Mode Entry Reset (MENRST)

The MENRST module is monitoring the reset vector fetches and will assert an internal reset if it detects that the reset vectors are erased (\$FF). When the MCU comes out of reset, it is forced into monitor mode. See [16.3 Monitor ROM \(MON\)](#).

### 13.3.1.6 Low-Voltage Inhibit (LVI) Reset

The low-voltage inhibit module (LVI) asserts its output to the SIM when the  $V_{DD}$  voltage falls to the  $V_{TRIPF}$  voltage. The LVI bit in the SIM reset status register (SRSR) is set and a chip reset is asserted if the LVIPWRD and LVIRSTD bits in the CONFIG register are at 0. The MCU is held in reset until  $V_{DD}$  rises above  $V_{TRIPR}$ . The MCU remains in reset until the SIM counts 4096 CGMXCLK to begin a reset recovery. Another 64 CGMXCLK cycles later, the CPU is released from reset to allow the reset vector sequence to occur. See [Chapter 10 Low-Voltage Inhibit \(LVI\)](#).

## 13.4 SIM Counter

The SIM counter is used by the power-on reset module (POR) and in stop mode recovery to allow the oscillator time to stabilize before enabling the internal bus (IBUS) clocks. The SIM counter also serves as a prescaler for the computer operating properly module (COP). The SIM counter overflow supplies the clock for the COP module. The SIM counter is 12 bits long and is clocked by the falling edge of CGMXCLK.

### 13.4.1 SIM Counter During Power-On Reset

The power-on reset module (POR) detects power applied to the MCU. At power-on, the POR circuit asserts the signal PORRST. Once the SIM is initialized, it enables the internal clock generator to drive the bus clock state machine.

### 13.4.2 SIM Counter During Stop Mode Recovery

The SIM counter also is used for stop mode recovery. The STOP instruction clears the SIM counter. After an interrupt or reset, the SIM senses the state of the short stop recovery bit, SSREC, in the configuration register. If the SSREC bit is a 1, then the stop recovery is reduced from the normal delay of 4096 CGMXCLK cycles down to 32 CGMXCLK cycles.

### 13.4.3 SIM Counter and Reset States

The SIM counter is free-running after all reset states. See [13.3.1 Active Resets from Internal Sources](#) for counter control and internal reset recovery sequences.

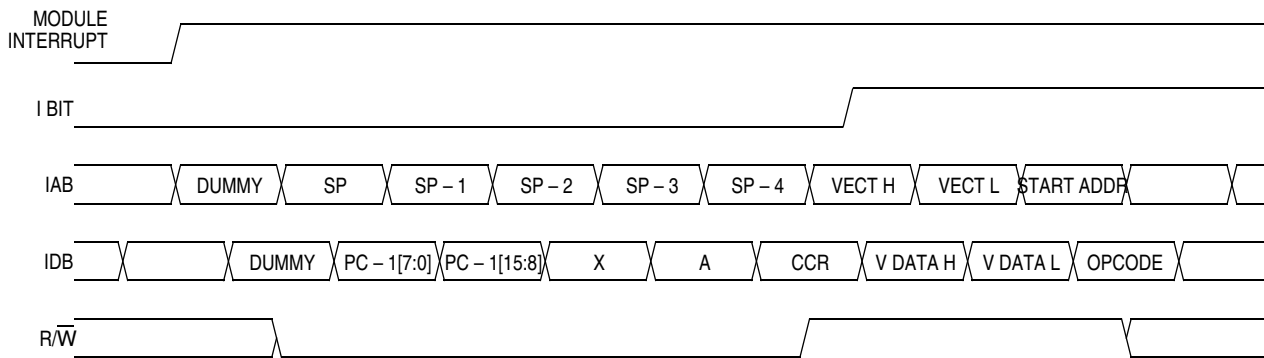

## 13.5 Program Exception Control

Normal, sequential program execution can be changed in two ways:

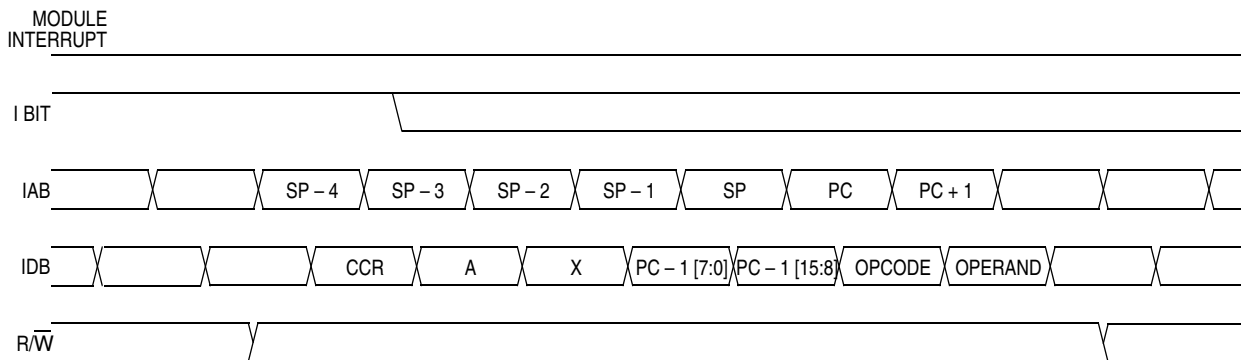

1. Interrupts
  - a. Maskable hardware CPU interrupts
  - b. Non-maskable software interrupt instruction (SWI)
2. Reset

### 13.5.1 Interrupts

At the beginning of an interrupt, the CPU saves the CPU register contents on the stack and sets the interrupt mask (I bit) to prevent additional interrupts. At the end of an interrupt, the return-from-interrupt (RTI) instruction recovers the CPU register contents from the stack so that normal processing can resume. [Figure 13-7](#) shows interrupt entry timing. [Figure 13-8](#) shows interrupt recovery timing.

**Figure 13-7. Interrupt Entry**

**Figure 13-8. Interrupt Recovery**

Interrupts are latched, and arbitration is performed in the SIM at the start of interrupt processing. The arbitration result is a constant that the CPU uses to determine which vector to fetch. As shown in [Figure 13-9](#), once an interrupt is latched by the SIM, no other interrupt can take precedence, regardless of priority, until the latched interrupt is serviced or the I bit is cleared.

**Figure 13-9. Interrupt Processing**

**13.5.1.1 Hardware Interrupts**

A hardware interrupt does not stop the current instruction. Processing of a hardware interrupt begins after completion of the current instruction. When the current instruction is complete, the SIM checks all pending hardware interrupts. If interrupts are not masked (I bit clear in the condition code register), and if the corresponding interrupt enable bit is set, the SIM proceeds with interrupt processing; otherwise, the next instruction is fetched and executed.

If more than one interrupt is pending at the end of an instruction execution, the highest priority interrupt is serviced first. [Figure 13-10](#) demonstrates what happens when two interrupts are pending. If an interrupt

is pending upon exit from the original interrupt service routine, the pending interrupt is serviced before the load-accumulator- from-memory (LDA) instruction is executed.

The LDA opcode is prefetched by both the INT1 and INT2 RTI instructions. However, in the case of the INT1 RTI prefetch, this is a redundant operation.

#### NOTE

*To maintain compatibility with the M68HC05, M6805, and M146805 Families the H register is not pushed on the stack during interrupt entry. If the interrupt service routine modifies the H register or uses the indexed addressing mode, software should save the H register and then restore it prior to exiting the routine.*

Figure 13-10. Interrupt Recognition Example

#### 13.5.1.2 SWI Instruction

The SWI instruction is a non-maskable instruction that causes an interrupt regardless of the state of the interrupt mask (I bit) in the condition code register.

#### NOTE

*A software interrupt pushes PC onto the stack. A software interrupt does **not** push PC - 1, as a hardware interrupt does.*

#### 13.5.2 Reset

All reset sources always have higher priority than interrupts and cannot be arbitrated.

### 13.6 Low-Power Modes

Executing the WAIT or STOP instruction puts the MCU in a low power- consumption mode for standby situations. The SIM holds the CPU in a non-clocked state. Both STOP and WAIT clear the interrupt mask (I) in the condition code register, allowing interrupts to occur. Low-power modes are exited via an interrupt or reset.

### 13.6.1 Wait Mode

In wait mode, the CPU clocks are inactive while one set of peripheral clocks continues to run. [Figure 13-11](#) shows the timing for wait mode entry.

Note: Previous data can be operand data or the WAIT opcode, depending on the last instruction.

**Figure 13-11. Wait Mode Entry Timing**

A module that is active during wait mode can wake up the CPU with an interrupt if the interrupt is enabled. Stacking for the interrupt begins one cycle after the WAIT instruction during which the interrupt occurred. Refer to the wait mode subsection of each module to see if the module is active or inactive in wait mode. Some modules can be programmed to be active in wait mode.

Wait mode can also be exited by a reset. If the COP disable bit, COPD, in the configuration register is a 0, then the computer operating properly module (COP) is enabled and remains active in wait mode.

[Figure 13-12](#) and [Figure 13-13](#) show the timing for WAIT recovery.

Note: EXITSTOPWAIT = CPU interrupt

**Figure 13-12. Wait Recovery from Interrupt**

**Figure 13-13. Wait Recovery from Internal Reset**

### 13.6.2 Stop Mode

In stop mode, the SIM counter is held in reset and the CPU and peripheral clocks are held inactive. If the OSCENINSTOP bit in the configuration register is not enabled, the SIM also disables the internal clock generator module outputs (CGMOUT and CGMXCLK).

The CPU and peripheral clocks do not become active until after the stop delay timeout. Stop mode is exited via an interrupt request from a module that is still active in stop mode or from a system reset.

An interrupt request from a module that is still active in stop mode can cause an exit from stop mode. Stop recovery time is selectable using the SSREC bit in the configuration register. If SSREC is set, stop recovery is reduced from the normal delay of 4096 CGMXCLK cycles down to 32. Stacking for interrupts begins after the selected stop recovery time has elapsed.

When stop mode is exited due to a reset condition, the SIM forces a long stop recovery time of 4096 CGMXCLK cycles.

**NOTE**

*Short stop recovery is ideal for applications using canned oscillators that do not require long startup times for stop mode. External crystal applications should use the full stop recovery time by clearing the SSREC bit.*

The SIM counter is held in reset from the execution of the STOP instruction until the beginning of stop recovery. It is then used to time the recovery period. Figure 13-14 shows stop mode entry timing.

Note: Previous data can be operand data or the STOP opcode, depending on the last instruction.

**Figure 13-14. Stop Mode Entry Timing**

**Figure 13-15. Stop Mode Recovery from Interrupt**

## 13.7 SIM Registers

The SIM has four memory mapped registers described here.

1. SIM reset status register (SRSR)
2. Interrupt status register 1 (INT1)
3. Interrupt status register 2 (INT2)
4. Interrupt status register 2 (INT3)

### 13.7.1 SIM Reset Status Register

This register contains five bits that show the source of the last reset. The status register will clear automatically after reading it. A power-on reset sets the POR bit and clears all other bits in the register.

Address: \$FE01

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	POR	0	COP	ILOP	ILAD	MENRST	LVI	0
Write:								
POR:	1	0	0	0	0	0	0	0

 = Unimplemented

**Figure 13-16. SIM Reset Status Register (SRSR)**

#### **POR — Power-On Reset Bit**

- 1 = Last reset caused by POR circuit
- 0 = Read of SRSR

#### **COP — Computer Operating Properly Reset Bit**

- 1 = Last reset caused by COP counter
- 0 = POR or read of SRSR

#### **ILOP — Illegal Opcode Reset Bit**

- 1 = Last reset caused by an illegal opcode
- 0 = POR or read of SRSR

#### **ILAD — Illegal Address Reset Bit (opcode fetches only)**

- 1 = Last reset caused by an opcode fetch from an illegal address
- 0 = POR or read of SRSR

#### **MENRST — Forced Monitor Mode Entry Reset Bit**

- 1 = Last reset was caused by the MENRST circuit
- 0 = POR or read of SRSR

#### **LVI — Low-Voltage Inhibit Reset Bit**

- 1 = Last reset was caused by the LVI circuit
- 0 = POR or read of SRSR

## 13.7.2 Interrupt Status Registers

The flags in the interrupt status registers identify maskable interrupt sources. The interrupt sources and the interrupt status register flags that they set are summarized in [Table 13-2](#). The interrupt status registers can be useful for debugging.

**Table 13-2. Interrupt Sources**

Source	Flag	Mask <sup>(1)</sup>	INT Register Flag	Priority <sup>(2)</sup>	Vector Address
SWI instruction	—	—	—	0	\$FFFC–\$FFFD
IRQ1 pin	IRQF1	IMASK1	IF1	1	\$FFFA–\$FFFB
ICG clock monitor	CMF	CMIE	IF2	2	\$FFF8–\$FFF9
TIM channel 0	CH0F	CH0IE	IF3	3	\$FFF6–\$FFF7
TIM channel 1	CH1F	CH1IE	IF4	4	\$FFF4–\$FFF5
TIM overflow	TOF	TOIE	IF5	5	\$FFF2–\$FFF3
SCI receiver overrun error	OR	ORIE	IF11	6	\$FFE6–\$FFE7
SCI receiver noise error	NF	NEIE			
SCI receiver framing error	FE	FEIE			
SCI receiver parity error	PE	PEIE			
SCI receiver full	SCRF	SCRIE	IF12	7	\$FFE4–\$FFE5
SCI receiver idle	IDLE	ILIE			
SCI transmitter empty	SCTE	SCTIE	IF13	8	\$FFE2–\$FFE3
SCI transmission complete	TC	TCIE			
Keyboard pins	KEYF	IMASKK	IF14	9	\$FFE0–\$FFE1
ADC conversion complete	—	AIEN	IF15	10	\$FFDE–\$FFDF
Timebase module	TBIE	TBF	IF16	11	\$FFDC–\$FFDD

1. The I bit in the condition code register is a global mask for all interrupt sources except the SWI instruction.

2. 0 = highest priority

### 13.7.2.1 Interrupt Status Register 1

Address: \$FE04

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IF6	IF5	IF4	IF3	IF2	IF1	0	0
Write:	R	R	R	R	R	R	R	R
Reset:	0	0	0	0	0	0	0	0

R = Reserved

**Figure 13-17. Interrupt Status Register 1 (INT1)**

#### IF5–IF1 — Interrupt Flags 5, 4, 3, 2, and 1

These flags indicate the presence of interrupt requests from the sources shown in [Table 13-2](#).

1 = Interrupt request present

0 = No interrupt request present

### IF6 — Interrupt Flag 6

Since the MC68HC908KX8 parts do not use this interrupt flag, this bit will always read 0.

Bit 0 and Bit 1 — Always read 0

#### 13.7.2.2 Interrupt Status Register 2

Address: \$FE05

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IF14	IF13	IF12	IF11	IF10	IF9	IF8	IF7
Write:	R	R	R	R	R	R	R	R
Reset:	0	0	0	0	0	0	0	0

R = Reserved

**Figure 13-18. Interrupt Status Register 2 (INT2)**

### IF14–IF11 — Interrupt Flags 14–11

These flags indicate the presence of interrupt requests from the sources shown in [Table 13-2](#).

1 = Interrupt request present

0 = No interrupt request present

### IF10–IF7 — Interrupt Flags 10–7

Since the MC68HC908KX8 parts do not use these interrupt flags, these bits will always read 0.

#### 13.7.2.3 Interrupt Status Register 3

Address: \$FE06

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	IF22	IF21	IF20	IF19	IF18	IF17	IF16	IF15
Write:	R	R	R	R	R	R	R	R
Reset:	0	0	0	0	0	0	0	0

R = Reserved

**Figure 13-19. Interrupt Status Register 3 (INT3)**

### IF22–IF17 — Interrupt Flags 22–17

Since the MC68HC908KX8 parts do not use these interrupt flags, these bits will always read 0.

### IF16–IF15 — Interrupt Flags 16–15

These flags indicate the presence of interrupt requests from the sources shown in [Table 13-2](#).

1 = Interrupt request present

0 = No interrupt request present

# Chapter 14

## Timebase Module (TBM)

### 14.1 Introduction

This section describes the timebase module (TBM). The TBM will generate periodic interrupts at user selectable rates using a counter clocked by either the internal or external clock sources. This TBM version uses 15 divider stages, eight of which are user selectable.

### 14.2 Features

Features of the TBM module include:

- Software configurable periodic interrupts with divide by 8, 16, 32, 64, 128, 2048, 8192, and 32,768 taps of the selected clock source
- Configurable for operation during stop mode to allow periodic wake up from stop

### 14.3 Functional Description

This module can generate a periodic interrupt by dividing the clock source supplied from the internal clock generator module, TBMCLK. Note that this clock source is the external clock ECLK when the ECGON bit in the ICG control register (ICGCR) is set. Otherwise, TBMCLK is driven at the internally generated clock frequency (ICLK). In other words, if the external clock is enabled it will be used as the TBMCLK, even if the MCU bus clock is based on the internal clock.

The counter is initialized to all 0s when TBON bit is cleared. The counter, shown in [Figure 14-1](#), starts counting when the TBON bit is set. When the counter overflows at the tap selected by TBR2–TBR0, the TBIF bit gets set. If the TBIE bit is set, an interrupt request is sent to the CPU. The TBIF flag is cleared by writing a 1 to the TACK bit. The first time the TBIF flag is set after enabling the timebase module, the interrupt is generated at approximately half of the overflow period. Subsequent events occur at the exact period.

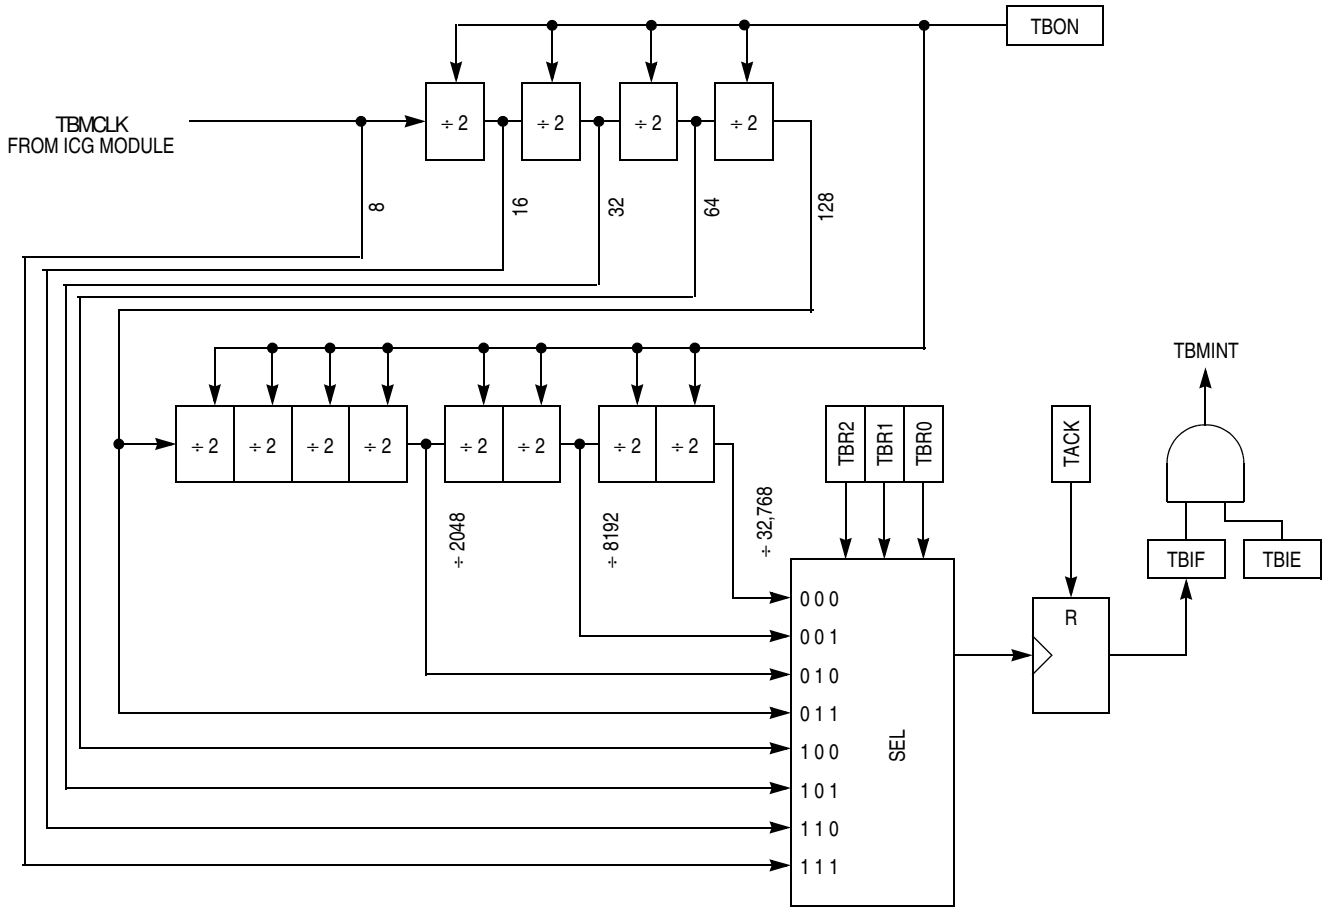

The timebase module may remain active after execution of the STOP instruction if the internal clock generator has been enabled to operate during stop mode through the OSCENINSTOP bit in the configuration register. The timebase module can be used in this mode to generate a periodic wakeup from stop mode.

### 14.4 Interrupts

The timebase module can periodically interrupt the CPU with a rate defined by the selected TBMCLK and the select bits TBR2–TBR0. When the timebase counter chain rolls over, the TBIF flag is set. If the TBIE bit is set, enabling the timebase interrupt, the counter chain overflow will generate a CPU interrupt request.

Interrupts must be acknowledged by writing a 1 to the TACK bit.

**Timebase Module (TBM)**

**Figure 14-1. Timebase Block Diagram**

## 14.5 TBM Interrupt Rate

The interrupt rate is determined by the equation:

$$t_{\text{TBM RATE}} = \frac{1}{f_{\text{TBM RATE}}} = \frac{\text{Divider}}{f_{\text{TBM CLK}}}$$

where:

$f_{\text{TBM CLK}}$  = Frequency supplied from the internal clock generator (ICG) module

Divider = Divider value as determined by TBR2–TBR0 settings. See [Table 14-1](#).

As an example, a clock source of 4.9152 MHz and the TBR2–TBR0 set to {011}, the divider tap is 128 and the interrupt rate calculates to  $128/4.9152 \times 10^6 = 26 \mu\text{s}$ .

**Table 14-1. Timebase Divider Selection**

TBR2	TBR1	TBR0	Divider Tap
0	0	0	32768
0	0	1	8192
0	1	0	2048
0	1	1	128
1	0	0	64
1	0	1	32
1	1	0	16
1	1	1	8

### NOTE

*Do not change TBR2–TBR0 bits while the timebase is enabled (TBON = 1).*

## 14.6 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

### 14.6.1 Wait Mode

The timebase module remains active after execution of the WAIT instruction. In wait mode the timebase register is not accessible by the CPU.

If the timebase functions are not required during wait mode, reduce the power consumption by stopping the timebase before executing the WAIT instruction.

### 14.6.2 Stop Mode

The timebase module may remain active after execution of the STOP instruction if the internal clock generator has been enabled to operate during stop mode through the OSCENINSTOP bit in the configuration register. The timebase module can be used in this mode to generate a periodic wake up from stop mode.

If the internal clock generator has not been enabled to operate in stop mode, the timebase module will not be active during stop mode. In stop mode, the timebase register is not accessible by the CPU.

If the timebase functions are not required during stop mode, reduce power consumption by disabling the timebase module before executing the STOP instruction.

## 14.7 Timebase Control Register

The timebase has one register, the timebase control register (TBCR), which is used to enable the timebase interrupts and set the rate.

**Figure 14-2. Timebase Control Register (TBCR)**

### TBIF — Timebase Interrupt Flag

This read-only flag bit is set when the timebase counter has rolled over.

1 = Timebase interrupt pending

0 = Timebase interrupt not pending

### TBR2–TBR0 — Timebase Divider Selection Bits

These read/write bits select the tap in the counter to be used for timebase interrupts as shown in [Table 14-1](#).

#### **NOTE**

*Do not change TBR2–TBR0 bits while the timebase is enabled (TBON = 1).*

### TACK— Timebase ACKnowledge Bit

The TACK bit is a write-only bit and always reads as 0. Writing a 1 to this bit clears TBIF, the timebase interrupt flag bit. Writing a 0 to this bit has no effect.

1 = Clear timebase interrupt flag

0 = No effect

### TBIE — Timebase Interrupt Enabled Bit

This read/write bit enables the timebase interrupt when the TBIF bit becomes set. Reset clears the TBIE bit.

1 = Timebase interrupt is enabled.

0 = Timebase interrupt is disabled.

### TBON — Timebase Enabled Bit

This read/write bit enables the timebase. Timebase may be turned off to reduce power consumption when its function is not necessary. The counter can be initialized by clearing and then setting this bit. Reset clears the TBON bit.

1 = Timebase is enabled.

0 = Timebase is disabled and the counter initialized to 0s.

# Chapter 15

## Timer Interface Module (TIM)

### 15.1 Introduction

This section describes the timer interface module (TIM). The TIM is a 2-channel timer that provides a timing reference with input capture, output compare, and pulse-width modulation functions. [Figure 15-2](#) is a block diagram of the TIM.

### 15.2 Features

Features include:

- Two input capture/output compare channels:
  - Rising-edge, falling-edge, or any-edge input capture trigger
  - Set, clear, or toggle output compare action
- Buffered and unbuffered pulse-width modulation (PWM) signal generation
- Programmable TIM clock input — 7-frequency internal bus clock prescaler selection
- Free-running or modulo up-counter operation
- Toggle either channel pin on overflow
- TIM counter stop and reset bits

### 15.3 Pin Name Conventions

The TIM shares two input/output (I/O) pins with two port A I/O pins. The full names of the TIM I/O pins are listed in [Table 15-1](#). The generic pin names appear in the text that follows.

**Table 15-1. Pin Name Conventions**

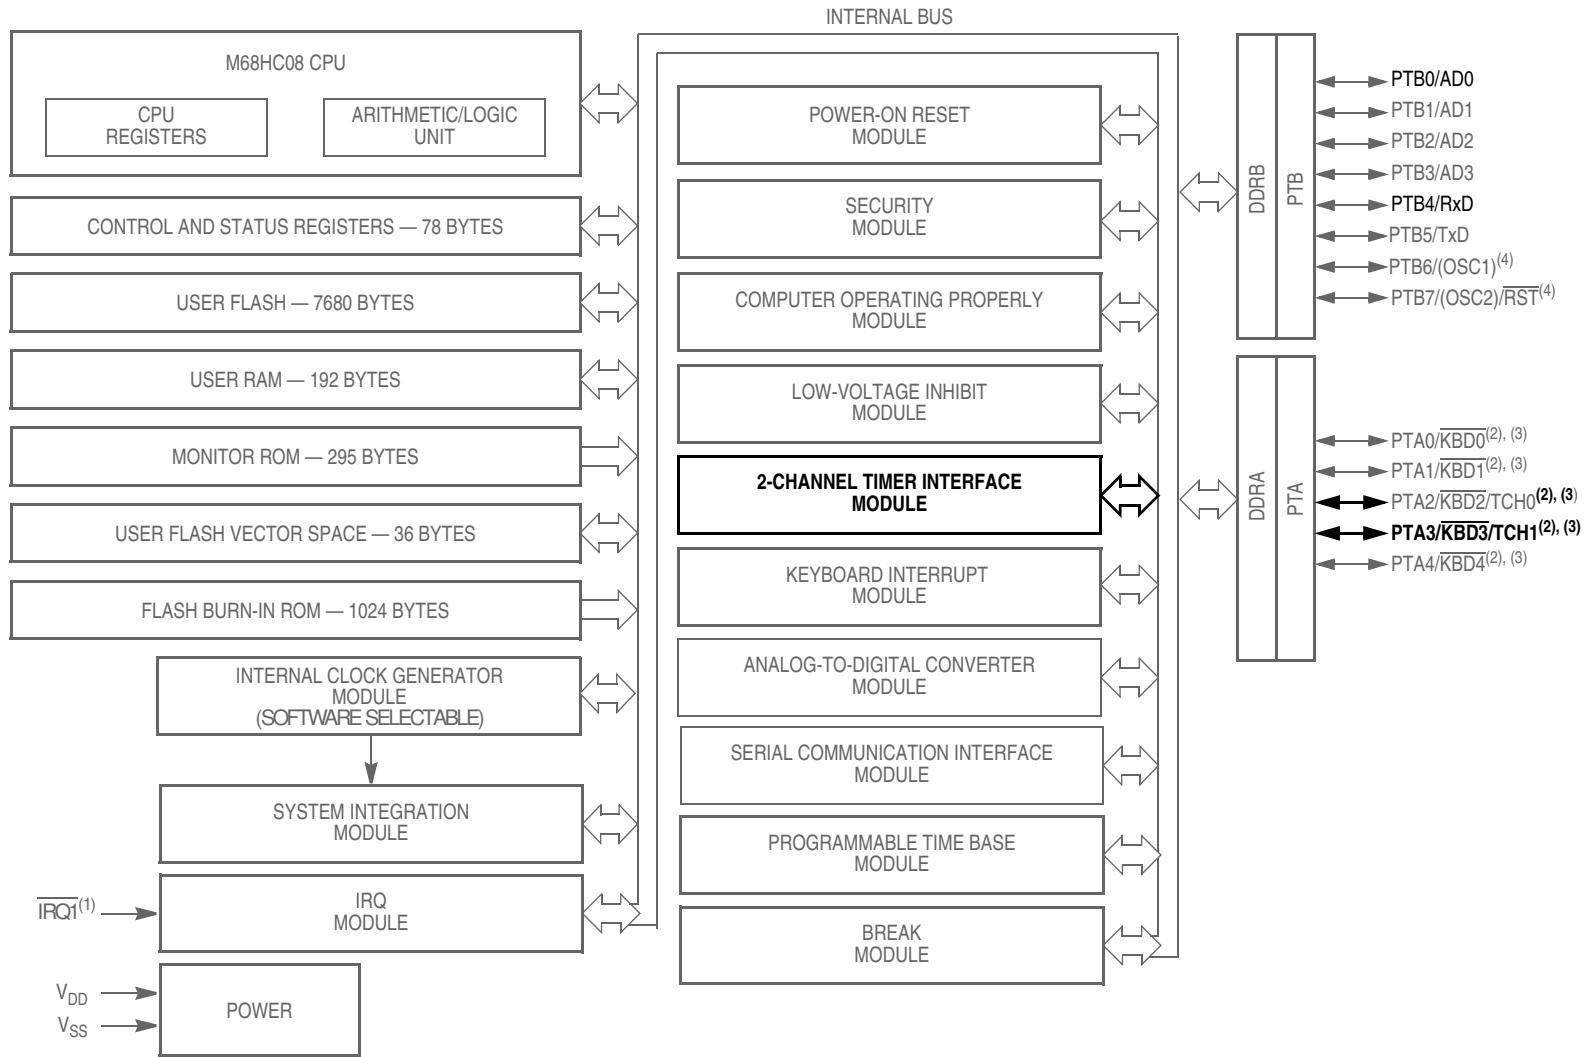

TIM Generic Pin Names:	<b>TCH0</b>	<b>TCH1</b>
Full TIM Pin Names:	PTA2/KBD2/TCH0	PTA3/KBD3/TCH1

### 15.4 Functional Description

[Figure 15-2](#) shows the structure of the TIM. The central component of the TIM is the 16-bit TIM counter that can operate as a free-running counter or a modulo up-counter. The TIM counter provides the timing reference for the input capture and output compare functions. The TIM counter modulo registers, TMODH and TMODL, control the modulo value of the TIM counter. Software can read the TIM counter value at any time without affecting the counting sequence.

The two TIM channels are programmable independently as input capture or output compare channels.

[Figure 15-3](#) summarizes the timer registers.

Notes:

1. Pin contains integrated pullup resistor
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.

**Figure 15-3. TIM I/O Register Summary (Continued)**

### 15.4.1 TIM Counter Prescaler

The TIM clock source can be one of the seven prescaler outputs. The prescaler generates seven clock rates from the internal bus clock. The prescaler select bits, PS2–PS0, in the TIM status and control register select the TIM clock source.

### 15.4.2 Input Capture

With the input capture function, the TIM can capture the time at which an external event occurs. When an active edge occurs on the pin of an input capture channel, the TIM latches the contents of the TIM counter into the TIM channel registers, TCHxH and TCHxL. The polarity of the active edge is programmable. Input captures can generate TIM CPU interrupt requests.

### 15.4.3 Output Compare

With the output compare function, the TIM can generate a periodic pulse with a programmable polarity, duration, and frequency. When the counter reaches the value in the registers of an output compare channel, the TIM can set, clear, or toggle the channel pin. Output compares can generate TIM CPU interrupt requests.

### 15.4.4 Unbuffered Output Compare

Any output compare channel can generate unbuffered output compare pulses as described in [15.4.3 Output Compare](#). The pulses are unbuffered because changing the output compare value requires writing the new value over the old value currently in the TIM channel registers.

An unsynchronized write to the TIM channel registers to change an output compare value could cause incorrect operation for up to two counter overflow periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that counter overflow period. Also, using a TIM overflow interrupt routine to write a new, smaller output compare value may cause the compare to be missed. The TIM may pass the new value before it is written.

Use these methods to synchronize unbuffered changes in the output compare value on channel x:

- When changing to a smaller value, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current output compare pulse. The interrupt routine has until the end of the counter overflow period to write the new value.
- When changing to a larger output compare value, enable TIM overflow interrupts and write the new value in the TIM overflow interrupt routine. The TIM overflow interrupt occurs at the end of the current counter overflow period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same counter overflow period.

### 15.4.5 Buffered Output Compare

Channels 0 and 1 can be linked to form a buffered output compare channel whose output appears on the TCH0 pin. The TIM channel registers of the linked pair alternately control the output.

Setting the MS0B bit in TIM channel 0 status and control register (TSC0) links channel 0 and channel 1. The output compare value in the TIM channel 0 registers initially controls the output on the TCH0 pin. Writing to the TIM channel 1 registers enables the TIM channel 1 registers to synchronously control the output after the TIM overflows. At each subsequent overflow, the TIM channel registers (0 or 1) that control the output are the 1s written to last. TSC0 controls and monitors the buffered output compare function, and TIM channel 1 status and control register (TSC1) is unused. While the MS0B bit is set, the channel 1 pin, TCH1, is available as a general-purpose I/O pin.

#### **NOTE**

*In buffered output compare operation, do not write new output compare values to the currently active channel registers. User software should track the currently active channel to prevent writing a new value to the active channel. Writing to the active channel registers is the same as generating unbuffered output compares.*

### 15.4.6 Pulse-Width Modulation (PWM)

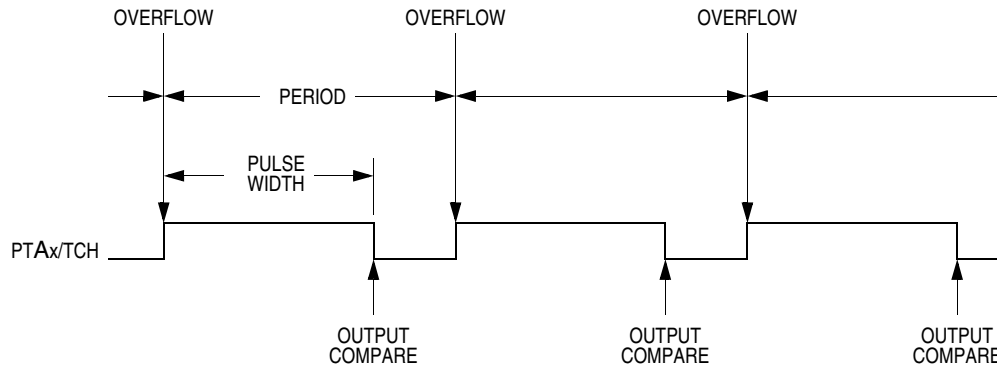

By using the toggle-on-overflow feature with an output compare channel, the TIM can generate a PWM signal. The value in the TIM counter modulo registers determines the period of the PWM signal. The channel pin toggles when the counter reaches the value in the TIM counter modulo registers. The time between overflows is the period of the PWM signal.

As [Figure 15-4](#) shows, the output compare value in the TIM channel registers determines the pulse width of the PWM signal. The time between overflow and output compare is the pulse width. Program the TIM

to clear the channel pin on output compare if the state of the PWM pulse is logic 1. Program the TIM to set the pin on overflow if the state of the PWM pulse is logic 0.

The value in the TIM counter modulo registers and the selected prescaler output determines the frequency of the PWM output. The frequency of an 8-bit PWM signal is variable in 256 increments. Writing \$00FF (255) to the TIM counter modulo registers produces a PWM period of 256 times the internal bus clock period if the prescaler select value is \$000. See [15.8.1 TIM Status and Control Register](#).

The value in the TIM channel registers determines the pulse width of the PWM output. The pulse width of an 8-bit PWM signal is variable in 256 increments. Writing \$0080 (128) to the TIM channel registers produces a duty cycle of 128/256 or 50 percent.

**Figure 15-4. PWM Period and Pulse Width**

### 15.4.7 Unbuffered PWM Signal Generation

Any output compare channel can generate unbuffered PWM pulses as described in [15.4.6 Pulse-Width Modulation \(PWM\)](#). The pulses are unbuffered because changing the pulse width requires writing the new pulse width value over the old value currently in the TIM channel registers.

An unsynchronized write to the TIM channel registers to change a pulse width value could cause incorrect operation for up to two PWM periods. For example, writing a new value before the counter reaches the old value but after the counter reaches the new value prevents any compare during that PWM period. Also, using a TIM overflow interrupt routine to write a new, smaller pulse width value may cause the compare to be missed. The TIM may pass the new value before it is written.

Use these methods to synchronize unbuffered changes in the PWM pulse width on channel x:

- When changing to a shorter pulse width, enable channel x output compare interrupts and write the new value in the output compare interrupt routine. The output compare interrupt occurs at the end of the current pulse. The interrupt routine has until the end of the PWM period to write the new value.
- When changing to a longer pulse width, enable TIM overflow interrupts and write the new value in the TIM overflow interrupt routine. The TIM overflow interrupt occurs at the end of the current PWM period. Writing a larger value in an output compare interrupt routine (at the end of the current pulse) could cause two output compares to occur in the same PWM period.

#### **NOTE**

*In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0 percent duty cycle generation and removes the ability of the channel to self-correct*

*in the event of software error or noise. Toggling on output compare also can cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

### 15.4.8 Buffered PWM Signal Generation

Channels 0 and 1 can be linked to form a buffered PWM channel whose output appears on the TCH0 pin. The TIM channel registers of the linked pair alternately control the pulse width of the output.

Setting the MS0B bit in TIM channel 0 status and control register (TSC0) links channel 0 and channel 1. The TIM channel 0 registers initially control the pulse width on the TCH0 pin. Writing to the TIM channel 1 registers enables the TIM channel 1 registers to synchronously control the pulse width at the beginning of the next PWM period. At each subsequent overflow, the TIM channel registers (0 or 1) that control the pulse width are the 1s written to last. TSC0 controls and monitors the buffered PWM function, and TIM channel 1 status and control register (TSC1) is unused. While the MS0B bit is set, the channel 1 pin, TCH1, is available as a general-purpose I/O pin.

#### NOTE

*In buffered PWM signal generation, do not write new pulse width values to the currently active channel registers. User software should track the currently active channel to prevent writing a new value to the active channel. Writing to the active channel registers is the same as generating unbuffered PWM signals.*

### 15.4.9 PWM Initialization

To ensure correct operation when generating unbuffered or buffered PWM signals, use this initialization procedure:

1. In the TIM status and control register (TSC):
  - a. Stop the TIM counter by setting the TIM stop bit, TSTOP.
  - b. Reset the TIM counter and prescaler by setting the TIM reset bit, TRST.
2. In the TIM counter modulo registers (TMODH and TMODL), write the value for the required PWM period.
3. In the TIM channel x registers (TCHxH and TCHxL), write the value for the required pulse width.
4. In TIM channel x status and control register (TSCx):
  - a. Write 0:1 (for unbuffered output compare or PWM signals) or 1:0 (for buffered output compare or PWM signals) to the mode select bits, MSxB and MSxA. See [Table 15-2](#).
  - b. Write 1 to the toggle-on-overflow bit, TOVx.
  - c. Write 1:0 (to clear output on compare) or 1:1 (to set output on compare) to the edge/level select bits, ELSxB and ELSxA. The output action on compare must force the output to the complement of the pulse width level. See [Table 15-2](#).

#### NOTE

*In PWM signal generation, do not program the PWM channel to toggle on output compare. Toggling on output compare prevents reliable 0 percent duty cycle generation and removes the ability of the channel to self-correct in the event of software error or noise. Toggling on output compare can also cause incorrect PWM signal generation when changing the PWM pulse width to a new, much larger value.*

5. In the TIM status control register (TSC), clear the TIM stop bit, TSTOP.

Setting MS0B links channels 0 and 1 and configures them for buffered PWM operation. The TIM channel 0 registers (TCH0H and TCH0L) initially control the buffered PWM output. TIM status control register 0 (TSCR0) controls and monitors the PWM signal from the linked channels.

Clearing the toggle-on-overflow bit, TOVx, inhibits output toggles on TIM overflows. Subsequent output compares try to force the output to a state it is already in and have no effect. The result is a 0 percent duty cycle output.

Setting the channel x maximum duty cycle bit (CHxMAX) and setting the TOVx bit generates a 100 percent duty cycle output. See [15.8.4 TIM Channel Status and Control Registers](#).

## 15.5 Interrupts

These TIM sources can generate interrupt requests:

- TIM overflow flag (TOF) — The timer overflow flag (TOF) bit is set when the TIM counter reaches the modulo value programmed in the TIM counter modulo registers. The TIM overflow interrupt enable bit, TOIE, enables TIM overflow interrupt requests. TOF and TOIE are in the TIM status and control registers.
- TIM channel flags (CH1F and CH0F) — The CHxF bit is set when an input capture or output compare occurs on channel x. Channel x TIM CPU interrupt requests are controlled by the channel x interrupt enable bit, CHxIE. Channel x TIM CPU interrupt requests are enabled when CHxIE = 1. CHxF and CHxIE are in the TIM channel x status and control register.

## 15.6 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

### 15.6.1 Wait Mode

The TIM remains active after the execution of a WAIT instruction. In wait mode the TIM registers are not accessible by the CPU. Any enabled CPU interrupt request from the TIM can bring the MCU out of wait mode.

If TIM functions are not required during wait mode, reduce power consumption by stopping the TIM before executing the WAIT instruction.

### 15.6.2 Stop Mode

The TIM is inactive after the execution of a STOP instruction. The STOP instruction does not affect register conditions or the state of the TIM counter. TIM operation resumes when the MCU exits stop mode after an external interrupt.

## 15.7 I/O Signals

Port A shares two of its pins with the TIM, PTA3/ $\overline{\text{KBD3}}$ /TCH1 and PTA2/ $\overline{\text{KBD2}}$ /TCH0. Each channel input/output (I/O) pin is programmable independently as an input capture pin or an output compare pin. TCH0 can be configured as buffered output compare or buffered PWM pins.

## 15.8 I/O Registers

These I/O registers control and monitor operation of the TIM:

- TIM status and control register (TSC)
- TIM control registers (TCNTH and TCNTL)
- TIM counter modulo registers (TMODH and TMODL)
- TIM channel status and control registers (TSC0 and TSC1)
- TIM channel registers (TCH0H and TCH0L, TCH1H and TCH1L)

### 15.8.1 TIM Status and Control Register

The TIM status and control register (TSC):

- Enables TIM overflow interrupts
- Flags TIM overflows
- Stops the TIM counter
- Resets the TIM counter
- Prescales the TIM counter clock

**Figure 15-5. TIM Status and Control Register (TSC)**

#### TOF — TIM Overflow Flag Bit

This read/write flag is set when the TIM counter reaches the modulo value programmed in the TIM counter modulo registers. Clear TOF by reading the TIM status and control register when TOF is set and then writing a 0 to TOF. If another TIM overflow occurs before the clearing sequence is complete, then writing 0 to TOF has no effect. Therefore, a TOF interrupt request cannot be lost due to inadvertent clearing of TOF. Reset clears the TOF bit. Writing a 1 to TOF has no effect.

1 = TIM counter has reached modulo value.

0 = TIM counter has not reached modulo value.

#### TOIE — TIM Overflow Interrupt Enable Bit

This read/write bit enables TIM overflow interrupts when the TOF bit becomes set. Reset clears the TOIE bit.

1 = TIM overflow interrupts enabled

0 = TIM overflow interrupts disabled

#### TSTOP — TIM Stop Bit

This read/write bit stops the TIM counter. Counting resumes when TSTOP is cleared. Reset sets the TSTOP bit, stopping the TIM counter until software clears the TSTOP bit.

1 = TIM counter stopped

0 = TIM counter active

#### **NOTE**

*Do not set the TSTOP bit before entering wait mode if the TIM is required to exit wait mode.*

**TRST — TIM Reset Bit**

Setting this write-only bit resets the TIM counter and the TIM prescaler. Setting TRST has no effect on any other registers. Counting resumes from \$0000. TRST is cleared automatically after the TIM counter is reset and always reads as 0. Reset clears the TRST bit.

- 1 = Prescaler and TIM counter cleared
- 0 = No effect

**NOTE**

*Setting the TSTOP and TRST bits simultaneously stops the TIM counter at a value of \$0000.*

**PS2–PS0 — Prescaler Select Bits**

These read/write bits select one of the seven prescaler outputs as the input to the TIM counter as Table 15-2 shows. Reset clears the PS2–PS0 bits.

**Table 15-2. Prescaler Selection**

PS2–PS0	TIM Clock Source
000	Internal bus clock ÷ 1
001	Internal bus clock ÷ 2
010	Internal bus clock ÷ 4
011	Internal bus clock ÷ 8
100	Internal bus clock ÷ 16
101	Internal bus clock ÷ 32
110	Internal bus clock ÷ 64
111	Not available

**15.8.2 TIM Counter Registers**

The two read-only TIM counter registers (TCNTH and TCNTL) contain the high and low bytes of the value in the TIM counter. Reading the high byte (TCNTH) latches the contents of the low byte (TCNTL) into a buffer. Subsequent reads of TCNTH do not affect the latched TCNTL value until TCNTL is read. Reset clears the TIM counter registers. Setting the TIM reset bit (TRST) also clears the TIM counter registers.

**Figure 15-6. TIM Counter Registers (TCNTH and TCNTL)**

### 15.8.3 TIM Counter Modulo Registers

The read/write TIM modulo registers (TMODH and TMODL) contain the modulo value for the TIM counter. When the TIM counter reaches the modulo value, the overflow flag (TOF) becomes set, and the TIM counter resumes counting from \$0000 at the next timer clock. Writing to the high byte (TMODH) inhibits the TOF bit and overflow interrupts until the low byte (TMODL) is written. Reset sets the TIM counter modulo registers.

Register name and address: TMODH — \$0023

Write:								
Reset:	1	1	1	1	1	1	1	1

**Figure 15-7. TIM Counter Modulo Registers (TMODH and TMODL)**

**NOTE**

*Reset the TIM counter before writing to the TIM counter modulo registers.*

### 15.8.4 TIM Channel Status and Control Registers

Each of the TIM channel status and control registers (TSC0 and TSC1):

- Flags input captures and output compares
- Enables input capture and output compare interrupts
- Selects input capture, output compare, or PWM operation
- Selects high, low, or toggling output on output compare
- Selects rising edge, falling edge, or any edge as the active input capture trigger
- Selects output toggling on TIM overflow
- Selects 0 percent and 100 percent PWM duty cycle
- Selects buffered or unbuffered output compare/PWM operation

Register name and address: TSC0 — \$0025								
	Bit 7	6	5	4	3	2	1	Bit 0

**Figure 15-8. TIM Channel Status and Control Registers (TSC0 and TSC1)**

### CHxF — Channel x Flag Bit

When channel x is an input capture channel, this read/write bit is set when an active edge occurs on the channel x pin. When channel x is an output compare channel, CHxF is set when the value in the TIM counter registers matches the value in the TIM channel x registers.

When TIM CPU interrupt requests are enabled (CHxIE = 1), clear CHxF by reading TIM channel x status and control register with CHxF set and then writing a 0 to CHxF. If another interrupt request occurs before the clearing sequence is complete, then writing 0 to CHxF has no effect. Therefore, an interrupt request cannot be lost due to inadvertent clearing of CHxF.

Reset clears the CHxF bit. Writing a 1 to CHxF has no effect.

- 1 = Input capture or output compare on channel x
- 0 = No input capture or output compare on channel x

### CHxIE — Channel x Interrupt Enable Bit

This read/write bit enables TIM CPU interrupts on channel x. Reset clears the CHxIE bit.

- 1 = Channel x CPU interrupt requests
- 0 = Channel x CPU interrupt requests disabled

### MS0B — Mode Select Bit B

This read/write bit selects buffered output compare/PWM operation. MS0B exists only in the TIM channel 0 status and control register.

Setting MS0B disables the channel 1 status and control register and reverts TCH1 to general-purpose I/O. Reset clears the MSxB bit.

- 1 = Buffered output compare/PWM operation enabled
- 0 = Buffered output compare/PWM operation disabled

### MSxA — Mode Select Bit A

When ELSxB:A ≠ 00, this read/write bit selects either input capture operation or unbuffered output compare/PWM operation. See [Table 15-3](#).

- 1 = Unbuffered output compare/PWM operation
- 0 = Input capture operation

When ELSxB:A = 00, this read/write bit selects the initial output level of the TCHx pin. See [Table 15-3](#). Reset clears the MSxA bit.

- 1 = Initial output level low
- 0 = Initial output level high

#### **NOTE**

*Before changing a channel function by writing to the MS0B or MSxA bit, set the TSTOP and TRST bits in the TIM status and control register (TSC).*

### ELSxB and ELSxA — Edge/Level Select Bits

When channel x is an input capture channel, these read/write bits control the active edge-sensing logic on channel x.

When channel x is an output compare channel, ELSxB and ELSxA control the channel x output behavior when an output compare occurs.

When ELSxB and ELSxA are both clear, channel x is not connected to port A, and pin PTAx/TCHx is available as a general-purpose I/O pin. [Table 15-3](#) shows how ELSxB and ELSxA work. Reset clears the ELSxB and ELSxA bits.

**Table 15-3. Mode, Edge, and Level Selection**

MSxB	MSxA	ELSxB	ELSxA	Mode	Configuration
X	0	0	0	Output preset	Pin under port control; initial output level high
X	1	0	0		Pin under port control; initial output level low
0	0	0	1	Input capture	Capture on rising edge only
0	0	1	0		Capture on falling edge only
0	0	1	1		Capture on rising or falling edge
0	1	0	0	Output compare or PWM	Software compare only
0	1	0	1		Toggle output on compare
0	1	1	0		Clear output on compare
0	1	1	1		Set output on compare
1	X	0	1	Buffered output compare or buffered PWM	Toggle output on compare
1	X	1	0		Clear output on compare
1	X	1	1		Set output on compare

**NOTE**

*Before enabling a TIM channel register for input capture operation, make sure that the PTAx/TCHx pin is stable for at least two bus clocks.*

**TOVx — Toggle On Overflow Bit**

When channel x is an output compare channel, this read/write bit controls the behavior of the channel x output when the TIM counter overflows. When channel x is an input capture channel, TOVx has no effect. Reset clears the TOVx bit.

1 = Channel x pin toggles on TIM counter overflow.

0 = Channel x pin does not toggle on TIM counter overflow.

**NOTE**

*When TOVx is set, a TIM counter overflow takes precedence over a channel x output compare if both occur at the same time.*

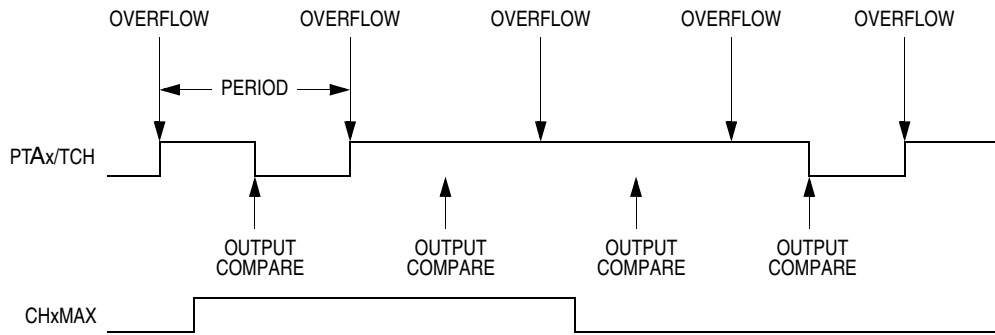

**CHxMAX — Channel x Maximum Duty Cycle Bit**

When the TOVx bit is at 1 and clear output on compare is selected, setting the CHxMAX bit forces the duty cycle of buffered and unbuffered PWM signals to 100 percent. As [Figure 15-9](#) shows, the CHxMAX bit takes effect in the cycle after it is set or cleared. The output stays at 100 percent duty cycle level until the cycle after CHxMAX is cleared.

**NOTE**

*The PWM 0 percent duty cycle is defined as output low all of the time. To generate the 0 percent duty cycle, select clear output on compare and then clear the TOVx bit (CHxMAX = 0). The PWM 100 percent duty cycle is defined as output high all of the time. To generate the 100 percent duty cycle, use the CHxMAX bit in the TSCx register.*

## Timer Interface Module (TIM)

**Figure 15-9. CHxMAX Latency**

### 15.8.5 TIM Channel Registers

These read/write registers (TCH0H/L and TCH1H/L) contain the captured TIM counter value of the input capture function or the output compare value of the output compare function. The state of the TIM channel registers after reset is unknown.

In input capture mode ( $MSxB:MSxA = 0:0$ ), reading the high byte of the TIM channel x registers (TCHxH) inhibits input captures until the low byte (TCHxL) is read.

In output compare mode ( $MSxB:MSxA \neq 0:0$ ), writing to the high byte of the TIM channel x registers (TCHxH) inhibits output compares until the low byte (TCHxL) is written.

**Figure 15-10. TIM Channel Registers (TCH0H/L and TCH1H/L)**

# Chapter 16

## Development Support

### 16.1 Introduction

This section describes the break module, the monitor read-only memory (MON), and the monitor mode entry methods.

### 16.2 Break Module (BRK)

The break module can generate a break interrupt that stops normal program flow at a defined address to enter a background program.

Features include:

- Accessible input/output (I/O) registers during the break interrupt
- Central processor unit (CPU) generated break interrupts
- Software generated break interrupts
- Computer operating properly (COP) disabling during break interrupts

#### 16.2.1 Functional Description

When the internal address bus matches the value written in the break address registers, the break module issues a breakpoint signal to the CPU. The CPU then loads the instruction register with a software interrupt instruction (SWI) after completion of the current CPU instruction. The program counter vectors to \$FFFC and \$FFFD (\$FEFC and \$FEFD in monitor mode).

These events can cause a break interrupt to occur:

- A CPU-generated address (the address in the program counter) matches the contents of the break address registers.
- Software writes a 1 to the BRKA bit in the break status and control register.

When a CPU-generated address matches the contents of the break address registers, the break interrupt begins after the CPU completes its current instruction. A return-from-interrupt instruction (RTI) in the break routine ends the break interrupt and returns the MCU to normal operation. [Figure 16-1](#) shows the structure of the break module.

##### 16.2.1.1 Flag Protection During Break Interrupts

The BCFE bit in the SIM break flag control register (SBFCR) enables software to clear status bits during the break state.

Figure 16-1. Break Module Block Diagram

= Unimplemented      R = Reserved

Figure 16-2. I/O Register Summary

### 16.2.1.2 CPU During Break Interrupts

The CPU starts a break interrupt by:

- Loading the instruction register with the SWI instruction
- Loading the program counter with \$FFFC and \$FFFD (\$FEFC and \$FEFD in monitor mode)

The break interrupt begins after completion of the CPU instruction in progress. If the break address register match occurs on the last cycle of a CPU instruction, the break interrupt begins immediately.

### 16.2.1.3 TIM1 and TIM2 During Break Interrupts

A break interrupt stops the timer counters.

### 16.2.1.4 COP During Break Interrupts

The COP is disabled during a break interrupt when BDCOP bit is set in break auxiliary register (BRKAR).

## 16.2.2 Break Module Registers

These registers control and monitor operation of the break module:

- Break status and control register (BRKSCR)
- Break address register high (BRKH)
- Break address register low (BRKL)
- SIM break status register (SBSR)
- SIM break flag control register (SBFCR)

### 16.2.2.1 Break Status and Control Register

The break status and control register (BRKSCR) contains break module enable and status bits.

Address: \$FE0B

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	BRKE	BRKA	0	0	0	0	0	0
Write:								
Reset:	0	0	0	0	0	0	0	0

 = Unimplemented

**Figure 16-3. Break Status and Control Register (BRKSCR)**

#### BRKE — Break Enable Bit

This read/write bit enables breaks on break address register matches. Clear BRKE by writing a 0 to bit 7. Reset clears the BRKE bit.

- 1 = Breaks enabled on 16-bit address match
- 0 = Breaks disabled on 16-bit address match

#### BRKA — Break Active Bit

This read/write status and control bit is set when a break address match occurs. Writing a 1 to BRKA generates a break interrupt. Clear BRKA by writing a 0 to it before exiting the break routine. Reset clears the BRKA bit.

- 1 = When read, break address match
- 0 = When read, no break address match

### 16.2.2.2 Break Address Registers

The break address registers (BRKH and BRKL) contain the high and low bytes of the desired breakpoint address. Reset clears the break address registers.

Address: \$FE09

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 15	14	13	12	11	10	9	Bit 8
Write:								
Reset:	0	0	0	0	0	0	0	0

**Figure 16-4. Break Address Register High (BRKH)**

Address: \$FE0A

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	Bit 7	6	5	4	3	2	1	Bit 0
Write:								
Reset:	0	0	0	0	0	0	0	0

**Figure 16-5. Break Address Register Low (BRKL)**

### 16.2.2.3 Break Status Register

The break status register (SBSR) contains a flag to indicate that a break caused an exit from wait mode. The flag is useful in applications requiring a return to wait mode after exiting from a break interrupt.

Address: \$FE00

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	0	0	0	1	0	0	BW	0
Write:	R	R	R	R	R	R	NOTE	R
Reset:	0	0	0	1	0	0	0	0

Note: Writing a 0 clears BW. R = Reserved

**Figure 16-6. SIM Break Status Register (SBSR)**

#### BW — Break Wait Bit

This read/write bit is set when a break interrupt causes an exit from wait mode. Clear BW by writing a 0 to it. Reset clears BW.

- 1 = Break interrupt during wait mode
- 0 = No break interrupt during wait mode

BW can be read within the break interrupt routine. The user can modify the return address on the stack by subtracting 1 from it.

### 16.2.2.4 Break Flag Control Register

The break flag control register (SBFCR) contains a bit that enables software to clear status bits while the MCU is in a break state.

**Figure 16-7. SIM Break Flag Control Register (SBFCR)**

#### BCFE — Break Clear Flag Enable Bit

This read/write bit enables software to clear status bits by accessing status registers while the MCU is in a break state. To clear status bits during the break state, the BCFE bit must be set.

- 1 = Status bits clearable during break
- 0 = Status bits not clearable during break

### 16.2.2.5 Break Auxiliary Register

The break auxiliary register (BRKAR) contains a bit that enables software to disable the COP while the MCU is in a state of break interrupt with monitor mode.

**Figure 16-8. Break Auxiliary Register (BRKAR)**

#### BDCOP — Break Disable COP Bit

This read/write bit disables the COP during a break interrupt. Reset clears the BDCOP bit.

- 1 = COP disabled during break interrupt
- 0 = COP enabled during break interrupt

## 16.2.3 Low-Power Modes

The WAIT and STOP instructions put the MCU in low power-consumption standby modes.

### 16.2.3.1 Wait Mode

If enabled, the break module is active in wait mode. In the break routine, the user can subtract one from the return address on the stack if SBSW is set. Clear the BW bit by writing 0 to it.

### 16.2.3.2 Stop Mode

A break interrupt causes exit from stop mode and sets the BW bit in the break status register.

## 16.3 Monitor ROM (MON)

The monitor ROM allows complete testing of the microcontroller unit (MCU) through a single-wire interface with a host computer. Monitor mode entry can be achieved without use of the higher test voltage,  $V_{TST}$ , as long as vector addresses \$FFFE and \$FFFF are blank, thus reducing hardware requirements for in-circuit programming.

Features include:

- Normal user-mode pin functionality
- One pin dedicated to serial communication between monitor ROM and host computer
- Standard mark/space non-return-to-zero (NRZ) communication with host computer
- Execution of code in random-access memory (RAM) or FLASH
- FLASH memory security<sup>(1)</sup>
- FLASH memory programming interface
- Monitor mode entry without high voltage,  $V_{TST}$ , if reset vector is blank (\$FFFE and \$FFFF contain \$FF)
- Standard monitor mode entry if high voltage,  $V_{TST}$ , is applied to  $\overline{IRQ}$

### 16.3.1 Functional Description

The monitor ROM receives and executes commands from a host computer via a standard RS-232 interface. Simple monitor commands can access any memory address. In monitor mode, the microcontroller unit (MCU) can execute host-computer code in RAM while all MCU pins retain normal operating mode functions. All communication between the host computer and the MCU is through the PTA0 pin. A level-shifting and multiplexing interface is required between PTA0 and the host computer. PTA0 is used in a wired-OR configuration and requires a pullup resistor.

#### 16.3.1.1 Monitor Mode Entry

There are two methods for entering monitor mode. The first is the traditional M68HC08 method where  $V_{TST}$  is applied to  $\overline{IRQ1}$  and the mode pins are configured appropriately. A second method, intended for in-circuit programming applications, will force entry into monitor mode without requiring high voltage on the  $\overline{IRQ1}$  pin when the reset vector locations of the FLASH are erased (\$FF).

Both of these methods require that the PTA1 pin be pulled low for the first 24 CGMXCLK cycles after the part comes out of reset. This check is used by the monitor code to configure the MCU for serial communication.

#### 16.3.1.2 Normal Monitor Mode

Normal monitor mode is useful for MCU evaluation, factory testing, and development tool programming operation. [Figure 16-9](#) shows an example circuit used for normal monitor mode. [Table 16-1](#) shows the pin conditions for entering this mode.

1. No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the FLASH difficult for unauthorized users.

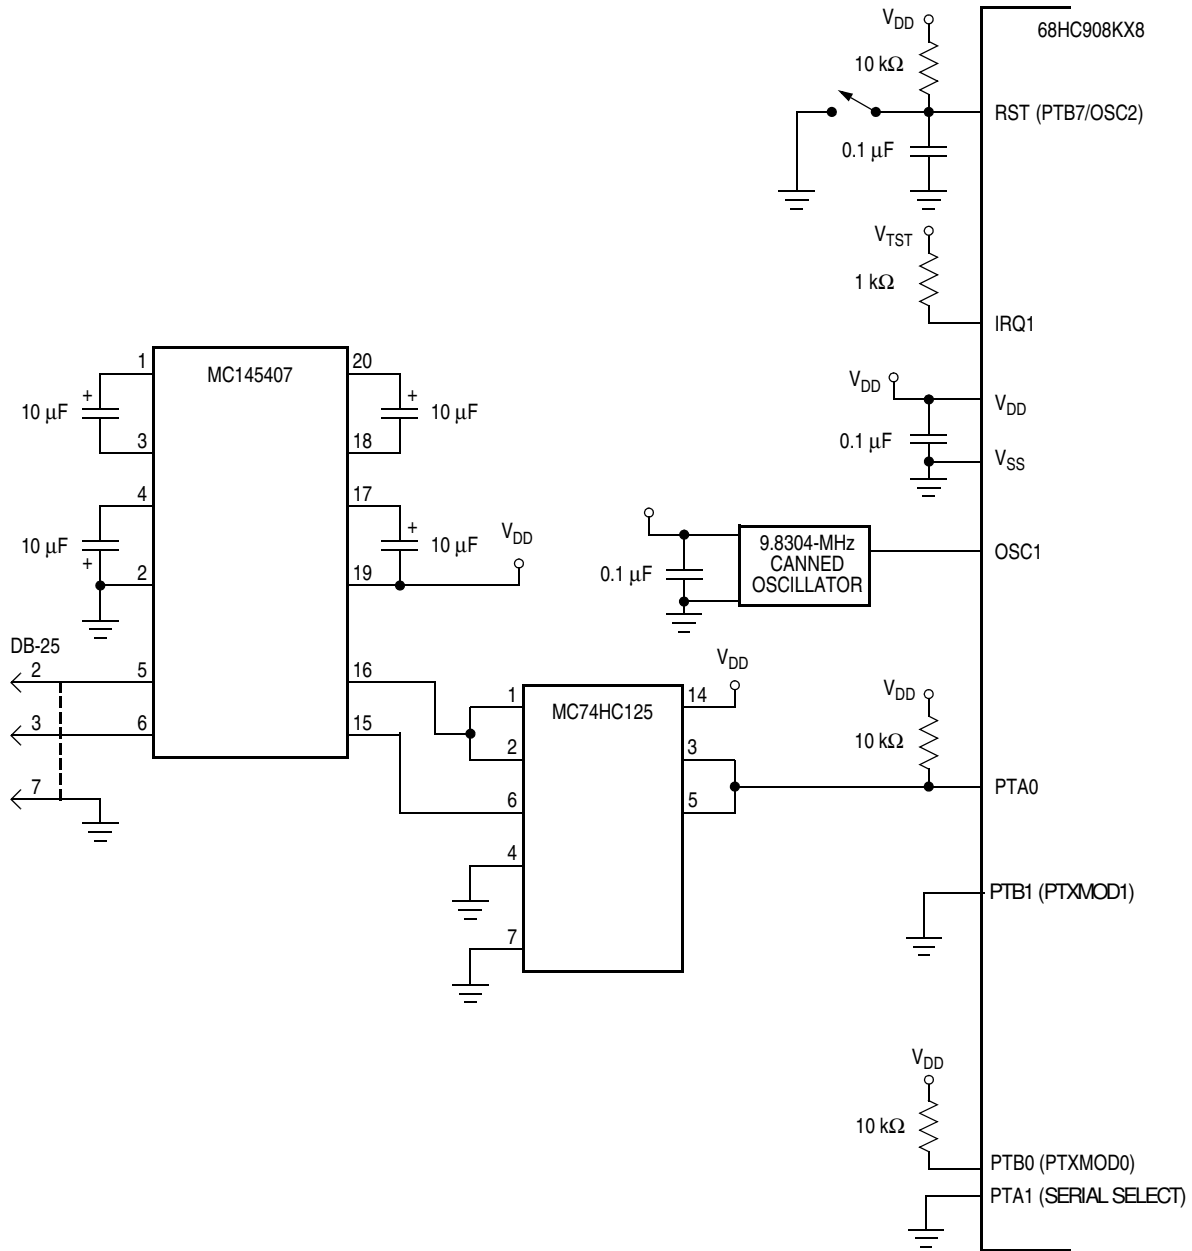

Figure 16-9. Normal Monitor Mode Circuit

Table 16-1. Monitor Mode Entry

\$FFFE/ \$FFFF	$\overline{\text{IRQ1}}$ Pin	PTB1 Pin (PTXMOD1)	PTB0 Pin (PTXMOD0)	PTA1 Pin	PTA0 Pin	CGMOUT	Bus Frequency ( $f_{OP}$ )
X	$V_{TST}$	0	1	0	1	$\frac{\text{CGMXCLK}}{2}$	$\frac{\text{CGMOUT}}{2}$
\$FF blank	$V_{DD}$	X	X	0	1	$\frac{\text{CGMXCLK}}{2}$	$\frac{\text{CGMOUT}}{2}$

**NOTE**

*PTA1 = 0 and PTA0 = 1 allow normal serial communications. PTA1 = 1 allows parallel communications during security code entry. (For parallel communications, configure PTA0 = 0 or PTA0 = 1.)*

The MCU initially comes out of reset using the external clock for its clock source. This overrides the user mode operation of the oscillator circuits where the part comes up using the internally generated oscillator. Running from an external clock allows the MCU, using an appropriate frequency clock source, to communicate with host software at standard baud rates.

**NOTE**

*While the voltage on  $\overline{IRQ1}$  is at  $V_{TST}$ , the ICG module is bypassed and the external square-wave clock becomes the clock source. Dropping  $\overline{IRQ1}$  to below  $V_{TST}$  will remove the bypass and the MCU will revert to the clock source selected by the ICG (as determined by the settings in the ICG registers).*

*In normal monitor mode with  $V_{TST}$  on  $\overline{IRQ1}$ , the MCU alters PTB7/(OSC2)/ $\overline{RST}$  to function as a  $\overline{RST}$  pin. This is useful for testing the MCU. Dropping  $\overline{IRQ1}$  voltage to below  $V_{TST}$  will revert PTB7/(OSC2)/ $\overline{RST}$  to its user mode function.*

The computer operating properly (COP) module is disabled in normal monitor mode whenever  $V_{TST}$  is applied to the  $\overline{IRQ1}$  pin. If the voltage on  $\overline{IRQ1}$  is less than  $V_{TST}$ , the COP module is controlled by the COPD configuration bit.

**16.3.1.3 Forced Monitor Mode**

If the voltage applied to the  $\overline{IRQ1}$  is less than  $V_{TST}$ , the MCU will come out of reset in user mode. The MENRST module is monitoring the reset vector fetches and will assert an internal reset if it detects that the reset vectors are erased (\$FF). When the MCU comes out of reset, it is forced into monitor mode without requiring high voltage on the  $\overline{IRQ1}$  pin.

Once out of reset, the monitor code is initially executing off the internal clock at its default frequency. The monitor code reconfigures the ICG module to use the external square-wave clock source. Switching to an external clock source allows the MCU, using an appropriate clock frequency, to communicate with host software at standard baud rates.

The COP module is disabled in forced monitor mode. Any reset other than a power-on reset (POR) will automatically force the MCU to come back to the forced monitor mode.

**16.3.1.4 Monitor Mode Vectors**

Monitor mode uses alternate vectors for reset and SWI interrupts. The alternate vectors are in the \$FE page instead of the \$FF page and allow code execution from the internal monitor firmware instead of user code. [Table 16-2](#) shows vector differences between user mode and monitor mode.

**Table 16-2. Monitor Mode Vector Relocation**

Modes	Reset Vector High	Reset Vector Low	SWI Vector High	SWI Vector Low
User	\$FFFE	\$FFFF	\$FFFC	\$FFFD
Monitor	\$FEFE	\$FEFF	\$FEFC	\$FEFD

### 16.3.1.5 Data Format

The MCU waits for the host to send eight security bytes (see [16.3.2 Security](#)). After the security bytes, the MCU sends a break signal (10 consecutive 0s) to the host computer, indicating that it is ready to receive a command.

Communication with the monitor ROM is in standard non-return-to-zero (NRZ) mark/space data format. Transmit and receive baud rates must be identical.

**Figure 16-10. Monitor Data Format**

### 16.3.1.6 Break Signal

A start bit (0) followed by nine 0 bits is a break signal. When the monitor receives a break signal, it drives the PTA0 pin high for the duration of two bits and then echoes back the break signal.

**Figure 16-11. Break Transaction**

### 16.3.1.7 Baud Rate

The communication baud rate is controlled by the CGMXCLK frequency output of the internal clock generator module.

### 16.3.1.8 Force Monitor Mode

In forced monitor mode, the baud rate is fixed at  $\text{CGMXCLK}/1024$ . A CGMXCLK frequency of 4.9152 MHz results in a 4800 baud rate. A 9.8304-MHz frequency produces a 9600 baud rate.

### 16.3.1.9 Normal Monitor Mode

In normal monitor mode, the communication baud rate is controlled by the CGMXCLK frequency output of the internal clock generator module. [Table 16-3](#) lists CGMXCLK frequencies required to achieve standard baud rates. Other standard baud rates can be accomplished using other clock frequencies. The internal clock can be used as the clock source by programming the internal clock generator registers however, monitor mode will always be entered using the external clock as the clock source.

**Table 16-3. Normal Monitor Mode Baud Rate Selection**

CGMXCLK Frequency (MHz)	Baud Rate
9.8304	9600

### 16.3.1.10 Commands

The monitor ROM firmware uses these commands:

- READ, read memory
- WRITE, write memory
- IREAD, indexed read
- IWRITE, indexed write
- READSP, read stack pointer
- RUN, run user program

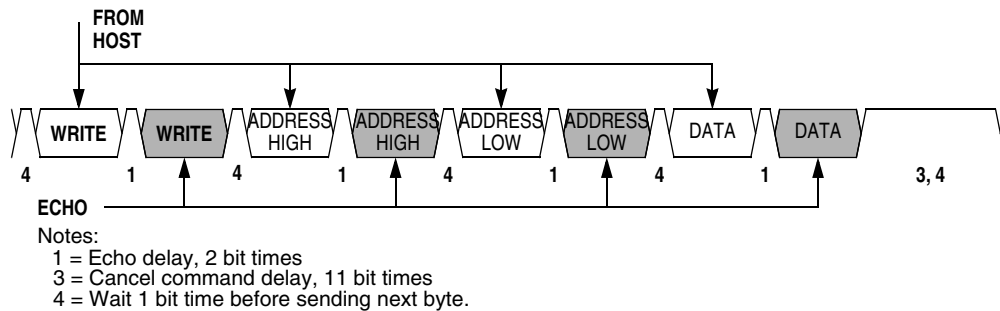

The monitor ROM firmware echoes each received byte back to the PTA0 pin for error checking. An 11-bit delay at the end of each command allows the host to send a break character to cancel the command. A delay of two bit times occurs before each echo and before READ, IREAD, or READSP data is returned. The data returned by a read command appears after the echo of the last byte of the command.

**NOTE**

*Wait one bit time after each echo before sending the next byte.*

**Figure 16-12. Read Transaction**

**Figure 16-13. Write Transaction**

A brief description of each monitor mode command is given in [Table 16-4](#) through [Table 16-9](#).

**Table 16-4. READ (Read Memory) Command**

<b>Description</b>	Read byte from memory
<b>Operand</b>	2-byte address in high-byte:low-byte order
<b>Data Returned</b>	Returns contents of specified address
<b>Opcode</b>	\$4A
<b>Command Sequence</b>	
<p>The diagram illustrates the command sequence for the READ command. It starts with a 'SENT TO MONITOR' signal pointing to the first 'READ' and the two 'ADDRESS HIGH' bytes. The sequence of bytes is: READ, READ, ADDRESS HIGH, ADDRESS HIGH, ADDRESS LOW, ADDRESS LOW, and DATA. An 'ECHO' signal points to the second 'READ', the two 'ADDRESS LOW' bytes, and the 'DATA' byte. A 'RETURN' signal is shown at the end of the sequence.</p>	

**Table 16-5. WRITE (Write Memory) Command**

<b>Description</b>	Write byte to memory
<b>Operand</b>	2-byte address in high-byte:low-byte order; low byte followed by data byte
<b>Data Returned</b>	None
<b>Opcode</b>	\$49
<b>Command Sequence</b>	
<p>The diagram illustrates the command sequence for the WRITE command. It starts with a 'FROM HOST' signal pointing to the first 'WRITE' and the two 'ADDRESS HIGH' bytes. The sequence of bytes is: WRITE, WRITE, ADDRESS HIGH, ADDRESS HIGH, ADDRESS LOW, ADDRESS LOW, DATA, and DATA. An 'ECHO' signal points to the second 'WRITE', the two 'ADDRESS LOW' bytes, and the two 'DATA' bytes.</p>	

**Table 16-6. IREAD (Indexed Read) Command**

<b>Description</b>	Read next 2 bytes in memory from last address accessed
<b>Operand</b>	2-byte address in high byte:low byte order
<b>Data Returned</b>	Returns contents of next two addresses
<b>Opcode</b>	\$1A
<b>Command Sequence</b>	
<p>The diagram illustrates the command sequence for the IREAD command. It starts with a 'FROM HOST' signal pointing to the first 'IREAD'. The sequence of bytes is: IREAD, IREAD, DATA, and DATA. An 'ECHO' signal points to the second 'IREAD'. A 'RETURN' signal is shown at the end of the sequence.</p>	

**Table 16-7. IWRITE (Indexed Write) Command**

<b>Description</b>	Write to last address accessed + 1
<b>Operand</b>	Single data byte
<b>Data Returned</b>	None
<b>Opcode</b>	\$19
<b>Command Sequence</b>	

A sequence of IREAD or IWRITE commands can access a block of memory sequentially over the full 64-Kbyte memory map.

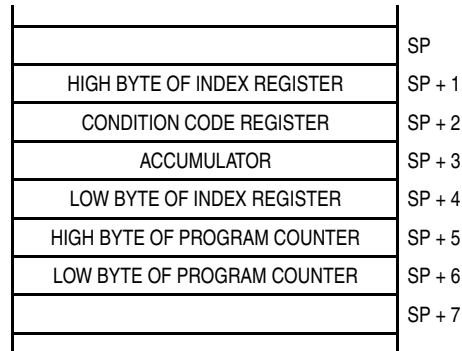

**Table 16-8. READSP (Read Stack Pointer) Command**

<b>Description</b>	Reads stack pointer
<b>Operand</b>	None
<b>Data Returned</b>	Returns incremented stack pointer value (SP + 1) in high-byte:low-byte order
<b>Opcode</b>	\$0C
<b>Command Sequence</b>	

**Table 16-9. RUN (Run User Program) Command**

<b>Description</b>	Executes PULH and RTI instructions
<b>Operand</b>	None
<b>Data Returned</b>	None
<b>Opcode</b>	\$28
<b>Command Sequence</b>	

The MCU executes the SWI and PSHH instructions when it enters monitor mode. The RUN command tells the MCU to execute the PULH and RTI instructions. Before sending the RUN command, the host can modify the stacked CPU registers to prepare to run the host program. The READSP command returns the incremented stack pointer value, SP + 1. The high and low bytes of the program counter are at addresses SP + 5 and SP + 6.

**Figure 16-14. Stack Pointer at Monitor Mode Entry**

### 16.3.2 Security

A security feature discourages unauthorized reading of FLASH locations while in monitor mode. The host can bypass the security feature at monitor mode entry by sending eight security bytes that match the bytes at locations \$FFF6–\$FFFD. Locations \$FFF6–\$FFFD contain user-defined data.

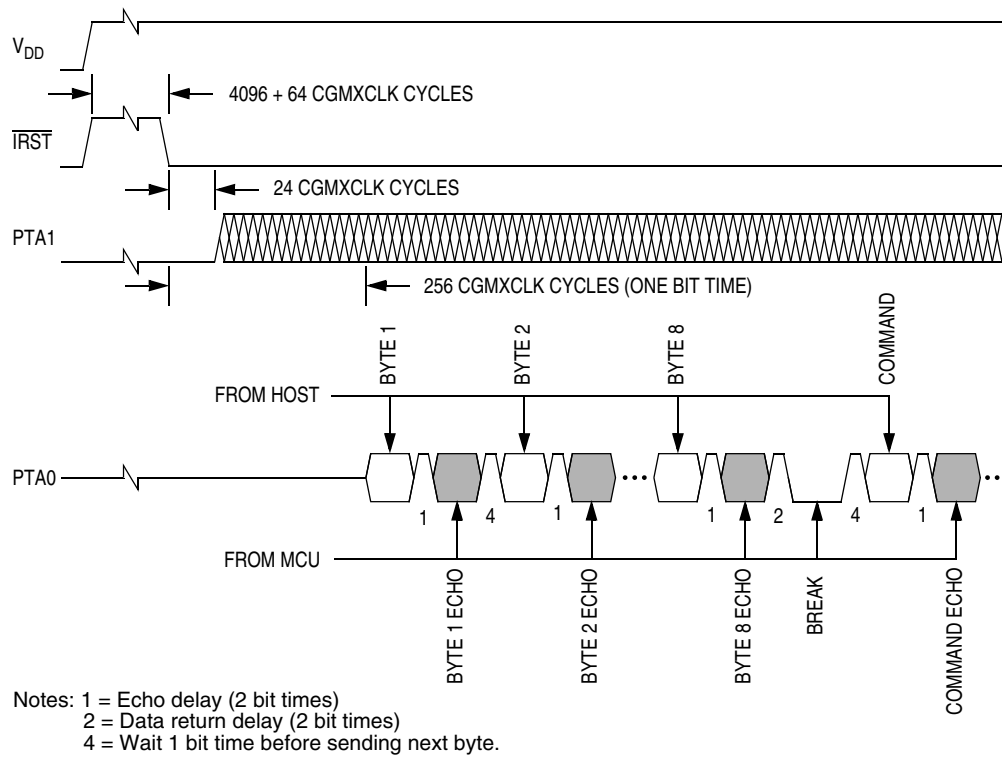

#### **NOTE**

*Do not leave locations \$FFF6–\$FFFD blank. For security reasons, program locations \$FFF6–\$FFFD even if they are not used for vectors. If FLASH is erased, the eight security byte values to be sent to the MCU are \$FF, the unprogrammed state of the FLASH.*

During monitor mode entry, a reset must be asserted. PTA1 must be held low during the reset and 24 CGMXCLK cycles after the end of the reset. Then the MCU will wait for eight security bytes on PTA0. Each byte will be echoed back to the host. See [Figure 16-15](#).

If the received bytes match those at locations \$FFF6–\$FFFD, the host bypasses the security feature and can read all FLASH locations and execute code from FLASH. Security remains bypassed until a reset occurs. After any reset, security will be locked. To bypass security again, the host must resend the eight security bytes on PTA0.

If the received bytes do not match the data at locations \$FFF6–\$FFFD, the host fails to bypass the security feature. The MCU remains in monitor mode, but reading FLASH locations returns undefined data, and trying to execute code from FLASH causes an illegal address reset.

**Figure 16-15. Monitor Mode Entry Timing**

After receiving the eight security bytes from the host, the MCU transmits a break character signalling that it is ready to receive a command.

**NOTE**

*The MCU does not transmit a break character until after the host sends the eight security bytes.*

# Chapter 17

## Electrical Specifications

### 17.1 Introduction

This section contains electrical and timing specifications.

### 17.2 Absolute Maximum Ratings

Maximum ratings are the extreme limits to which the microcontroller unit (MCU) can be exposed without permanently damaging it.

**NOTE**

*This device is not guaranteed to operate properly at the maximum ratings. Refer to 17.5 5.0-Vdc DC Electrical Characteristics, and for guaranteed operating conditions.*

Characteristic <sup>(1)</sup>	Symbol	Value	Unit
Supply voltage	$V_{DD}$	-0.3 to +6.0	V
Input voltage	$V_{In}$	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
Maximum current per pin Excluding $V_{DD}$ , $V_{SS}$ , and PTA0–PTA4	I	±15	mA
Maximum current for pins PTA0–PTA4	$I_{PTA0-IPTA4}$	±25	mA
Maximum current out of $V_{SS}$	$I_{MVSS}$	100	mA
Maximum current into $V_{DD}$	$I_{MVDD}$	100	mA
Storage temperature	$T_{STG}$	-55 to +150	°C

1. Voltages referenced to  $V_{SS}$

**NOTE**

*This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. For proper operation, it is recommended that  $V_{In}$  and  $V_{Out}$  be constrained to the range  $V_{SS} \leq (V_{In} \text{ or } V_{Out}) \leq V_{DD}$ . Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either  $V_{SS}$  or  $V_{DD}$ ).*

## 17.3 Functional Operating Range

Characteristic	Symbol	Value	Unit
Operating temperature range	$T_A$	-40 to 125	°C
Operating voltage range	$V_{DD}$	3.0 ± 10% 5.0 ± 10%	V

## 17.4 Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal resistance PDIP (16 pins) SOIC (16 pins)	$\theta_{JA}$	66 95	°C/W
I/O pin power dissipation	$P_{I/O}$	User determined	W
Power dissipation <sup>(1)</sup>	$P_D$	$P_D = (I_{DD} \times V_{DD}) + P_{I/O} =$ $K/(T_J + 273^\circ\text{C})$	W
Constant <sup>(2)</sup>	K	$P_D \times (T_A + 273^\circ\text{C})$ $+ P_D^2 \times \theta_{JA}$	W/°C
Average junction temperature	$T_J$	$T_A + (P_D \times \theta_{JA})$	°C
Maximum junction temperature	$T_{JM}$	135	°C

1. Power dissipation is a function of temperature.

2. K is a constant unique to the device. K can be determined for a known  $T_A$  and measured  $P_D$ . With this value of K,  $P_D$  and  $T_J$  can be determined for any value of  $T_A$ .

## 17.5 5.0-Vdc DC Electrical Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ <sup>(2)</sup>	Max	Unit
Output high voltage $I_{Load} = -2.0$ mA, all I/O pins $I_{Load} = -10.0$ mA, all I/O pins $I_{Load} = -15.0$ mA, PTA0–PTA4 only	$V_{OH}$	$V_{DD} - 0.4$ $V_{DD} - 1.5$ $V_{DD} - 0.8$	— — —	— — —	V
Output low voltage $I_{Load} = 1.6$ mA, all I/O pins $I_{Load} = 10.0$ mA, all I/O pins $I_{Load} = 15.0$ mA, PTA0–PTA4 only	$V_{OL}$	— — —	— — —	0.4 1.5 0.8	V
Input high voltage — all ports, $\overline{IRQ1}$	$V_{IH}$	$0.7 \times V_{DD}$	—	$V_{DD} + 0.3$	V
Input low voltage — all ports, $\overline{IRQ1}$	$V_{IL}$	$V_{SS}$	—	$0.3 \times V_{DD}$	V
$V_{DD}$ supply current Run <sup>(3), (4)</sup> Wait <sup>(4), (5)</sup> Stop, 25°C <sup>(6)</sup>	$I_{DD}$	— — —	15 2.2 0.8	25 5 1.75	mA mA $\mu$ A
I/O ports Hi-Z leakage current <sup>(7)</sup>	$I_{IL}$	-10	—	+10	$\mu$ A
Input current	$I_{In}$	-10	—	+10	$\mu$ A
Capacitance Ports (as input or output)	$C_{Out}$ $C_{In}$	— —	— —	12 8	pF
POR rearm voltage <sup>(8)</sup>	$V_{POR}$	0	—	100	mV
POR reset voltage <sup>(9)</sup>	$V_{POR}$	0	700	800	mV
POR rise time ramp rate	$R_{POR}$	0.035	—	—	V/ms
Monitor mode entry voltage	$V_{TST}$	$V_{DD} + 2.5$	—	$V_{DD} + 4.0$	V
Low-voltage inhibit reset, trip falling voltage	$V_{TRIPF}$	3.90	4.25	4.50	V
Low-voltage inhibit reset, trip rising voltage	$V_{TRIPR}$	4.20	4.35	4.60	V
Low-voltage inhibit reset/recover hysteresis	$V_{HYS}$	—	100	—	mV
Pullup resistor PTA0–PTA4, $\overline{IRQ1}$	$R_{PU}$	24	—	48	k $\Omega$

1.  $V_{DD} = 5.5$  Vdc to 4.5 Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ , unless otherwise noted

2. Typical values reflect average measurements at midpoint of voltage range, 25°C only.

3. Run (operating)  $I_{DD}$  measured using internal oscillator at its 32-MHz rate.  $V_{DD} = 5.5$  Vdc. All inputs 0.2 V from rail. No dc loads. Less than 100 pF on all outputs. All ports configured as inputs. Measured with all modules enabled.

4. All measurements taken with LVI enabled.

5. Wait  $I_{DD}$  measured using internal oscillator at its 1-MHz rate. All inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs. All ports configured as inputs.

6. Stop  $I_{DD}$  is measured with no port pin sourcing current; all modules are disabled. OSCSTOPEN option is not selected.

7. Pullups and pulldowns are disabled.

8. Maximum is highest voltage that POR is guaranteed.

9. Maximum is highest voltage that POR is possible.

## 17.6 3.0-Vdc DC Electrical Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ <sup>(2)</sup>	Max	Unit
Output high voltage $I_{Load} = -0.6$ mA, all I/O pins $I_{Load} = -4.0$ mA, all I/O pins $I_{Load} = -10$ mA, PTA0–PTA4 only	$V_{OH}$	$V_{DD} - 0.3$ $V_{DD} - 1.0$ $V_{DD} - 0.6$	— — —	— — —	V
Output low voltage $I_{Load} = 0.5$ mA, all I/O pins $I_{Load} = 6.0$ mA, all I/O pins $I_{Load} = 10$ mA, PTA0–PTA4 only	$V_{OL}$	— — —	— — —	0.3 1.0 0.6	V V V
Input high voltage — all ports, $\overline{IRQ1}$	$V_{IH}$	$0.7 \times V_{DD}$	—	$V_{DD} + 0.3$	V
Input low voltage — all ports, $\overline{IRQ1}$	$V_{IL}$	$V_{SS}$	—	$0.3 \times V_{DD}$	V
$V_{DD}$ supply current Run <sup>(3), (4)</sup> Wait <sup>(4), (5)</sup> Stop, 25°C <sup>(6)</sup>	$I_{DD}$	— — —	5 1 0.65	10 2.5 1.25	mA mA $\mu$ A
I/O ports Hi-Z leakage current <sup>(7)</sup>	$I_{IL}$	-10	—	+10	$\mu$ A
Input current	$I_{In}$	-10	—	+10	$\mu$ A
Capacitance Ports (as input or output)	$C_{Out}$ $C_{In}$	— —	— —	12 8	pF
POR rearm voltage <sup>(8)</sup>	$V_{POR}$	0	—	100	mV
POR reset voltage <sup>(9)</sup>	$V_{POR}$	0	700	800	mV
POR rise time ramp rate	$R_{POR}$	0.02	—	—	V/ms
Monitor mode entry voltage	$V_{TST}$	$V_{DD} + 2.5$	—	$V_{DD} + 4.0$	V
Low-voltage inhibit reset, trip falling voltage	$V_{TRIPF}$	2.45	2.60	2.70	V
Low-voltage inhibit reset, trip rising voltage	$V_{TRIPR}$	2.55	2.66	2.80	V
Low-voltage inhibit reset/recover hysteresis	$V_{HYS}$	—	60	—	mV
Pullup resistor PTA0–PTA4, $\overline{IRQ1}$	$R_{PU}$	24	—	48	k $\Omega$

1.  $V_{DD} = 3.3$  to  $2.7$  Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ , unless otherwise noted

2. Typical values reflect average measurements at midpoint of voltage range,  $25^\circ\text{C}$  only.

3. Run (operating)  $I_{DD}$  measured using internal oscillator at its 16-MHz rate.  $V_{DD} = 3.3$  Vdc. All inputs 0.2 V from rail. No dc loads. Less than 100 pF on all outputs. All ports configured as inputs. Measured with all modules enabled.

4. All measurements taken with LVI enabled.

5. Wait  $I_{DD}$  measured using internal oscillator at its 1 MHz rate. All inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs. All ports configured as inputs.

6. Stop  $I_{DD}$  is measured with no port pins sourcing current; all modules are disabled.

7. Pullups and pulldowns are disabled.

8. Maximum is highest voltage that POR is guaranteed.

9. Maximum is highest voltage that POR is possible.

## 17.7 Internal Oscillator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Internal oscillator base frequency <sup>(2), (3)</sup>	$f_{INTOSC}$	230.4	307.2	384	kHz
Internal oscillator tolerance	$f_{OSC\_TOL}$	-25	—	+25	%
Internal oscillator multiplier <sup>(4)</sup>	N	1	—	127	—

- $V_{DD} = 5.5$  Vdc to 2.7 Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ , unless otherwise noted
- Internal oscillator is selectable through software for a maximum frequency. Actual frequency will be multiplier (N) x base frequency.
- $f_{BUS} = (f_{INTOSC} / 4) \times N$  when internal clock source selected
- Multiplier must be chosen to limit the maximum bus frequency of 4 MHz for 2.7-V operation and 8 MHz for 4.5-V operation.

## 17.8 External Oscillator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
External clock option <sup>(2), (3)</sup> With ICG clock disabled With ICG clock enabled EXTSLOW = 1 <sup>(4)</sup> EXTSLOW = 0 <sup>(4)</sup>	$f_{EXTOSC}$	dc <sup>(5)</sup> 60 307.2 k	— — —	32 M <sup>(6)</sup> 307.2 k 32 M <sup>(6)</sup>	Hz
External crystal options <sup>(7), (8)</sup> EXTSLOW = 1 <sup>(4)</sup> EXTSLOW = 0 <sup>(4)</sup>	$f_{EXTOSC}$	30 k 1 M	— —	100 k 8 M	Hz
Crystal load capacitance <sup>(9)</sup>	$C_L$	—	—	—	pF
Crystal fixed capacitance <sup>(9)</sup>	$C_1$	—	$2 \times C_L$	—	pF
Crystal tuning capacitance <sup>(9)</sup>	$C_2$	—	$2 \times C_L$	—	pF
Feedback bias resistor <sup>(9)</sup>	$R_B$	—	10	—	M $\Omega$
Series resistor <sup>(9), (10)</sup>	$R_S$	—	—	—	M $\Omega$

- $V_{DD} = 5.5$  to 2.7 Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+125^\circ\text{C}$ , unless otherwise noted
- Setting EXTCLKEN configuration option enables OSC1 pin for external clock square-wave input.
- No more than 10% duty cycle deviation from 50%
- EXTSLOW configuration option configures external oscillator for a slow speed crystal and sets the clock monitor circuits of the ICG module to expect an external clock frequency that is higher/lower than the internal oscillator base frequency,  $f_{INTOSC}$ .
- Some modules may require a minimum frequency greater than dc for proper operation. See appropriate table for this information.
- MCU speed derates from 32 MHz at  $V_{DD} = 4.5$  Vdc to 16 MHz at  $V_{DD} = 2.7$  Vdc.
- Setting EXTCLKEN and EXTXTALEN configuration options enables OSC1 and OSC2 pins for external crystal option.
- $f_{BUS} = (f_{EXTOSC} / 4)$  when external clock source is selected.
- Consult crystal vendor data sheet, see [Figure 7-3. External Clock Generator Block Diagram](#).
- Not required for high-frequency crystals

## 17.9 Trimmed Accuracy of the Internal Clock Generator

The unadjusted frequency of the low-frequency base clock (IBASE), when the comparators in the frequency comparator indicate zero error, can vary as much as  $\pm 25\%$  due to process, temperature, and voltage. The trimming capability exists to compensate for process affects. The remaining variation in frequency is due to temperature, voltage, and change in target frequency (multiply register setting). These affects are designed to be minimal, however variation does occur. Better performance is seen at 3 V and lower settings of N.

### 17.9.1 2.7-Volt to 3.3-Volt Trimmed Internal Clock Generator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Absolute trimmed internal oscillator tolerance <sup>(2), (3)</sup> –40°C to 85°C –40°C to 125°C	$F_{\text{abs\_tol}}$	— —	2.5 4.0	5.0 5.7	%
Variation over temperature <sup>(3), (4)</sup>	$V_{\text{ar\_temp}}$	—	0.03	0.05	%/C
Variation over voltage <sup>(3), (5)</sup> 25°C –40°C to 85°C –40°C to 125°C	$V_{\text{ar\_volt}}$	— — —	0.5 0.7 0.7	2.0 2.0 2.0	%/V

1. These specifications concern long-term frequency variation. Each measurement is taken over a 1-ms period.
2. Absolute value of variation in ICG output frequency, trimmed at nominal  $V_{\text{DD}}$  and temperature, as temperature and  $V_{\text{DD}}$  are allowed to vary for a single given setting of N.
3. Specification is characterized but not tested.
4. Variation in ICG output frequency for a fixed N and voltage
5. Variation in ICG output frequency for a fixed N

### 17.9.2 4.5-Volt to 5.5-Volt Trimmed Internal Clock Generator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Absolute trimmed internal oscillator tolerance <sup>(2), (3)</sup> –40°C to 85°C –40°C to 125°C	$F_{\text{abs\_tol}}$	— —	4.0 5.0	7.0 10.0	%
Variation over temperature <sup>(3), (4)</sup>	$V_{\text{ar\_temp}}$	—	0.05	0.08	%/C
Variation over voltage <sup>(3), (5)</sup> 25°C –40°C to 85°C –40°C to 125°C	$V_{\text{ar\_volt}}$	— — —	1.0 1.0 1.0	2.0 2.0 2.0	%/V

1. These specifications concern long-term frequency variation. Each measurement is taken over a 1-ms period.
2. Absolute value of variation in ICG output frequency, trimmed at nominal  $V_{\text{DD}}$  and temperature, as temperature and  $V_{\text{DD}}$  are allowed to vary for a single given setting of N.
3. Specification is characterized but not tested.
4. Variation in ICG output frequency for a fixed N and voltage
5. Variation in ICG output frequency for a fixed N

Figure 17-1 through Figure 17-4 illustrate typical performance. The formula for this variation of frequency is  $(\text{measured-nominal})/\text{nominal}$ . Figure 17-1 shows the variation in ICG frequency for a part trimmed at nominal voltage and temperature across  $V_{DD}$  and temperature for a 3-V application with multiply register (N) set to 1. Figure 17-2 shows 5 V.

Figure 17-1. Example of Frequency Variation Across Temperature, Trimmed at Nominal 3 Volts, 25°C, and N = 1

Figure 17-2. Example of Frequency Variation Across Temperature, Trimmed at Nominal 3 Volts, 25°C, and N = 104

**Electrical Specifications**

Figure 17-3 and Figure 17-4 shows N set to 104, hex 68, which corresponds to an ICG frequency of 31.9 MHz or 7.9 MHz bus.

**Figure 17-3. Example of Frequency Variation Across Temperature, Trimmed at Nominal 5 Volts, 25°C, and N = 1**

**Figure 17-4. Example of Frequency Variation Across Temperature, Trimmed at Nominal 5 Volts, 25°C, and N = 104**

## 17.10 Analog-to-Digital Converter (ADC) Characteristics

Characteristic	Symbol	Min	Max	Unit	Notes
Supply voltage	$V_{DD}$	2.7	5.5	V	
Input voltages	$V_{ADIN}$	0	$V_{DD}$	V	
Resolution	$B_{AD}$	8	8	Bits	
Absolute accuracy <sup>(1), (2)</sup>	$A_{AD}$	-2.5	+2.5	Counts	8 bits = 256 counts
ADC clock rate	$f_{ADIC}$	500 k	1.048 M	Hz	$t_{AIC} = 1/f_{ADIC}$ , Tested only at 1 MHz
Conversion range	$R_{AD}$	$V_{SS}$	$V_{DD}$	V	
Power-up time	$t_{ADPU}$	16	—	$t_{AIC}$ cycles	
Conversion time	$t_{ADC}$	16	17	$t_{AIC}$ cycles	
Sample time	$t_{ADS}$	5	—	$t_{AIC}$ cycles	
Monotocity	$M_{AD}$	Guaranteed			
Zero input reading	$Z_{ADI}$	00	—	Hex	$V_{in} = V_{SS}$
Full-scale reading	$F_{ADI}$	—	FF	Hex	$V_{in} = V_{DD}$
Input capacitance	$C_{ADI}$	—	20	pF	Not tested

1. One count is 1/256 of  $V_{DD}$ .

2.  $V_{REFH}$  is shared with  $V_{DD}$ .  $V_{REFL}$  is shared with  $V_{SS}$ .

## 17.11 Memory Characteristics

Characteristic	Symbol	Min	Typ	Max	Unit
RAM data retention voltage	$V_{RDR}$	1.3	—	—	V
FLASH program bus clock frequency	—	1	—	—	MHz
FLASH read bus clock frequency	$f_{Read}^{(1)}$	0	—	8 M	Hz
FLASH page erase time <1 K cycles >1 K cycles	$t_{Erase}$	0.9 3.6	1 4	1.1 5.5	ms
FLASH mass erase time	$t_{MErase}$	4	—	—	ms
FLASH PGM/ERASE to HVEN setup time	$t_{NVS}$	10	—	—	$\mu$ s
FLASH high-voltage hold time	$t_{NVH}$	5	—	—	$\mu$ s
FLASH high-voltage hold time (mass erase)	$t_{NVHL}$	100	—	—	$\mu$ s
FLASH program hold time	$t_{PGS}$	5	—	—	$\mu$ s
FLASH program time	$t_{PROG}$	30	—	40	$\mu$ s
FLASH return to read time	$t_{RCV}^{(2)}$	1	—	—	$\mu$ s
FLASH cumulative program HV period	$t_{HV}^{(3)}$	—	—	4	ms
FLASH endurance <sup>(4)</sup>	—	10 k	100 k	—	Cycles
FLASH data retention time <sup>(5)</sup>	—	15	100	—	Years

1.  $f_{Read}$  is defined as the frequency range for which the FLASH memory can be read.

2.  $t_{RCV}$  is defined as the time it needs before the FLASH can be read after turning off the high voltage charge pump, by clearing HVEN to 0.

3.  $t_{HV}$  is defined as the cumulative high voltage programming time to the same row before next erase.

$t_{HV}$  must satisfy this condition:  $t_{NVS} + t_{NVH} + t_{PGS} + (t_{PROG} \times 64) \leq t_{HV}$  maximum.

4. Typical endurance was evaluated for this product family. For additional information on how Freescale defines *Typical Endurance*, please refer to Engineering Bulletin EB619.

5. Typical data retention values are based on intrinsic capability of the technology measured at high temperature and de-rated to 25°C using the Arrhenius equation. For additional information on how Freescale defines *Typical Data Retention*, please refer to Engineering Bulletin EB618.

# Chapter 18

## Ordering Information and Mechanical Specifications

### 18.1 Introduction

This section contains ordering numbers for MC68HC908KX8 and MC68HC908KX2. Refer to [Figure 18-1](#) for an example of the device numbering system.

In addition, this section gives the package dimensions for:

- 16-pin plastic dual in-line package (case number 648D)
- 16-pin small outline package (case number 751G)

### 18.2 MC Order Numbers

**Table 18-1. MC Order Numbers**

MC Order Number <sup>(1)</sup>	Operating Temperature Range
MC68HC908KX8CP MC68HC908KX8CDW	–40°C to +85°C
MC68HC908KX8VP MC68HC908KX8VDW	–40°C to +105°C
MC68HC908KX8MP MC68HC908KX8MDW	–40°C to +125°C
MC68HC908KX2CP MC68HC908KX2CDW	–40°C to +85°C
MC68HC908KX2VP MC68HC908KX2VDW	–40°C to +105°C
MC68HC908KX2MP MC68HC908KX2MDW	–40°C to +125°C

1. P = Plastic dual in-line package  
DW = Small outline package

**Figure 18-1. Device Numbering System**

### 18.3 16-Pin Plastic Dual In-Line Package (PDIP)

NOTES:

1. DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
2. CONTROLLING DIMENSION: INCH.
3. DIMENSION L TO CENTER OF LEADS WHEN FORMED PARALLEL.
4. DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION.
5. MOLD FLASH OR PROTRUSIONS SHALL NOT EXCEED 0.25 (0.010).
6. ROUNDED CORNERS OPTIONAL.

DIM	INCHES		MILLIMETERS	
	MIN	MAX	MIN	MAX
A	0.740	0.760	18.80	19.30
B	0.245	0.260	6.23	6.60
C	0.145	0.175	3.69	4.44
D	0.015	0.021	0.39	0.53
F	0.050	0.070	1.27	1.77
G	0.100 BSC		2.54 BSC	
H	0.050 BSC		1.27 BSC	
J	0.008	0.015	0.21	0.38
K	0.120	0.140	3.05	3.55

# Appendix A

## MC68HC908KX2

### A.1 Introduction

This appendix describes the differences between the MC68HC908KX8 and the MC68HC908KX2.

### A.2 Functional Description

The MC68HC908KX2 FLASH memory is an array of 2,048 bytes with an additional 36 bytes of user vectors and one byte used for block protection. See [Figure A-1](#).

**NOTE**

*An erased bit reads as a 1 and a programmed bit reads as a 0.*

The program and erase operations are facilitated through control bits in the FLASH control register (FLCR). See [2.6 FLASH Control Register](#).

The FLASH is organized internally as an 8-word by 8-bit complementary metal-oxide semiconductor (CMOS) page erase, byte (8-bit) program embedded FLASH memory. Each page consists of 64 bytes. The page erase operation erases all words within a page. A page is composed of two adjacent rows.

A security feature prevents viewing of the FLASH contents.<sup>(1)</sup>

See [2.6 FLASH Control Register](#) for a complete description of FLASH operation.

---

1. No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the FLASH difficult for unauthorized users.

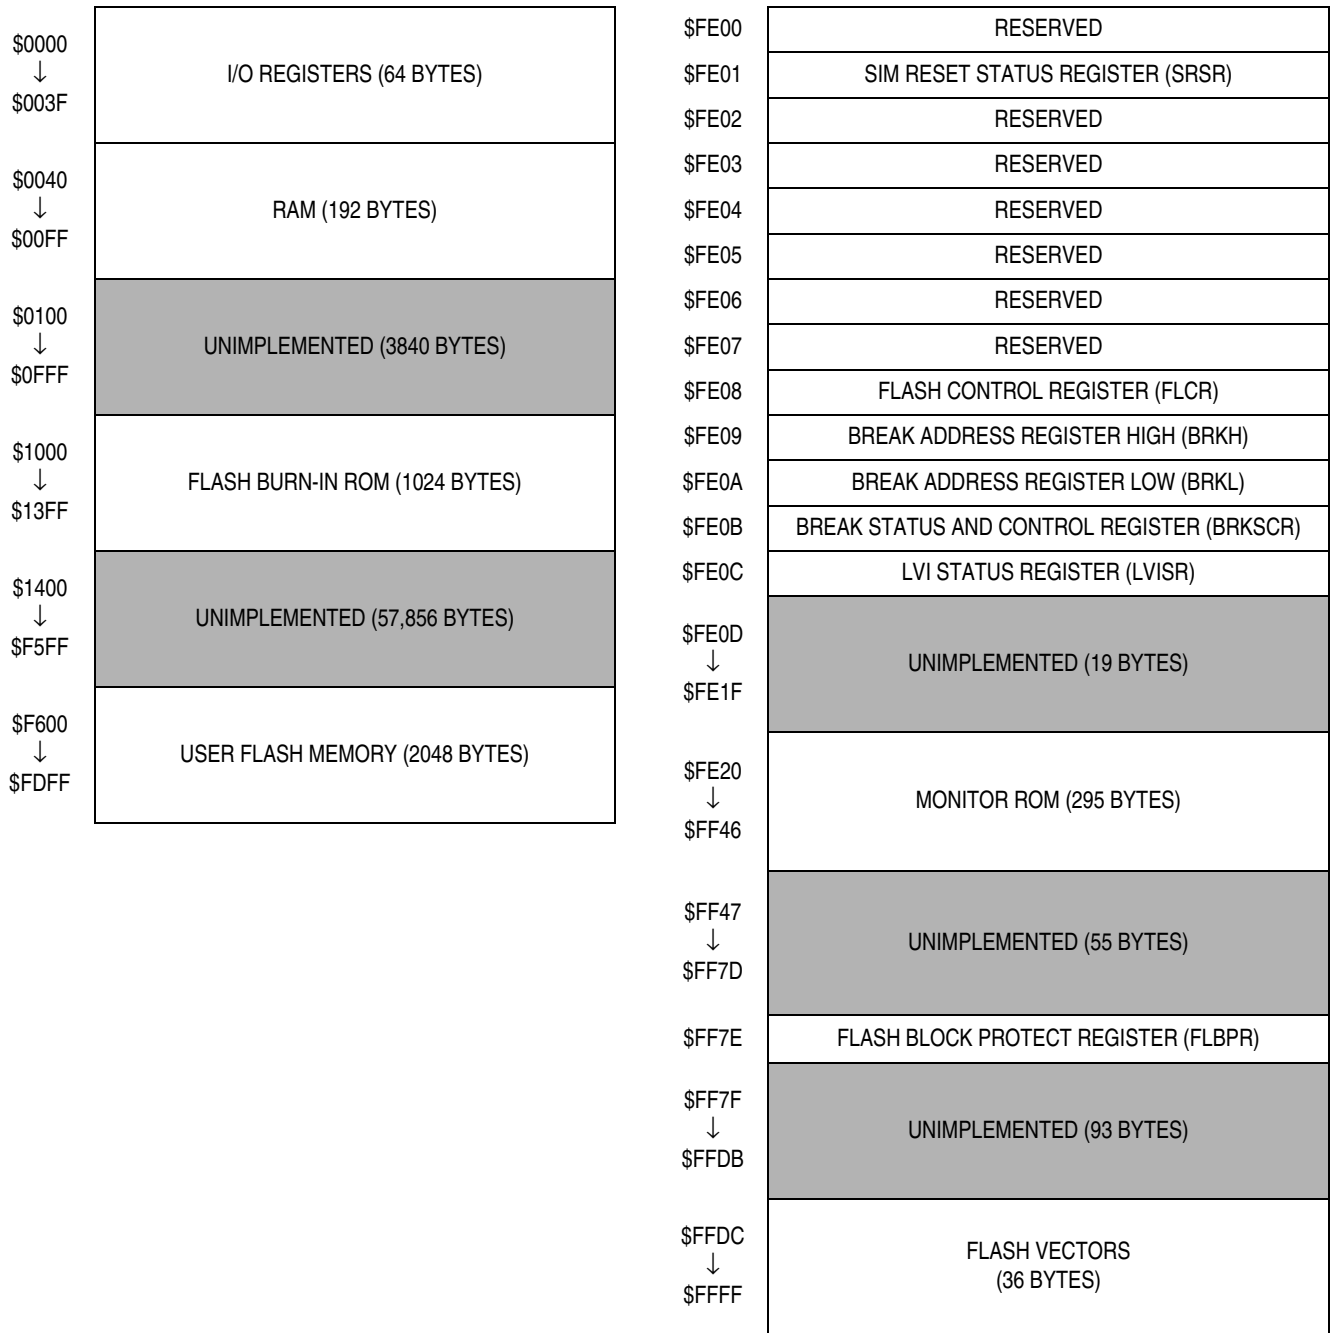

Figure A-1. MC68HC908KX2 Memory Map

# Appendix B

## MC68HC08KX8

### B.1 Introduction

This appendix describes the differences between the read-only memory (ROM) version (MC68HC08KX8) and the FLASH version (MC68HC908KX8) of the microcontroller.

Basically, the differences are:

- FLASH x ROM module changes
  - FLASH for ROM substitution
  - Partial use of FLASH-related module
- Configuration register programming
- Wider range of operating voltage

### B.2 FLASH x ROM Module Changes

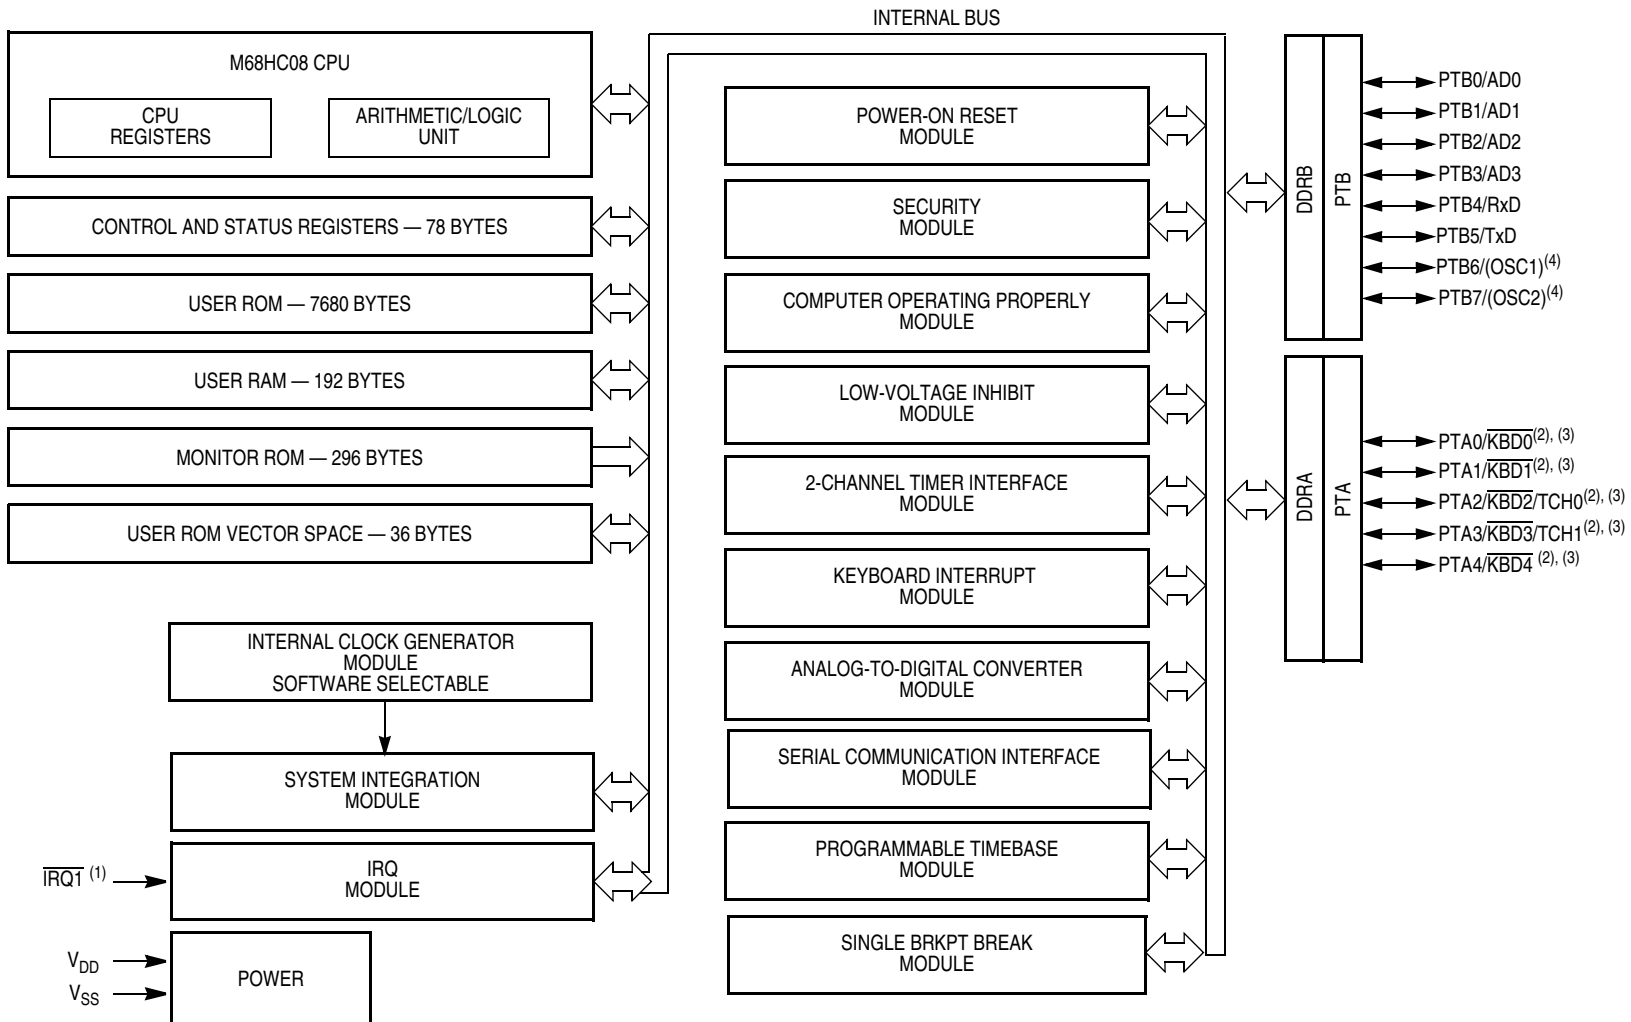

This subsection describes changes between the FLASH and ROM modules.

#### B.2.1 FLASH for ROM Substitution

FLASH memory and FLASH supporting modules are replaced by ROM memory, see [Figure B-1](#). In [Figure B-1](#), the user FLASH and user FLASH vector space are respectively substituted by user ROM and user ROM vector space.

Additionally, these modules and registers have been eliminated in the ROM version:

- FLASH burn-in ROM module — Auxiliary FLASH routine codes
- FLASH charge pump module — High-voltage for FLASH programming
- MENRST module — Helps erased FLASH parts programming, see [13.3.1.5 Forced Monitor Mode Entry Reset \(MENRST\)](#)
- SIM reset status register, bit 2 — Refers to MENRST. See [13.7.1 SIM Reset Status Register](#). MENRST has no function in the ROM version and reading this bit will return 0.
- FLASH test control register, FLTCR
- FLASH control register, FLCR
- FLASH block protect register, FLBPR

## Notes:

1. Pin contains integrated pullup resistor.
2. High-current source/sink pin
3. Pin contains software selectable pullup resistor if general function I/O pin is configured as input.
4. Pins are used for external clock source or crystal/ceramic resonator option.

Figure B-1. M68HC08KX8 MCU Block Diagram

## B.2.2 Partial Use of FLASH-Related Module

[16.3 Monitor ROM \(MON\)](#) was written having FLASH as user memory and user vector space.

MON functions are maintained for the ROM version. MON will allow execution of code in random-access memory (RAM) or ROM and provide ROM memory security<sup>(1)</sup>. The memory programming interface, though, will have no effect in ROM version.

An assumption that must be made for the ROM version is that the reset vector will always have a value different from \$0000, corresponding to the user code start address. For this reason, force entry into monitor mode, described in [16.3.1.1 Monitor Mode Entry](#) and in [16.3.1.3 Forced Monitor Mode](#), is not applicable to the ROM version. The MENRST module has been eliminated from the ROM version.

The security function described in [16.3.2 Security](#) also applies to the user ROM memory for the ROM version.

## B.3 Configuration Register Programming

Functionally, the terms MOR (mask option register) and CONFIG (configuration register) can be used interchangeably. MOR and CONFIG are equivalent since both define the same module functionality options through the registers bits. As a naming convention, though, configuration registers are named MOR for a ROM version and CONFIG for a FLASH version.

Some modules affected by the configuration register bits make reference to default values of these bits and have recommendation notes on programming them.

For specific information see:

- FLASH — [2.5 FLASH Memory \(FLASH\)](#)
- ICG — [7.6 CONFIG \(or MOR\) Register Options](#)
- LVI — [10.3 Functional Description](#)
- PORT — [11.3.1 Port B Data Register](#)
- COP — [5.4.7 COPD \(COP Disable\)](#) and [5.4.8 COPRS \(COP Rate Select\)](#)
- CONFIG — [4.2 Functional Description](#)

### NOTE

*The user must keep in mind that these notes are not entirely applicable to the MOR found in the ROM version. The MOR bits can neither assume the described CONFIG default values after reset nor can they be modified later under user code control. While the MOR is mask defined, and consequently unwritable, CONFIG can be written once after each reset.*

---

1. No security feature is absolutely secure. However, Freescale's strategy is to make reading or copying the ROM difficult for unauthorized users.

Address: \$001E

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	R	LVI2	EXTXTALEN	EXTSLOW	EXTCLKEN	0	OSCEINSTOP	SCIBDSRC
Write:								
Reset:	Unaffected by reset							
	R	= Reserved						

**Figure B-2. Mask Option Register 2 (MOR2)**

Address: \$001F

	Bit 7	6	5	4	3	2	1	Bit 0
Read:	COPRS	LVISTOP	LVIRSTD	LVIPWRD	LVI5OR3	SSREC	STOP	COPD
Write:								
Reset:	Unaffected by reset							

**Figure B-3. Mask Option Register 1 (MOR1)**

**NOTE**

*With the FLASH charge pump eliminated, MOR2 bit 2 (originally PMPREGD in CONFIG) has no effect. Reading this bit will return 0. For a complete description of other configuration bits, refer to [4.2 Functional Description](#).*

## B.4 Electrical Specifications

This subsection contains electrical and timing specifications for the MC68HC08KX8.

### B.4.1 Absolute Maximum Ratings

Maximum ratings are the extreme limits to which the microcontroller unit (MCU) can be exposed without permanently damaging it.

**NOTE**

*This device is not guaranteed to operate properly at the maximum ratings. Refer to [B.4.4 5.0-Vdc DC Electrical Characteristics](#), and for guaranteed operating conditions.*

Characteristic <sup>(1)</sup>	Symbol	Value	Unit
Supply voltage	$V_{DD}$	-0.3 to +6.0	V
Input voltage	$V_{In}$	$V_{SS} - 0.3$ to $V_{DD} + 0.3$	V
Maximum current per pin Excluding $V_{DD}$ , $V_{SS}$ , and PTA0–PTA4	I	±15	mA
Maximum current for pins PTA0–PTA4	$I_{PTA0-IPTA4}$	±25	mA
Maximum current out of $V_{SS}$	$I_{MVSS}$	100	mA
Maximum current into $V_{DD}$	$I_{MVDD}$	100	mA
Storage temperature	$T_{STG}$	-55 to +150	°C

1. Voltages referenced to  $V_{SS}$

**NOTE**

*This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. For proper operation, it is recommended that  $V_{In}$  and  $V_{Out}$  be constrained to the range  $V_{SS} \leq (V_{In} \text{ or } V_{Out}) \leq V_{DD}$ . Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (for example, either  $V_{SS}$  or  $V_{DD}$ ).*

## B.4.2 Functional Operating Range

Characteristic	Symbol	Value	Unit
Operating temperature range	$T_A$	-40 to 105	°C
Operating voltage range	$V_{DD}$	3.0 ± 10% 5.0 ± 10%	V

## B.4.3 Thermal Characteristics

Characteristic	Symbol	Value	Unit
Thermal resistance PDIP (16 pins) SOIC (16 pins)	$\theta_{JA}$	66 95	°C/W
I/O pin power dissipation	$P_{I/O}$	User determined	W
Power dissipation <sup>(1)</sup>	$P_D$	$P_D = (I_{DD} \times V_{DD}) + P_{I/O} =$ $K/(T_J + 273^\circ\text{C})$	W
Constant <sup>(2)</sup>	K	$P_D \times (T_A + 273^\circ\text{C})$ $+ P_D^2 \times \theta_{JA}$	W/°C
Average junction temperature	$T_J$	$T_A + (P_D \times \theta_{JA})$	°C
Maximum junction temperature	$T_{JM}$	125	°C

1. Power dissipation is a function of temperature.

2. K is a constant unique to the device. K can be determined for a known  $T_A$  and measured  $P_D$ . With this value of K,  $P_D$  and  $T_J$  can be determined for any value of  $T_A$ .

## B.4.4 5.0-Vdc DC Electrical Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ <sup>(2)</sup>	Max	Unit
Output high voltage I <sub>Load</sub> = -2.0 mA, all I/O pins I <sub>Load</sub> = -10.0 mA, all I/O pins I <sub>Load</sub> = -15.0 mA, PTA0-PTA4 only	V <sub>OH</sub>	V <sub>DD</sub> - 0.4 V <sub>DD</sub> - 1.5 V <sub>DD</sub> - 0.8	— — —	— — —	V
Output low voltage I <sub>Load</sub> = 1.6 mA, all I/O pins I <sub>Load</sub> = 10.0 mA, all I/O pins I <sub>Load</sub> = 15.0 mA, PTA0-PTA4 only	V <sub>OL</sub>	— — —	— — —	0.4 1.5 0.8	V
Input high voltage — all ports, $\overline{\text{IRQ1}}$	V <sub>IH</sub>	0.7 × V <sub>DD</sub>	—	V <sub>DD</sub> + 0.3	V
Input low voltage — all ports, $\overline{\text{IRQ1}}$	V <sub>IL</sub>	V <sub>SS</sub>	—	0.3 × V <sub>DD</sub>	V
V <sub>DD</sub> supply current Run <sup>(3), (4)</sup> Wait <sup>(4), (5)</sup> Stop, 25°C <sup>(4), (6)</sup>	I <sub>DD</sub>	— — —	16.6 1.9 0.8	20 5 1.75	mA mA μA
I/O ports Hi-Z leakage current <sup>(7)</sup>	I <sub>IL</sub>	-10	—	+10	μA
Input leakage current	I <sub>In</sub>	-1.0	—	+1.0	μA
Capacitance Ports (as input or output)	C <sub>Out</sub> C <sub>In</sub>	— —	— —	12 8	pF
POR rearm voltage <sup>(8)</sup>	V <sub>POR</sub>	0	—	100	mV
POR reset voltage <sup>(9)</sup>	V <sub>POR</sub>	0	700	800	mV
POR rise time ramp rate	R <sub>POR</sub>	0.035	—	—	V/ms
Monitor mode entry voltage	V <sub>TST</sub>	V <sub>DD</sub> + 2.5	—	V <sub>DD</sub> + 4.0	V
Low-voltage inhibit reset, trip falling voltage	V <sub>TRIPF</sub>	3.90	4.3	4.50	V
Low-voltage inhibit reset, trip rising voltage	V <sub>TRIPR</sub>	4.00	4.4	4.60	V
Low-voltage inhibit reset/recover hysteresis	V <sub>HYS</sub>	—	100	—	mV
Pullup resistor PTA0-PTA4, $\overline{\text{IRQ1}}$	R <sub>PU</sub>	24	—	48	kΩ

- V<sub>DD</sub> = 5.5 Vdc to 4.5 Vdc, V<sub>SS</sub> = 0 Vdc, T<sub>A</sub> = -40°C to +85°C, unless otherwise noted
- Typical values reflect average measurements at midpoint of voltage range, 25°C only.
- Run (operating) I<sub>DD</sub> measured using internal oscillator at its 32-MHz rate. V<sub>DD</sub> = 5.5 Vdc. All inputs 0.2 V from rail. No dc loads. Less than 100 pF on all outputs. All ports configured as inputs. Measured with all modules enabled.
- All measurements taken with LVI enabled.
- Wait I<sub>DD</sub> measured using internal oscillator at its 1-MHz rate. All inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs. All ports configured as inputs.
- Stop I<sub>DD</sub> is measured with no port pin sourcing current; all modules are disabled. OSCSTOPEN option is not selected.
- Pullups and pulldowns are disabled.
- Maximum is highest voltage that POR is guaranteed.
- Maximum is highest voltage that POR is possible.

## B.4.5 3.0-Vdc DC Electrical Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ <sup>(2)</sup>	Max	Unit
Output high voltage $I_{Load} = -0.6$ mA, all I/O pins $I_{Load} = -4.0$ mA, all I/O pins $I_{Load} = -10$ mA, PTA0–PTA4 only	$V_{OH}$	$V_{DD} - 0.3$ $V_{DD} - 1.0$ $V_{DD} - 0.6$	— — —	— — —	V
Output low voltage $I_{Load} = 0.5$ mA, all I/O pins $I_{Load} = 6.0$ mA, all I/O pins $I_{Load} = 10$ mA, PTA0–PTA4 only	$V_{OL}$	— — —	— — —	0.3 1.0 0.6	V V V
Input high voltage — all ports, $\overline{IRQ1}$	$V_{IH}$	$0.7 \times V_{DD}$	—	$V_{DD} + 0.3$	V
Input low voltage — all ports, $\overline{IRQ1}$	$V_{IL}$	$V_{SS}$	—	$0.3 \times V_{DD}$	V
$V_{DD}$ supply current Run <sup>(3), (4)</sup> Wait <sup>(4), (5)</sup> Stop, 25°C <sup>(4), (6)</sup>	$I_{DD}$	— — —	4.4 1 0.65	10 2.5 1.25	mA mA μA
I/O ports Hi-Z leakage current <sup>(7)</sup>	$I_{IL}$	-10	—	+10	μA
Input leakage current	$I_{In}$	-1.0	—	+1.0	μA
Capacitance Ports (as input or output)	$C_{Out}$ $C_{In}$	— —	— —	12 8	pF
POR rearm voltage <sup>(8)</sup>	$V_{POR}$	0	—	100	mV
POR reset voltage <sup>(9)</sup>	$V_{POR}$	0	700	800	mV
POR rise time ramp rate	$R_{POR}$	0.02	—	—	V/ms
Monitor mode entry voltage	$V_{TST}$	$V_{DD} + 2.5$	—	$V_{DD} + 4.0$	V
Low-voltage inhibit reset, trip falling voltage	$V_{TRIPF}$	2.4	2.60	2.70	V
Low-voltage inhibit reset, trip rising voltage	$V_{TRIPR}$	2.5	2.68	2.80	V
Low-voltage inhibit reset/recover hysteresis	$V_{HYS}$	—	80	—	mV
Pullup resistor PTA0–PTA4, $\overline{IRQ1}$	$R_{PU}$	24	—	48	kΩ

- $V_{DD} = 3.3$  to  $2.7$  Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+85^\circ\text{C}$ , unless otherwise noted
- Typical values reflect average measurements at midpoint of voltage range,  $25^\circ\text{C}$  only.
- Run (operating)  $I_{DD}$  measured using internal oscillator at its 16-MHz rate.  $V_{DD} = 3.3$  Vdc. All inputs 0.2 V from rail. No dc loads. Less than 100 pF on all outputs. All ports configured as inputs. Measured with all modules enabled.
- All measurements taken with LVI enabled.
- Wait  $I_{DD}$  measured using internal oscillator at its 1 MHz rate. All inputs 0.2 V from rail; no dc loads; less than 100 pF on all outputs. All ports configured as inputs.
- Stop  $I_{DD}$  is measured with no port pins sourcing current; all modules are disabled.
- Pullups and pulldowns are disabled.
- Maximum is highest voltage that POR is guaranteed.
- Maximum is highest voltage that POR is possible.

## B.4.6 Internal Oscillator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Internal oscillator base frequency <sup>(2), (3)</sup>	$f_{INTOSC}$	230.4	320	384	kHz
Internal oscillator tolerance	$f_{OSC\_TOL}$	-25	—	+25	%
Internal oscillator multiplier <sup>(4)</sup>	N	1	—	127	—

- $V_{DD} = 5.5$  Vdc to 2.7 Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+85^\circ\text{C}$ , unless otherwise noted
- Internal oscillator is selectable through software for a maximum frequency. Actual frequency will be multiplier (N) x base frequency.
- $f_{BUS} = (f_{INTOSC} / 4) \times N$  when internal clock source selected
- Multiplier must be chosen to limit the maximum bus frequency of 4 MHz for 2.7-V operation and 8 MHz for 4.5-V operation.

## B.4.7 External Oscillator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
External clock option <sup>(2), (3)</sup> With ICG clock disabled With ICG clock enabled EXTSLOW = 1 <sup>(4)</sup> EXTSLOW = 0 <sup>(4)</sup>	$f_{EXTOSC}$	dc <sup>(5)</sup> 60 307.2 k	— — —	32 M <sup>(6)</sup> 307.2 k 32 M <sup>(6)</sup>	Hz
External crystal options <sup>(7), (8)</sup> EXTSLOW = 1 <sup>(4)</sup> EXTSLOW = 0 <sup>(4)</sup>	$f_{EXTOSC}$	30 k 1 M	— —	100 k 8 M	Hz
Crystal load capacitance <sup>(9)</sup>	$C_L$	—	—	—	pF
Crystal fixed capacitance <sup>(9)</sup>	$C_1$	—	$2 \times C_L$	—	pF
Crystal tuning capacitance <sup>(9)</sup>	$C_2$	—	$2 \times C_L$	—	pF
Feedback bias resistor <sup>(9)</sup>	$R_B$	—	10	—	M $\Omega$
Series resistor <sup>(9), (10)</sup>	$R_S$	—	—	—	M $\Omega$

- $V_{DD} = 5.5$  to 2.7 Vdc,  $V_{SS} = 0$  Vdc,  $T_A = -40^\circ\text{C}$  to  $+85^\circ\text{C}$ , unless otherwise noted
- Setting EXTCLKEN configuration option enables OSC1 pin for external clock square-wave input.
- No more than 10% duty cycle deviation from 50%
- EXTSLOW configuration option configures external oscillator for a slow speed crystal and sets the clock monitor circuits of the ICG module to expect an external clock frequency that is higher/lower than the internal oscillator base frequency,  $f_{INTOSC}$ .
- Some modules may require a minimum frequency greater than dc for proper operation. See appropriate table for this information.
- MCU speed derates from 32 MHz at  $V_{DD} = 4.5$  Vdc to 16 MHz at  $V_{DD} = 2.7$  Vdc.
- Setting EXTCLKEN and EXTXTALEN configuration options enables OSC1 and OSC2 pins for external crystal option.
- $f_{BUS} = (f_{EXTOSC} / 4)$  when external clock source is selected.
- Consult crystal vendor data sheet, see [Figure 7-3. External Clock Generator Block Diagram](#).
- Not required for high-frequency crystals

## B.4.8 Trimmed Accuracy of the Internal Clock Generator

The unadjusted frequency of the low-frequency base clock (IBASE), when the comparators in the frequency comparator indicate zero error, can vary as much as  $\pm 25\%$  due to process, temperature, and voltage. The trimming capability exists to compensate for process affects. The remaining variation in frequency is due to temperature, voltage, and change in target frequency (multiply register setting). These affects are designed to be minimal, however variation does occur. Better performance is seen at 3 V and lower settings of N.

### B.4.8.1 2.7-Volt to 3.3-Volt Trimmed Internal Clock Generator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Absolute trimmed internal oscillator tolerance <sup>(2), (3)</sup> –40°C to 85°C	$F_{abs\_tol}$	—	1.5	5.0	%
Variation over temperature <sup>(3), (4)</sup>	$V_{ar\_temp}$	—	0.03	0.05	%/C
Variation over voltage <sup>(3), (5)</sup> 25°C –40°C to 85°C	$V_{ar\_volt}$	— —	0.5 0.7	2.0 2.0	%/V

1. These specifications concern long-term frequency variation. Each measurement is taken over a 1-ms period.
2. Absolute value of variation in ICG output frequency, trimmed at nominal  $V_{DD}$  and temperature, as temperature and  $V_{DD}$  are allowed to vary for a single given setting of N.
3. Specification is characterized but not tested.
4. Variation in ICG output frequency for a fixed N and voltage
5. Variation in ICG output frequency for a fixed N

### B.4.8.2 4.5-Volt to 5.5-Volt Trimmed Internal Clock Generator Characteristics

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Absolute trimmed internal oscillator tolerance <sup>(2), (3)</sup> –40°C to 85°C	$F_{abs\_tol}$	—	4.0	7.0	%
Variation over temperature <sup>(3), (4)</sup>	$V_{ar\_temp}$	—	0.05	0.08	%/C
Variation over voltage <sup>(3), (5)</sup> 25°C –40°C to 85°C	$V_{ar\_volt}$	— —	1.0 1.0	2.0 2.0	%/V

1. These specifications concern long-term frequency variation. Each measurement is taken over a 1-ms period.
2. Absolute value of variation in ICG output frequency, trimmed at nominal  $V_{DD}$  and temperature, as temperature and  $V_{DD}$  are allowed to vary for a single given setting of N.
3. Specification is characterized but not tested.
4. Variation in ICG output frequency for a fixed N and voltage
5. Variation in ICG output frequency for a fixed N

### B.4.9 Analog-to-Digital Converter (ADC) Characteristics

Characteristic	Symbol	Min	Max	Unit	Notes
Supply voltage	$V_{DD}$	2.7	5.5	V	
Input voltages	$V_{ADIN}$	0	$V_{DD}$	V	
Resolution	$B_{AD}$	8	8	Bits	
Absolute accuracy <sup>(1), (2)</sup>	$A_{AD}$	-2.5	+2.5	Counts	8 bits = 256 counts
ADC clock rate	$f_{ADIC}$	500 k	1.048 M	Hz	$t_{AIC} = 1/f_{ADIC}$ , Tested only at 1 MHz
Conversion range	$R_{AD}$	$V_{SS}$	$V_{DD}$	V	
Power-up time	$t_{ADPU}$	16	—	$t_{AIC}$ cycles	
Conversion time	$t_{ADC}$	16	17	$t_{AIC}$ cycles	
Sample time	$t_{ADS}$	5	—	$t_{AIC}$ cycles	
Monotocity	$M_{AD}$	Guaranteed			
Zero input reading	$Z_{ADI}$	00	—	Hex	$V_{In} = V_{SS}$
Full-scale reading	$F_{ADI}$	—	FF	Hex	$V_{In} = V_{DD}$
Input capacitance	$C_{ADI}$	—	20	pF	Not tested

1. One count is 1/256 of  $V_{DD}$ .

2.  $V_{REFH}$  is shared with  $V_{DD}$ .  $V_{REFL}$  is shared with  $V_{SS}$ .

### B.4.10 Memory Characteristics

Characteristic	Symbol	Min	Max	Units
RAM data retention voltage <sup>(1)</sup>	$V_{RDR}$	1.3	—	V

1. Specification is characterized but not tested.
