

170 mA 13 V, high efficiency boost converter + LDO

Datasheet - production data

Description

The STOD1317B is a fixed frequency, high efficiency, boost DC-DC converter with cascaded LDO able to provide output voltages ranging from 6 V to 13 V starting with an input voltage from 2.6 V to 4.8 V. The device is designed to supply loads that are very sensitive to output ripple such as AMOLED display panels. A dedicated LDO is able to suppress any ripple and noise coming out from the DC-DC converter. The LDO works with a constant drop in order to maintain high efficiency in the whole operating range. The low R_{DSon} N-channel and P-channel MOSFET switches are integrated and contribute to achieving high efficiency. The true-shutdown feature allows physical disconnection of the battery from the load when the device is in shutdown mode. The control technique is able to maintain efficiency higher than 85% at light loads and higher than 80% at full load. The device includes soft-start control, inrush current limiter, thermal shutdown and inductor peak current limit. The STOD1317B is packaged in DFN12L (3 x 3 x 0.8 mm) height.

Features

- Operating input voltage range from 2.6 V to 4.8 V
- $\pm 1\%$ output voltage tolerance
- Low output ripple
- True-shutdown
- Short-circuit protection
- Digital low power function
- Very high efficiency at light load thanks to pulse skipping operation
- Very fast line and load transients
- 1.2 MHz switching frequency
- 1 μ A max. quiescent current
- DFN12L (3 x 3 x 0.8 mm)

Applications

- Single rail AMOLED display
- Cellular phones
- Battery powered equipment

6 Detailed description

The STOD1317B is a high efficiency DC-DC converter which integrates a step-up and LDO power stage suitable for supplying AMOLED panels. Thanks to the high level of integration it needs only 6 external components to operate and it achieves very high efficiency using a synchronous rectification technique.

The controller uses an average current mode technique in order to obtain good stability and precise voltage regulation in all possible conditions of input voltage, output voltage and output current. In addition, the peak inductor current is monitored in order to avoid saturation of the coils.

The STOD1317B implements a power saving technique in order to maintain high efficiency at very light load and it switches to PWM operation as the load increases in order to guarantee the best dynamic performances and low noise operation.

In order to guarantee very low ripple on the output voltage, the step-up output is filtered by the LDO. There are two control loops; the LDO control loop regulates V_{OUT} in order to provide the right voltage to the output, while the boost control loop is internally set to provide and output voltage 380 mV higher than V_{OUT} in order to maintain the LDO in regulation at the minimum possible drop.

The STOD1317B avoids battery leakage thanks to the true-shutdown feature and it is self protected from overtemperature and short-circuit on the V_{OUT} pin. Undervoltage lockout and soft-start guarantee proper operation during startup.

6.1 BOOST multiple mode of operation

The boost DC-DC operates in three different modes: pulse skipping (PS), discontinuous conduction mode (DCM) and continuous conduction mode (CCM). It switches automatically between the three modes according to input voltage, output current and output voltage conditions.

6.1.1 Pulse skipping operation

The STOD1317B works in pulse skipping mode when the load current is below some tens of mA. The load current level at which this way of operation occurs depends on the input and output voltage.

6.1.2 Discontinuous conduction mode

When the load increases above some tens of mA, the STOD1317B enters DCM operation.

In order to obtain this type of operation the controller must avoid the inductor current going negative. The discontinuous mode detector (DMD) block senses the voltage across the synchronous rectifier and turns off the switch when the voltage crosses a defined threshold which, in turn, represents a certain current in the inductor. This current can vary according to the slope of the inductor current which depends on input voltage, inductance value, and output voltage.

6.1.3 Continuous conduction mode

At medium/high output loads the STOD1317B enters full CCM at constant switching frequency mode.

6.2 Enable pin

The device operates when the EN pin is set high. If the EN pin is set low, the device stops switching, all the internal blocks are turned off. In this condition the current drawn from V_{IN} is below 1 μA in the whole temperature range. In addition, the internal switches are in OFF state so the load is electrically disconnected from the input, this avoids unwanted current leakage from the input to the load.

6.3 Soft-start and inrush current limiting

After the EN pin is pulled high, or after a suitable voltage is applied to V_{IN} and EN, the device initiates the startup phase.

As a first step, the C_{MID} capacitor is charged, the P1 switch implements a current limiting technique in order to keep the charge current below 400 mA. This avoids battery overloading during startup.

After V_{MID} reaches the V_{IN} voltage level, the P1 switch is fully turned on and the soft-start procedure for the step-up is started. V_{OUT} starts to softly increase until it reaches the regulation value.

6.4 Undervoltage lockout

The undervoltage lockout function avoids improper operation of the STOD1317B when the input voltage is not high enough. When the input voltage is below the UVLO threshold the device is in shutdown mode. The hysteresis of 100 mV avoids unstable operation when the input voltage is close to the UVLO threshold.

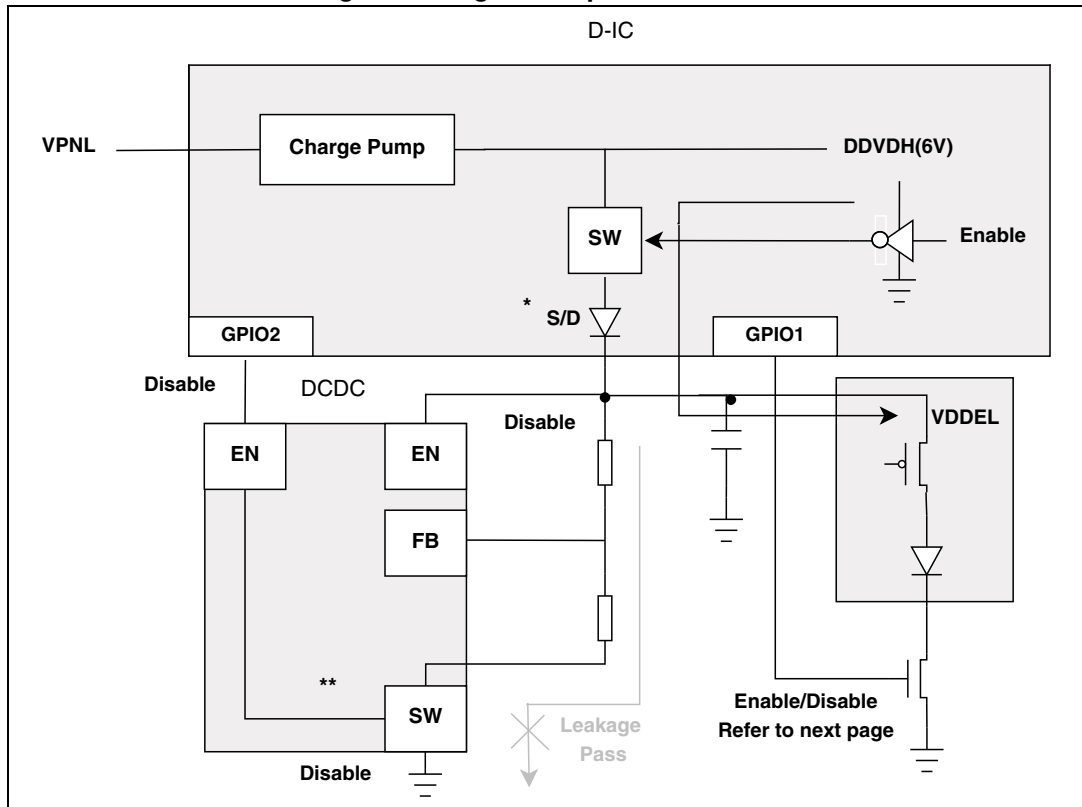

6.5 Overtemperature protection

An internal temperature sensor continuously monitors the IC junction temperature. If the IC temperature exceeds 150 $^{\circ}\text{C}$, typical, the device stops operating. As soon as the temperature falls below 135 $^{\circ}\text{C}$, typical, normal operation is restored.

6.6 Digital low power function

The digital low power (DLP) function allows physical disconnection of the load from the device.

Figure 11. Digital low power function

Operation

- (*) When the power IC is disabled, in order to disconnect leakage current through the feedback node, the S/W function is active.
- (**) A new EN transition from low to high and/or device power-up turn off the DLP function and allow IC to work under typical conditions.

7 Application information

7.1 External passive components

7.1.1 Inductor selection

The inductor is the key passive component for switching converters.

For the step-up converter an inductance between 3.3 μH and 6.8 μH is recommended.

It is very important to select the right inductor according to the maximum current the inductor can handle in order to avoid saturation. The peak current for the step-up can be calculated as:

Equation 1

$$I_{\text{PEAK BOOST}} = \frac{V_{\text{MID}} \times I_{\text{OUT}}}{\eta \times V_{\text{INMIN}}} + \frac{V_{\text{INMIN}} \times (V_{\text{MID}} - V_{\text{INMIN}})}{2 \times V_{\text{MID}} \times f_{\text{s}} \times L}$$

where

V_{MID} : step-up output voltage, it is fixed internally to $V_{\text{OUT}} + 0.38 \text{ V}$;

I_{OUT} : output current;

V_{IN} : input voltage of the STOD1317B;

f_{s} : switching frequency. Use the minimum value of 1 MHz for worst case;

η : efficiency of the step-up converter (0.80 at maximum load).

7.1.2 Input and output capacitor selection

It is recommended to use ceramic capacitors with low ESR as input and output capacitors in order to filter any disturbance present in the input line and to obtain stable operation of the step-up converter and LDO. A minimum real capacitance value of 3 μF must be guaranteed for C_{MID} and C_{OUT} in all conditions.

7.2 Recommended PCB layout

The STOD1317B is a high frequency power switching device so it requires a proper PCB layout in order to obtain the necessary stability and optimize line/load regulation and output voltage ripple.

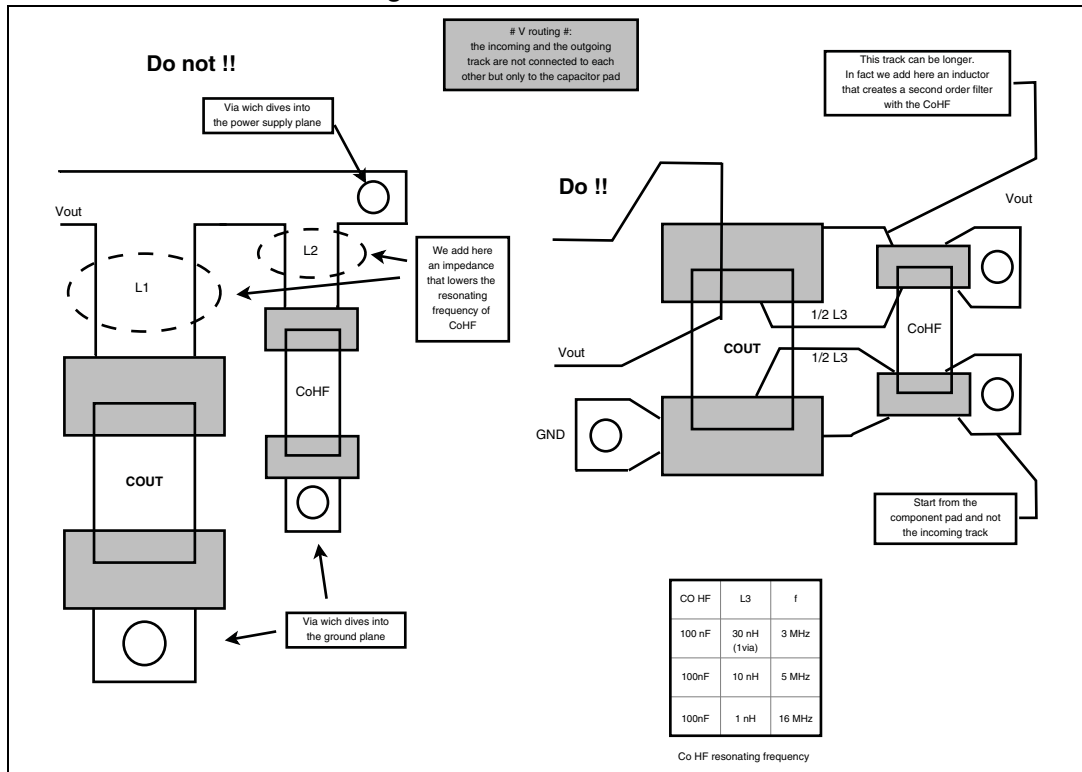

The input capacitor must be as close as possible to the V_{IN} pin.

In order to minimize the ground noise, a common ground node for power ground (PGND) and a different one for analog ground (GND) must be used. The exposed pad is connected to PGND through vias.

Grounding is fundamental to the operation of DC-DC converters; run separate ground paths for critical parts of the circuit (GND and Power GND), each connected back to a single ground point.

Separate ground lines prevent the current and noise of one component from interfering with other components. If using a ground plane, utilize "split" plane techniques to give effective grounding. Use multiple vias to decrease the trace impedance to ground.

Figure 12. Ground schematic

Such isolation is necessary to prevent high-level switching currents from returning to the battery, or other power supply, through the same ground-return path as the analog signals.

If that happens, the ground path of those sensitive signals is disturbed; the high-level switching currents flowing through the ground's resistance and inductance cause the voltage along the return path to vary.

In addition to the grounding scheme, proper placement of the regulator's components is important.

Beginning a new layout, for the reasons above, it is necessary to firstly place the capacitors C_{IN} , C_{OUT} and C_{MID} as close as possible to the related device pins.

After that, it is possible to place the inductors and the Power GND routing. Next, we can trace the GND connected through vias to the PGND near to one of the main filter capacitors.

The LDO needs a quiet ground signal in order to operate properly.

It is important to pay close attention to the routing of traces from capacitor terminals in a DC-DC converter circuit.

Large-valued low-ESR capacitors are expensive, and bad routings can cancel their performance.

A good routing, on the other hand, can lower the output noise.

Ripple is directly related to the inductor value, the capacitor ESR, the switching frequency, and so forth, but HF noise (spikes) depends on parasitic elements and the switching action. In a bad routing, parasitic inductance associated with trace lengths causes problems: In [Figure 12](#), L1 brings about an increase in noise, and L2 limits the attenuation of an added HF capacitor. The solution is to bring the input trace in on one side of the capacitor pad, and the output trace out on the other side of the pad.
