FAN7389 3-Phase Half-Bridge Gate-Drive IC

Features

SEMICONDUCTOR

- Floating Channel for Bootstrap Operation to +600 V
- Typically 350 mA/650 mA Sourcing/Sinking Current Driving Capability for All Channels
- Extended Allowable Negative V_S Swing to -9.8 V for Signal Propagation at V_{DD}=V_{BS}=15 V
- Output In-Phase with Input Signal
- Over-Current Shutdown Turns off All Six Drivers
- Matched Propagation Delay for All Channels
- 3.3 V and 5.0 V Input Logic Compatible
- Adjustable Fault-Clear Timing
- Built-in Advanced Input Filter
- Built-in Shoot-Through Prevention Logic
- Built-in Soft Turn-Off Function
- Common-Mode dv/dt Noise Canceling Circuit
- Built-in UVLO Functions for All Channels

Applications

- 3-Phase Motor Inverter Driver
- Air Conditioners
- Washing Machines
- General-Purpose Three-Phase Inverters

Description

The FAN7389 is a monolithic three-phase half-bridge gate-drive IC designed for high-voltage, high-speed driving MOSFETs and IGBTs operating up to +600 V.

Fairchild's high-voltage process and common-mode noise canceling technique provide stable operation of high-side drivers under high-dv/dt noise circumstances.

An advanced level-shift circuit allows high-side gate driver operation up to V_{S} = -9.8 V (typical) for V_{BS} =15 V.

The protection functions include under-voltage lockout and inverter over-current trip with an automatic faultclear function.

Over-current protection that terminates all six outputs can be derived from an external current-sense resistor. An open-drain fault signal is provided to indicate that an over-current or under-voltage shutdown has occurred.

The UVLO circuits prevent malfunction when V_{DD} and V_{BS} are lower than the specified threshold voltage.

Output drivers typically source and sink 350 mA and 650 mA, respectively; which is suitable for three-phase half-bridge applications in motor drive systems.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only. $T_A=25^{\circ}C$, unless otherwise specified.

Notes:

6. These parameters are guaranteed by design.

7. These parameters are referenced to specified C_{RCIN} (=2 nF), and proportional to value of C_{RCIN} as shown in Figure 43. It is strongly recommended that the capacitor on R_{CIN} pin should be less than 5 nF.

8. The minimum width of the input pulse should exceed 500 ns to ensure the filtering time of the input filter is exceeded.

9. PM is defined as PW_{IN}-PW_{OUT}.

Applications Information

1. Dead Time

Dead time is automatically inserted whenever the dead time of the external two input signals (between HINx and LINx signals) is shorter than internal fixed dead times (DT1 and DT2). Otherwise, external dead times larger than internal dead times are not modified by the gate driver and internal dead-time waveform definition is shown in Figure 37.

Figure 37.Internal Dead-Time Definitions

2. Protection Function

2.1 Fault Out (FO) and Under-Voltage Lockout

The high- and iow-side drivers include under-voltage lockout (UVLO) protection circuitry that monitors the supply voltage for V_{DD} and V_{BS} independently. It can be designed to prevent malfunction when V_{DD} and V_{BS} are lower than the specified threshold voltage. Also, the UVLO hysteresis prevents chattering during power-supply transitions. Moreover, the fault signal (FO) goes to LOW state to operate reliably during power-on events, when the power supply (V_{DD}) is below the under-voltage lockout high threshold voltage for the circuit (during $t_1 \sim t_2$). The UVLO circuit is not otherwise activated; shown Figure 38.

2.2 Shoot-Through Protection

The shoot-through protection circuitry prevents both high- and low-side switches from conducting at the same time, as shown Figure 39.

Example B Figure 39.Shoot-Through Protection

2.3 Enable Input

When the EN pin is in HIGH state, the gate driver operates normally. When a condition occurs that should shut down the gate driver, the EN pin should be LOW. The enable circuitry has an input filter; the minimum input duration is specified by t_{FLTIN} (typically 250 ns).

2.4 Fault-Out (FO) and Over-Current Protection

FAN7389 provides an integrated fault output (\overline{FO}) and an adjustable fault-clear timer (t_{FLTCLR}). There are two situations that cause the gate driver to report a fault via the FO pin. The first is an under-voltage condition of low-side gate driver supply voltage (V_{DD}) and the second is when the current-sense pin (CS) recognizes a fault. Once the fault condition occurs, the FO pin is internally pulled to COM, the fault-clear timer is activated, and all outputs (HO1,2,3 and LO1,2,3) of the gate driver are turned off. The fault output stays LOW until the fault condition has been removed and the faultclear timer expires. Once the fault-clear timer expires, the voltage on the FO pin returns to pull-up voltage.

The fault-clear time (t_{FLTCLR}) is determined by an internal current source (I_{RCIN} =5 μ A) and an external C_{RCIN} at the RCIN pin, as shown in this equation:

$$t_{FLTCLR} = \frac{C_{RCIN} \times V_{RCIN,TH}}{I_{RCIN}} [s]$$
(1)

The R_{DSRCIN} of the MOSFET is a characteristic discharge curve with respect to the external capacitor C_{RCIN} . The time constant is defined by the external capacitor C_{RCIN} and the R_{DSRCIN} of the MOSFET.

The output of current-sense comparator (CS_COMP) passes a noise filter, which inhibits an over-current shutdown caused by parasitic voltage spikes of V_{CS} .

This corresponds to a voltage level at the comparator of $V_{CSTH+} - V_{CSHYS}$ = 500 mV - 60 mV =440 mV, where V_{CSHYS} =60 mV is the hysteresis of the current comparator (CS_COMP) as shown in Figure 41.

Figure 41.Over-Current Protection

Figure 42 shows the waveform definitions of RCIN, FO and the low-side driver, which uses a soft turn-off method when an under-voltage condition of the low-side gate driver supply voltage (V_{DD}) or the current-sense pin (CS) recognizes a fault. Once a fault condition occurs, the FO pin is internally pulled to COM and all outputs (HO1,2,3 and LO1,2,3) of the gate driver are turned off. Low-side outputs decline linearly by the internal sink current source (I_{SOFT} =40 mA) for soft turn-off, as shown in Figure 42.

Figure 42. RCIN and Fault-Clear Waveform Definition

2.5 Recommended R_{CIN}

Figure 43 shows timing of t_{CSOFF} and t_{CSFO} versus C_{RCIN}.

It is strongly recommended that the capacitor on R_{CIN} pin should be less than 5 nF in order to properly protect power devices in over-current situations.

Figure 43. Timing of t_{CSOFF} and t_{CSFO} vs. C_{RCIN}

3. Noise Filter

3.1 Input Noise Filter

Figure 44 shows the input noise filter method, which has symmetry duration between the input signal (t_{INPUT}) and the output signal (t_{OUTPUT}) and helps to reject noise spikes and short pulses. This input filter is applied to the HINx, LINx, and EN inputs. The upper pair of waveforms (Example A) shows an input signal duration (t_{INPUT}) much longer than input filter time (t_{FLTIN}); it is approximately the same duration between the input signal time (t_{INPUT}) and the output signal time (t_{OUTPUT}). The lower pair of waveforms (Example B) shows an input signal time (t_{FLTIN}); it is approximately the same duration between the input signal time (t_{FLTIN}); it is approximately the same duration between input signal time (t_{INPUT}) slightly longer than input filter time (t_{FLTIN}); it is approximately the same duration between input signal time (t_{INPUT}) and the output signal time (t_{INPUT}).

Figure 44.Input Noise Filter Definition

3.2. Short-Pulsed Input Noise Rejection Method

The input filter circuitry provides protection against short-pulsed input signals (HINx, LINx, and EN) on the input signal lines by applied noise signal.

If the input signal duration is less than input filter time $(t_{\mathsf{FLTIN}}),$ the output does not change states.

Example A and B of the Figure 45 show the input and output waveforms with short-pulsed noise spikes with a duration less than input filter time; the output does not change states.

Figure 45. Noise Rejecting Input Filter Definition

Figure 46 shows the characteristics of the input filters while receiving narrow ON and OFF pulses. If input signal pulse duration, PW_{IN} , is less than input filter time, t_{FLTIN} ; the output pulse, PW_{OUT} , is zero. The input signal is rejected by input filter. Once the input signal pulse duration, PW_{IN} , exceeds input filter time, t_{FLTIN} , the output pulse durations, PW_{OUT} , matches the input pulse durations, PW_{IN} . FAN7389 input filter time, t_{FLTIN} , is about 250 ns for the high- and low-side outputs.
