OCTAL BUS EXCHANGE SWITCH

IDT74FST3383
IDT74FST32383
PRELIMINARY

FEATURES:

- Bus Switches provide zero delay paths
- Extended commercial range of -40°C to $+85^{\circ}\text{C}$
- Low switch on-resistance:
 FST3xxx – 5Ω
 FST32xxx – 28Ω
- TTL-compatible input and output levels
- ESD > 2000V per MIL-STD-883, Method 3015;
 > 200V using machine model (C = 200pF, R = 0)
- Available in QSOP, TSSOP, SOIC and PDIP

DESCRIPTION:

The FST3383/32383 belong to IDT's family of Bus Switches. Bus switch devices perform the function of connecting or isolating two ports without providing any inherent current sink or source capability. Thus they generate little or no noise of

their own while providing a low resistance path for an external driver. These devices connect input and output ports through an n-channel FET. When the gate-to-source junction of this FET is adequately forward-biased the device conducts and the resistance between input and output ports is small. Without adequate bias on the gate-to-source junction of the FET, the FET is turned off, therefore with no Vcc applied, the device has hot insertion capability.

The low on-resistance and simplicity of the connection between input and output ports reduces the delay in this path to close to zero.

The FST32383 integrates terminating resistors in the device, thus eliminating the need for external 25Ω series resistors.

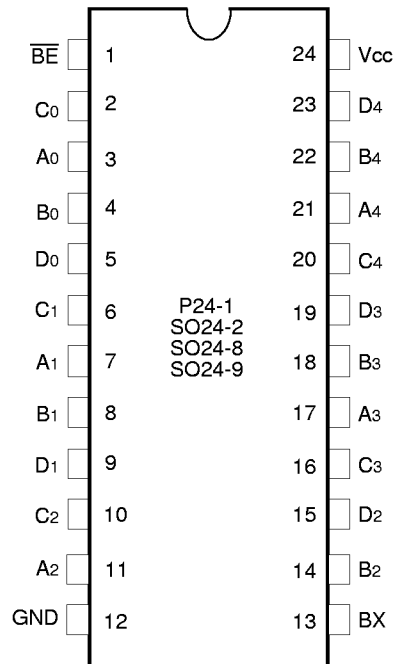

The FST3383 and FST32383 each provide four 5-bit TTL-compatible ports that support 2 way bus exchange. The BX pin controls the bus exchange and the $\overline{\text{BE}}$ pin serves as the enable pin.

- Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.
- V_{CC}, Control and Switch terminals.

NOTES:

- For conditions shown as Max. or Min., use appropriate value specified under Electrical Characteristics for the applicable device type.
- Typical values are at V_{CC} = 5.0V, +25°C ambient.
- Not more than one output should be tested at one time. Duration of the test should not exceed one second.
- Measured by voltage drop between ports at indicated current through the switch.

- For conditions shown as Max. or Min., use appropriate value specified under Electrical Characteristics for the applicable device type.
- Typical values are at $V_{CC} = 5.0V$, $+25^\circ\text{C}$ ambient.
- Per TTL driven input ($V_{IN} = 3.4V$). All other inputs at V_{CC} or GND .
- This parameter is not directly testable, but is derived for use in Total Power Supply Calculations.
- Values for these conditions are examples of the I_{CC} formula. These limits are guaranteed but not tested.
- $I_C = I_{\text{QUIESCENT}} + I_{\text{INPUTS}} + I_{\text{DYNAMIC}}$
 $I_C = I_{CC} + \Delta I_{CC} \text{DHNT} + I_{CCD} (f_i N)$
 $I_{CC} = \text{Quiescent Current}$
 $\Delta I_{CC} = \text{Power Supply Current for a TTL High Input } (V_{IN} = 3.4V)$
 $\text{DH} = \text{Duty Cycle for TTL Inputs High}$
 $\text{NT} = \text{Number of TTL Inputs at DH}$
 $I_{CCD} = \text{Dynamic Current Caused by an Input Transition Pair (HLH or LHL)}$

NOTES:

3258 tbl 07

- See test circuit and waveforms.
- Minimum limits guaranteed but not tested.
- This parameter is guaranteed by design but not tested.
- The bus switch contributes no propagation delay other than the RC delay of the on resistance of the switch and the load capacitance. The time constant for the switch alone is of the order of 0.25 ns for 50 pF load. Since this time is constant and much smaller than the rise/fall times of typical driving signals, it adds very little propagation delay to the system. Propagation delay of the bus switch when used in a system is determined by the driving circuit on the driving side of the switch and its interaction with the load on the driven side.
- Measured at switch turn off, load = 50 pF in parallel with 10 M Ω scope probe, $V_{IN} = 0.0$ volts.
- Measured at switch turn off through bus multiplexer, (e.g. - A to C => A to D), load = 50 pF in parallel with 10 M Ω scope probe, V_{IN} at A = 0.0 volts. Charge injection is reduced because the injection from the turn off of the A to C switch is compensated by the turn on of the B to C switch.
- Characterized parameter. Not 100% tested.
