350-W Interleaved PFC Pre-Regulator

1 Introduction

The evaluation module is a 350-W, two phase interleaved power factor corrected pre-regulator. This evaluation module has a 380-V, 350-W, dc output that operates off a universal input of (85 V to 265 V RMS) and provides power factor correction. The unit meets EN61000-3-2 class B input current harmonic specifications.

2 Description

The pre-regulator uses the UCC28528 PFC/PWM combination controller to shape the input current wave to provide power factor correction. This device also controls a 2-W auxiliary bias supply that can be used to control external circuitry. The UCC28220 interleaved PWM provides OVP protection and provides load sharing between the two interleaved boost converters.

3 Thermal Requirements

1. The evaluation module works up to 200 W without external cooling.
2. If the unit is to be run over 200 W, it requires a fan pointed directly at the converter heat sinks.
3. It is important to keep the ambient temperature around the components below 40°C.

4 Electrical Specifications

Table 1. EVM Specifications

	Parameter	Test Conditions	Min	Typ	Max	Unit
V_{IN}	Line input voltage		85		265	V_{RMS}
P_{OUT}	Output power		25		350	W
	Efficiency	350 W	90%			
V_{OUT}	Output voltage		375	380	400	V
THD	Total harmonic distortion	350 W			10%	

5 Schematic

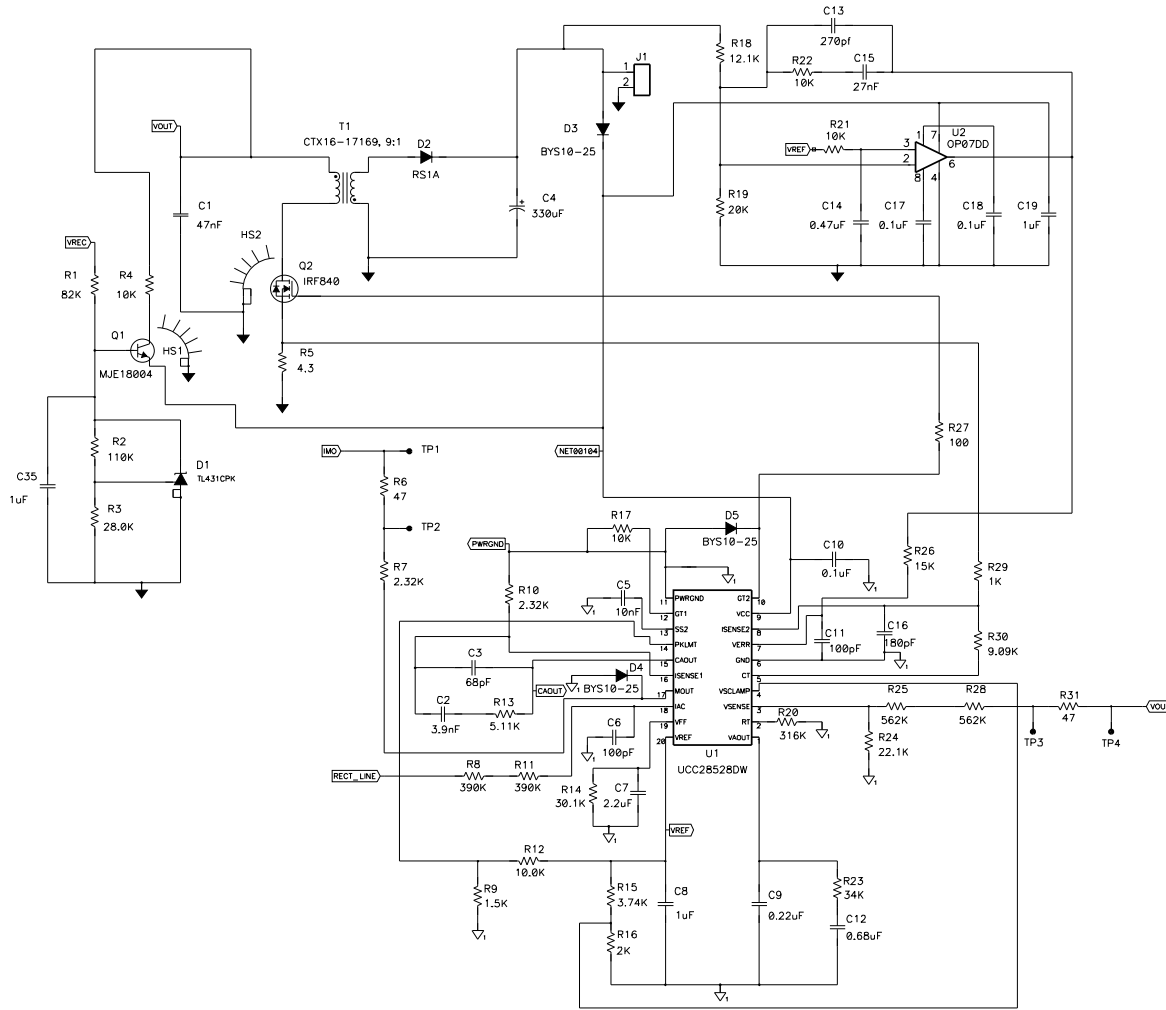

Figure 1. Auxiliary Supply and PFC Control Circuitry

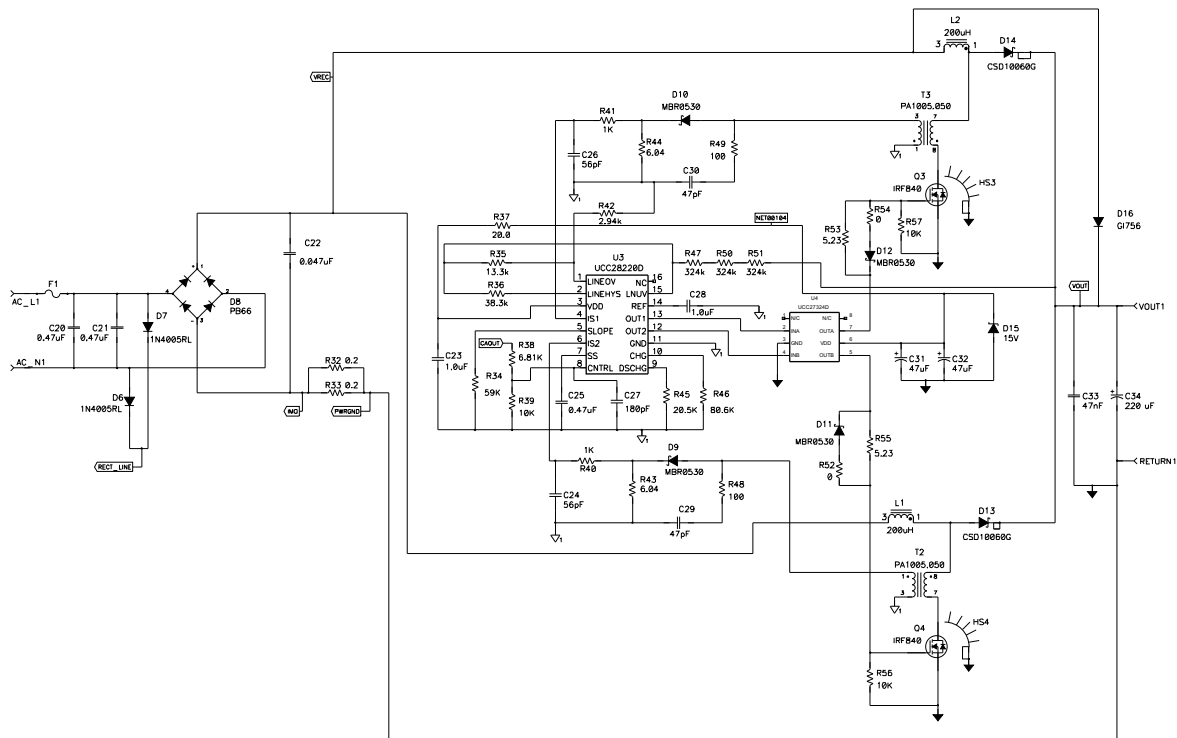

Figure 2. PFC Pre-Regulator Power Stage

6 Test Setup

There are high voltages present on the pre-regulator and it should only be handled by experienced power supply professionals. To evaluate this board as safely as possible the following test set up should be used. An isolation transformer should be connected between the source and unit. Before power is supplied, a volt meter and a resistive or electronic load should be attached to the unit's output.

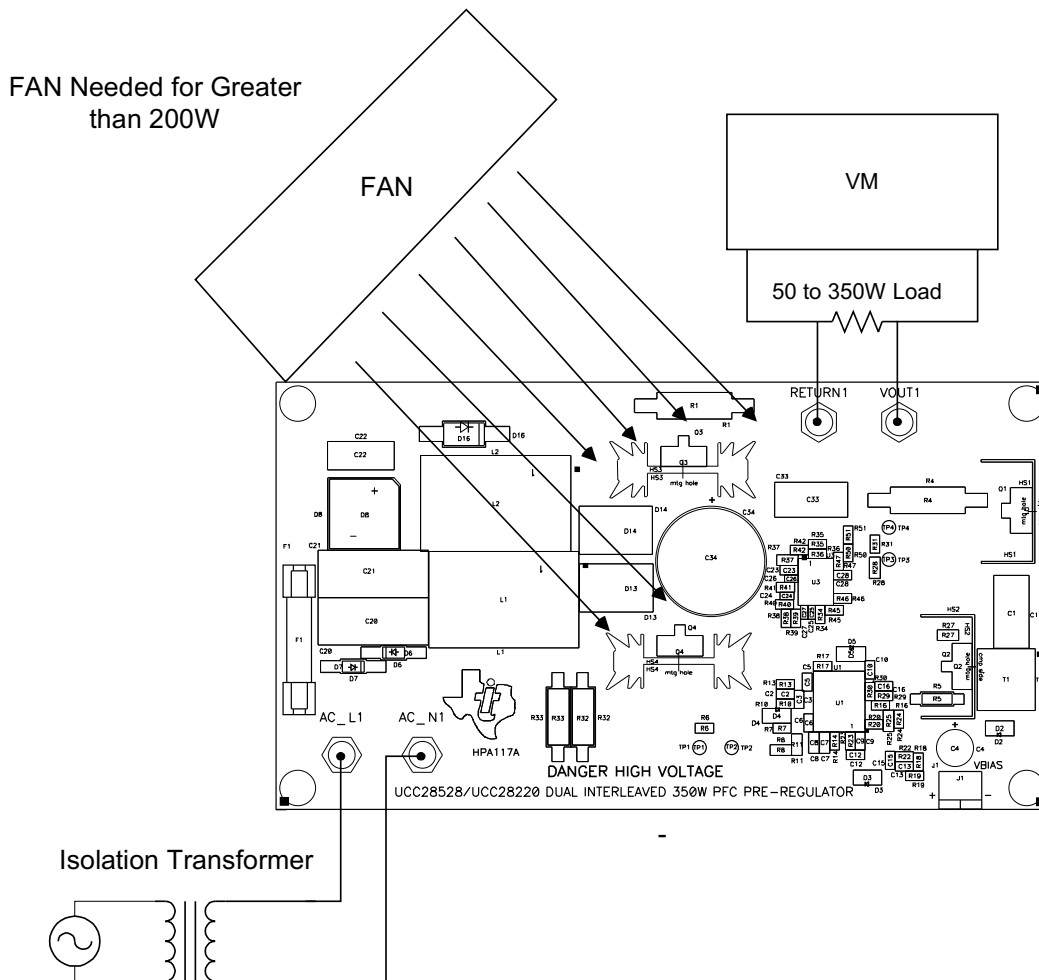

Figure 3. Test Setup

7 Power Up/Power Down

The unit will start up under no load conditions. However, for safety a load should be connected to the output of the device before it is powered up. The unit should also never be handled when power is applied to it or the output voltage is above 50V DC.

WARNING

There are very high voltages on the board and components can and do reach temperatures above 50°C so precautions must be taken in handling the board.

8 Performance Data

The efficiency of the boost pre-regulator is greater than 91% at 20% load. This converter in a normal system would be followed by a step down converter. The new +80 initiative requires the cascaded power supply be 80% efficient at 20% load. This can be accomplished by having the downstream converter being 90% efficient or greater. In high power applications, this can be accomplished with zero voltage switching (ZVS). An active clamp forward using a UCC2894 PWM or a phase shifted full bridge using the UCC2895 PWM could be used to design a step-down converter with greater than 90% efficiency for high power applications.

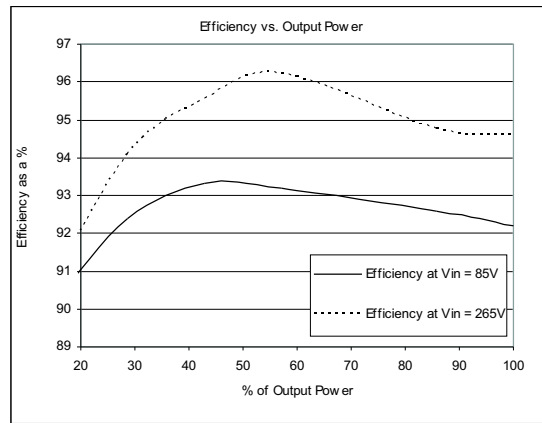

Figure 4. Efficiency vs. Output Power

Figure 5. PF vs. Output Power

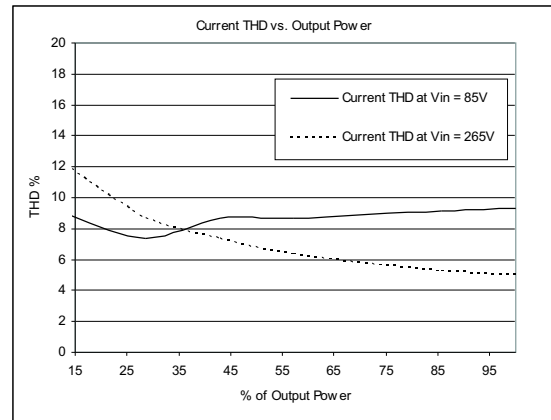

Figure 6. Current THD vs. Output Power

Figure 7. Current Harmonics

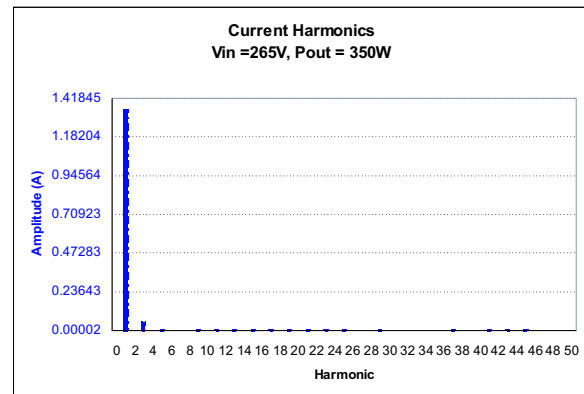

Figure 8. Current Harmonics

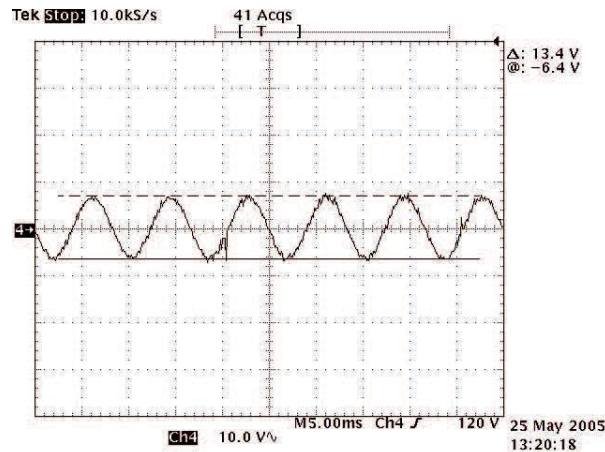

Figure 9. Output Ripple Voltage at Full Load

8.1 Input Ripple Current

Figure 10 shows that the inductor currents cancel each other out leaving the input current wave form clean. CH1 is the rectified line voltage, Ch2 is the inductor current from L1, CH3 is the inductor current of L2, Ch4 is the converter input current; CH1 is the rectified line voltage. Note the conversion ratio for the current waveform is 200 mA/mV.

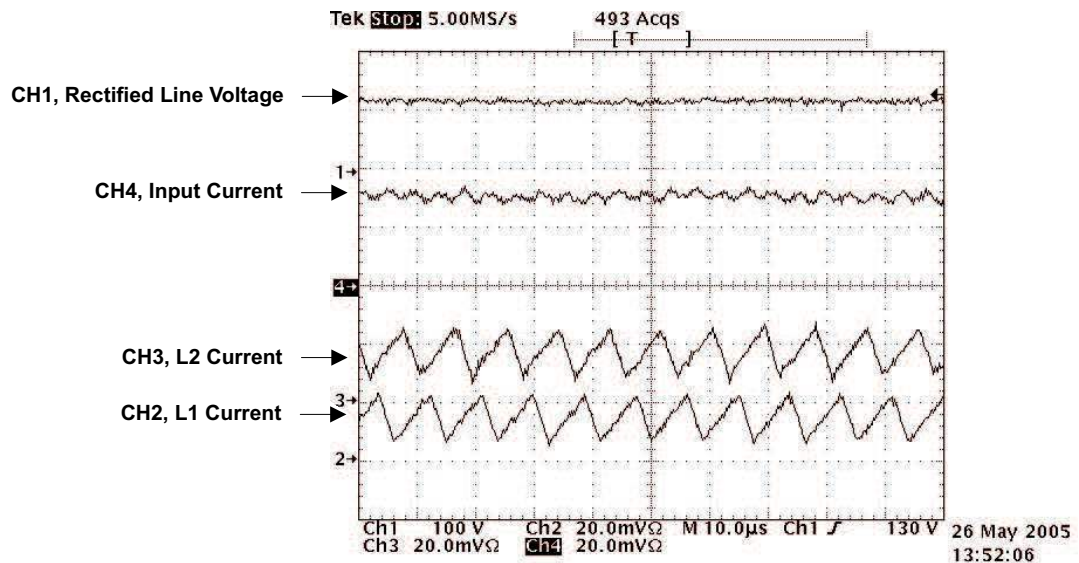

Figure 10. Input Current and Inductor Currents

Figure 11 and Figure 12 show the rectified line voltage (CH1), input current (CH4), and L1 and L2 inductor currents CH2 and CH3 respectively, at maximum load with different line conditions. From these waveforms, it can be observed that the inductor ripple currents are canceling each other out due to the interleaving.

Performance Data

Figure 11. $V_{IN} = 85 \text{ V RMS}$, $P_{OUT} = 350 \text{ W}$

Figure 12. $V_{IN} = 265 \text{ V RMS}$, $P_{OUT} = 350 \text{ W}$

8.2 Startup Characteristics

PFC pre-regulators have a tendency to overshoot during power up. This is due to the voltage loop crossing over at 10 Hz. However, the UCC28528 uses a slew rate comparator that speeds up transient response and reduces overshoot. Figure 13 and Figure 14 show the startup behavior of the EVM at 120-V RMS input at maximum and no load conditions. CH4 is the output voltage and CH3 is the input current. From these figures, it can be observed that there is very little overshoot during startup.

Figure 13. Start-Up at $V_{IN} = 120 \text{ V}$, $P_{OUT} = 350 \text{ W}$

Figure 14. Start-Up at $V_{IN} = 120 \text{ V}$, $P_{OUT} = 0 \text{ W}$

8.3 Line Dropout

The unit was tested under a line dropout condition and the unit came back into regulation within 100 ms. Refer to [Figure 15](#) for details. CH1 is the rectified input voltage and CH2 is the output voltage.

Figure 15. $V_{IN} = 120\text{ V}$, $P_{OUT} = 350\text{ W}$

8.4 Line Transient

A line transient test was conducted with an ac source on the reference design. The line was varied from 120 to 240-V RMS and the transient response was evaluated. From the oscilloscope output shown in [Figure 16](#) it can be observed that the output recovered within 200 ms.

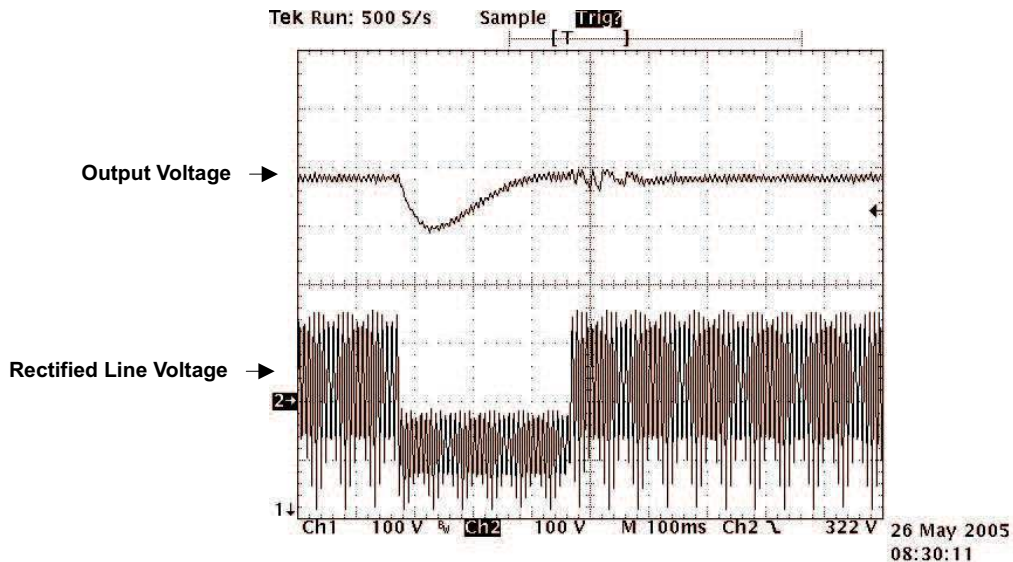

Figure 16. Line Transient, $P_{OUT} = 350\text{ W}$

8.5 2-W Auxiliary Supply (V_{bias})

The unit has a 2-W auxiliary bias supply that was designed to operate with a boost voltage (V_{OUT1}) of 120 V to 400 V. This bias supply is based on a flyback converter and also regulates the PWM/PFC and gate drive circuitry of the evaluation module. Note when V_{BIAS} is not loaded, the gate drive of the flyback is pulse skipping. Once V_{AUX} has been loaded, the gate drive has a fixed duty cycle. Refer to [Figure 17](#), [Figure 18](#), and [Figure 19](#) for details.

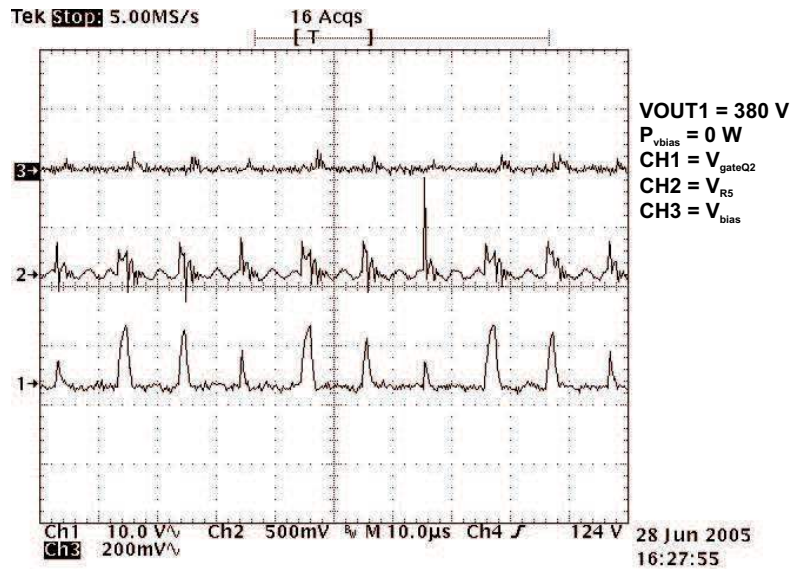

Figure 17. Auxiliary Gate Drive and Current Sense Behavior at No Load

FCC Warnings

This equipment is intended for use in a laboratory test environment only. It generates, uses, and can radiate radio frequency energy and has not been tested for compliance with the limits of computing devices pursuant to subpart J of part 15 of FCC rules, which are designed to provide reasonable protection against radio frequency interference. Operation of this equipment in other environments may cause interference with radio communications, in which case the user at his own expense will be required to take whatever measures may be required to correct this interference.

EVM WARNINGS AND RESTRICTIONS

It is important to operate this EVM within the input voltage range of 85 V to 125 V RMS and the output voltage range of 374 V to 425 V.

Exceeding the specified input range may cause unexpected operation and/or irreversible damage to the EVM. If there are questions concerning the input range, please contact a TI field representative prior to connecting the input power.

Applying loads outside of the specified output range may result in unintended operation and/or possible permanent damage to the EVM. Please consult the EVM User's Guide prior to connecting any load to the EVM output. If there is uncertainty as to the load specification, please contact a TI field representative.

During normal operation, some circuit components may have case temperatures greater than 50°C. The EVM is designed to operate properly with certain components above 50°C as long as the input and output ranges are maintained. These components include but are not limited to linear regulators, switching transistors, pass transistors, and current sense resistors. These types of devices can be identified using the EVM schematic located in the EVM User's Guide. When placing measurement probes near these devices during operation, please be aware that these devices may be very warm to the touch.
