SGP40 – VOC Index for Experts

Version 1.1 Stäfa, August 2020

VOC air pollutants and their sources

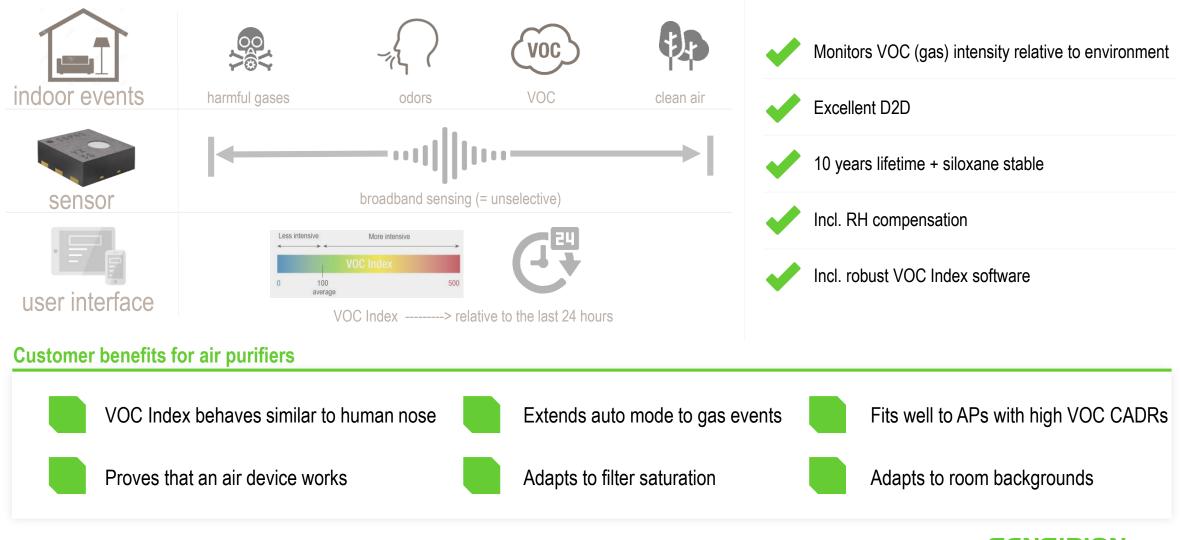

Examples of air pollutants and their source

Harmful gases	 Acetone (paints, glues) Toluene (furniture, mattresses, building products)
Other gases	Ethanol (alcohol, cleaner, perfume)
Odors	 Hydrogen sulfide, volatile sulfuric compounds (rotten food, farts) Ammonia, amines (pet pee)
Smoke	Benzene, nitrosamines (cigarette smoke) Confidential

Monitoring indoor air with the VOC Index

THE SENSOR COMPANY

Three main components of the VOC Index signal

□ How strong? Detects relative intensity of VOC events

SGP40 detects odorless gases as well, but it cannot discriminate between different VOCs.

❑ How long? Detects VOC event duration

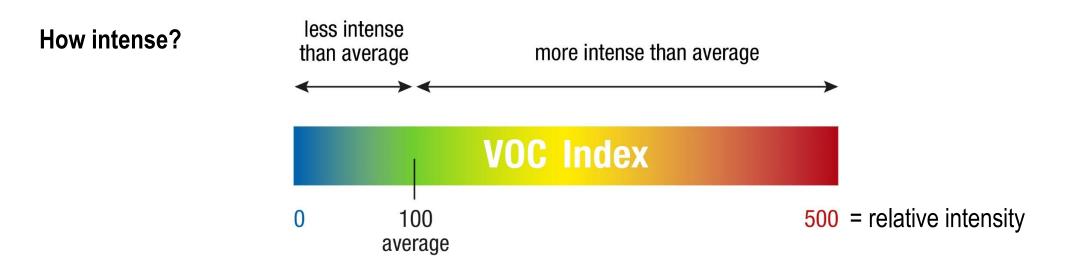

Human nose adapts in a few minutes. SGP40 adapts in a few hours.

□ How often? Informs about VOC event frequency

The VOC Index covers all information needed

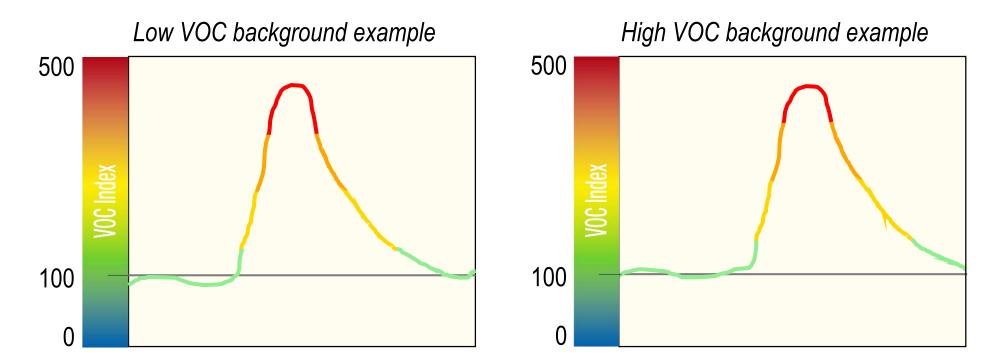

VOC Index...

- □ ...shows changes of intensity relative to the history in the room
- □ ...is referenced to the average of VOCs present over the last 24 h in the room
- □ …behaves similar to a human nose, a MOX sensor is not able to detect the absolute VOC concentration
- □ …starts going back to average VOC Index after 3 h for very long events adapts to background

Visualizing VOC events by means of VOC Index

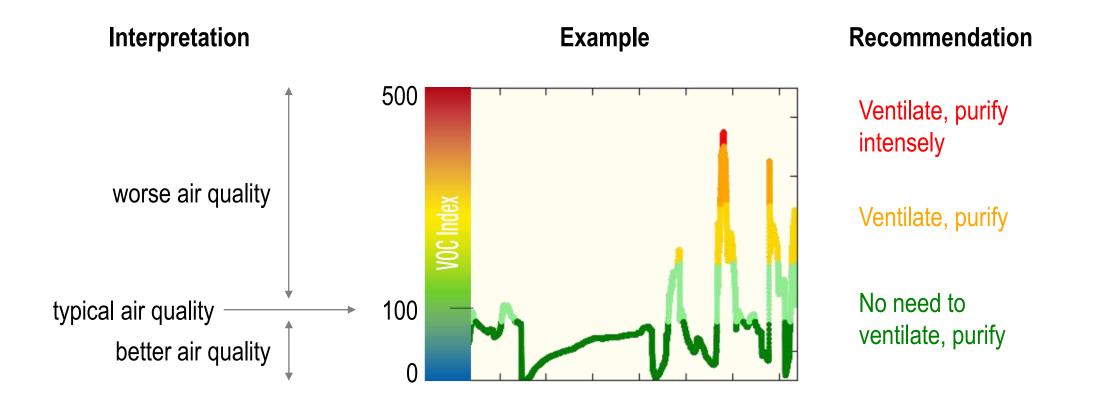

VOC Index visualizes VOC events on a logarithmic scale^{1,2} and relative to typical indoor gas composition during the recent 24 h. This means that level "typical" refers to the typical conditions of the environment. The scale does not represent absolute concentrations.

Next-level air treatment

VOC Index notifies end users or air treatment devices when air pollution changes. Notifications are actionable in environments with low and high VOC backgrounds independent of the absolute VOC concentrations.

Proxy gas ethanol

Laboratory tests typically use a proxy gas for real life VOCs. Sensirion recommends ethanol as proxy gas:

- ✓ The SGP40 sensor sensitivity to ethanol is representative of the ISO-standard VOC mix (*n*-octane + *m*-xylene)¹ and other VOCs occurring in everyday life²
- Ethanol is safe and easy to acquire
- Ethanol enables a simple test setup, only one gas to mix with zero air and humidity

[2] For more details, please ask for the "SGP40 Performance Report"

Laboratory accuracy

After stabilization at 1 ppm of EtOH in a test chamber (equivalent to a small controlled room in a "perfect world")

Note: The shown relationship holds only for the standard VOC test sequence¹ as provided by Sensirion.

Signal flow in the VOC Index driver

VOC Algorithm calculates VOC Index from measurements with SGP40 and SHT sensors:

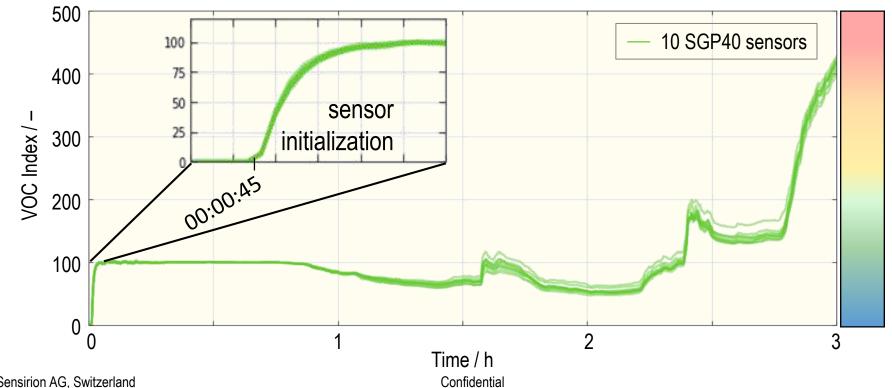

Startup

The VOC Algorithm initializes in two phases:

- 0...1.5 h: fast adaptation to the environment. Signal always initializes in level "typical". • From the beginning, sensor-to-sensor-variation is excellent and fast VOC events are shown.
- >1.5 h: final, slow adaptation.

Even very slow changes in chemical air pollution are now visualized for best user experience.

Long-term behavior

The VOC Algorithm constantly estimates sensor baseline and sensitivity from statistical data of the past 24 h. For this reason, multiple VOC Index signals are most similar if history is equal since startup. When placed into a common room but with different histories, all VOC Index signals usually converge within 1 to 12 h.

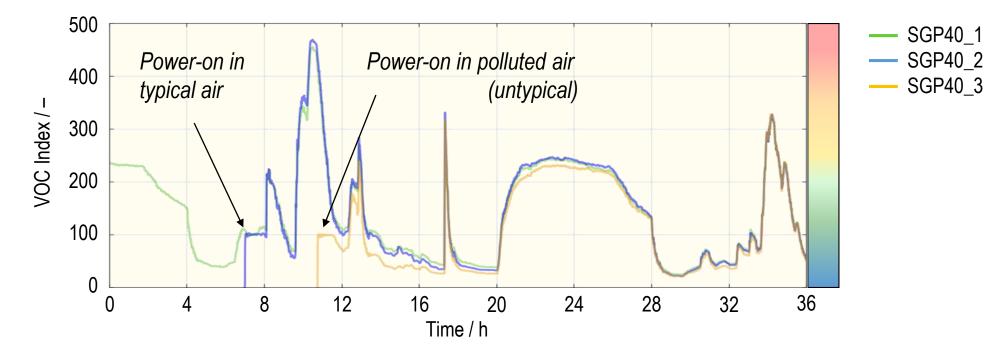

Figure: Three sensor modules with different histories converge after few hours:
