

4A Step-Down Regulator

Description

The LX7180A is a 4A step-down regulator with integrated MOSFETs packaged in a space saving QFN12 2 mm x 2 mm for today's mobile devices. It uses an ultra-fast, constant frequency hysteretic control method to minimize external filter components while maintaining excellent regulation. The LX7180A reference voltage is programmable from 0.6 V to 1.195 V through a high speed (up to 3.4 MHz), bi-directional I2C bus.

The LX7180 operates from 3 V to 5.5 V rails and outputs 0.6 V to 100% of the input voltage.

Cycle-by-cycle current limiting protects against over-current conditions. Hiccup mode provides protection for heavy over-load or short-circuit faults. Thermal protection shuts down the regulator under over-temperature conditions. Over voltage conditions will immediately shut off the output to protect against permanent damage. The LX7180A automatically restarts when all fault conditions are cleared.

Features

- 0-4 A Step-down Regulator
- Operational Input Supply Voltage Range: 3.0 V - 5.5 V (short durations to 6.5 V)
- Hysteretic Control Offers Best Transient Response
- PWM Switching at a Constant 1.65 MHz
- Power Save Mode (PSM) can be Selected to Improve Light Load Efficiency.
- 100% Duty Ratio Operation
- Input Under Voltage and Over Voltage Protection
- Enable and Power Good Function
- I2C Serial Interface at 3.4 Mbps
- Internal Soft-start
- Cycle-by-Cycle Over Current Protection
- Hiccup Mode Protects Against Short Circuit Faults
- Seven Bit Adjustable Reference Voltage via I2C Bus
- RoHS Compliant

Applications

- High Performance HDD
- LCD TV
- Notebook/Netbook
- Server and Workstations
- Video Cards
- PoE Powered Devices Smart Phone

3	LX7180A - 31CLQ-TR					
		LX7180A - xyCLQ-TR*				

Note: 1. * Consult factory for other I2C slave address and set output voltage options.

2. “x” is the 2 LSB bits of the binary I2C slave address (0 to 3).

3. “y” is the set output voltage (0 is 0.6 V, 1 is 0.9 V, 2 is 0.95 V, 3 is 0.97 V).

Pin Description

Pin Number	Pin Designator	Description
1, 10	PVIN	Supply Voltage. Bypass PVIN to ground plane as close as possible to the IC.
2, 11	SW	Switch Output. Drives the external L-C filter.
3, 12	PGND	Power Ground. Connect to ground plane.
4	AGND	Analog Ground. Connect to ground plane.
5	SCL	I2C Serial Clock Digital Input.
6	SDA	I2C Serial Data. Digital Input/Output.
7	FB	Feedback – Analog input, monitors the output voltage either directly or through a resistor divider.
8	EN	Enable – Digital input. Force high to enable the IC.
9	PG	Power Good – Open drain digital output. Pulls low to indicate a fault condition. Requires an external pull up resistor.

Block Diagram

Figure 3 · Block Diagram of LX7180A

Absolute Maximum Ratings

Parameter	Min	Max	Units
PVIN, EN, PG, SCL, SDA, SW to GND	-0.3	7	V
AGND to GND	-0.3	0.3	V
SW to GND (Shorter than 50 ns)	-2	7	V
Junction Temperature Range	-10	150	°C
Storage Temperature Range	-65	150	°C
Peak Lead Soldering Temperature (40s, reflow)		260 (+0, -5)	°C

Note: Performance is not necessarily guaranteed over this entire range. These are maximum stress ratings only. Exceeding these ratings, even momentarily, can cause immediate damage, or negatively impact long-term operating reliability.

Operating Ratings

Performance is generally guaranteed over this range as further detailed are provided in [Electrical Characteristics](#) section.

Parameter	Min	Max	Units
Input Voltage	3.0	5.5	V
Output Voltage	0.6	5.5	V
Output Current (VIN = 3 V to 5 V)	0	4	A
Ambient Temperature	0	85	°C

Note: Corresponding Max Junction Temperature is 125°C.

Thermal Properties

Thermal Resistance(θ_{JA})	Typ	Units
QFN 2x2mm 12L	30	°C/W

Note: The θ_{JA} number assumes no forced airflow. Junction Temperature is calculated using $T_J = T_A + (P_D \times \theta_{JA})$. In particular, θ_{JA} is a function of the PCB construction. The stated number above is for a four-layer board in accordance with JESD-51 (JEDEC).

Electrical Characteristics

Unless otherwise specified, the following specifications apply over the operating ambient temperature of $0^{\circ}\text{C} \leq T_A \leq 85^{\circ}\text{C}$ with the following test conditions: $PV_{IN} = 5\text{ V}$. Typical parameters refers to $T_J = 25^{\circ}\text{C}$. V_{OUT} is connected directly to FB for closed loop tests (default test condition). V_{REF} is set to 0.9 V. V_{OUT} is disconnected from FB for open loop tests. Default registers settings. $I_{load} = 0$. EN=high. GBD specifications are guaranteed by design and/or characterization and are not tested on a production basis. SCL and SDA set to PV_{IN} .

 2. Loads in excess of 100 pF will restrict bus operation speed below 3.4 MHz.

Theory of Operation / Application Information

Basic Operation

The LX7180A compares the FB voltage to an internal reference, V_{REF} . When FB is lower than V_{REF} , the upper switch turns on and the lower switch turns off. When FB is higher than V_{REF} , the upper switch turns off and the lower switch turns on. An internal ramp and a frequency control loop keep the switching frequency constant when in constant conduction mode (CCM) over a wide range of output capacitor values and parasitic components (i.e. ESR, ESL).

At light loads, if enabled, the converter automatically reduces the switching frequency to optimize efficiency.

An integrated I2C bus interface, operating up to 3.4 Mbps, allows the following user programmability to the converter:

- On the fly programming of the reference voltage in 4.7 mV increments.
- Enable / Disable the regulator.
- Enable power save mode (PSM) or limit operation to continuous conduction only (PWM).
- Set the V_{REF} slew rate.
- Enable/Disable VIN over voltage protection.
- Force PGOOD to respond to both under and over voltages or just under voltage.

Setting the Output Voltage

The reference voltage can be programmed with the I2C bus V_{SEL} register value.

$$V_{REF} = 0.6 \text{ V} + V_{SEL} \cdot 0.0047 \text{ V} \dots\dots\dots (2)$$

Where V_{SEL} is programmable from 0 to 127.

Startup

The LX7180A is enabled when EN is high and PVIN rises above the UVLO threshold. At start up, after all the internal bias voltages and currents stabilize, V_{REF} ramps up from 0 V to the target voltage at the defined slew rate. While V_{REF} ramps, PGOOD is held low. At the end of the ramp time, PGOOD is allowed to go high 45 ms after FB has reached the PGOOD rising threshold. During the ramp time, the LX7180A always runs in PSM to allow discontinuous operation. This switchover is independent of the programmed MODE bit setting.

Over Current Protection

The LX7180A protects against all types of short circuit conditions. Cycle-by-cycle over current protection turns off the upper switch when the current exceeds the ICL threshold. When this occurs, the upper switch is kept off for about 360 ns before being allowed to turn on again. After startup, if FB drops below the FB_{UV} threshold, a hiccup sequence will be initiated where both output switches are shut off for 1.2 ms before initiating another soft start. This protects against a crowbar short circuit. FB under voltage detection is not active during startup.

Recommended Output Filter Components

The following tables show the recommended feedback component values (R_{HIGH} , R_{LOW} , C_{ff}) for different input/output voltages, power inductor (L), and output capacitance (C) values that result in optimum closed loop response of the regulator in each case. The estimated crossover frequency is also shown in the table in each case. If the $L \cdot C$ factor exceeds a certain number the regulator would run with low phase margin or become unstable. The L and C range provided in the table provides 30° , or higher of phase margin. Therefore, it is not recommended to increase $L \cdot C$ factor beyond what is given in the table.

It is a good practice to determine L such that the peak-to-peak inductor ripple current in continuous conduction mode operation is roughly equal to 30% of converter's rated output current. In general, increasing the inductance slows down the closed loop response of the regulator. Hence, for applications that require fast line/load transient response, lower inductance values should be preferred over larger ones. Output capacitance can be determined based on desired output ripple voltage staying within the limits provided in the table depending on the inductance value.

Theory of Operation – Continued

Positive Voltage Transitions

After the initial start-up sequence, the output voltage can be programmed to a new value by programming the VSEL register bits and then asserting the GO bit. V_{REF} will transition to the new value at the programmed slew rate. During the transition time the PGOK bit will be low and will go high when the transition completes.

Figure 8 · Positive Voltage Transition

Negative Voltage Transitions

A negative voltage transition occurs when a lower output voltage is programmed into the Vsel register, and initiated by asserting the GO bit. During the transition, when in PFM mode of operation, the upper PGOOD threshold is disabled if set.

Figure 9 · Negative Voltage Transition

If the FB voltage does not drop within 10% of the programmed voltage within 30 ms, then PGOOD will go low. During a transition when in PWM only mode of operation, the PGOOD thresholds will not be disabled but will trigger if the output falls outside the 10% tolerance window around the ramped programmed voltage.

Figure 10 · Negative Voltage Transition PGOOD Fail

Enabling Regulator from I2C Bus

In addition to the EN pin, the regulator can be enabled and disabled via the I2C bus by programming the control register. During disable, the regulator and most of the support circuitry is turned off. However, the I2C bus circuitry is still active and may be programmed.

I2C Interface

I2C Port Functional Description

- Simple two wire, bidirectional, serial communication port.
- Multiple devices on same bus speeds from 400 kbps (FS-Mode) to 3.4 Mbps (HS-Mode).
- SOC Master controls bus.
- Devices listen for the unique address that precedes data.

General I2C Port Description

The LX7180A includes an I2C compatible serial interface, using two dedicated pins: SCL and SDA for I²C clock and data respectively. Each line is externally pulled up to a logic voltage when they are not being controlled by a device on the bus. The serial port is an I²C slave that is clocked by the incoming SCL clock. The I²C port will support both the Fast mode (400 kHz max) and typically the High speed mode (3.4 MHz max). The data on the SDA line must be stable during the HIGH period of the clock signal (SCL). The state of the SDA line can only be changed when SCL is LOW (except for start, stop, and restart).

Register Map

There are five 8-bit user-accessible registers. See the register map [Table 2](#).

I2C Interface (Continued)

Slave Address

In the Table 2, the A1 and A0 are the binary value of the address given in the Ordering Information.

7	6	5	4	3	2	1	0
1	1	0	1	0	A1	A0	R/W

Table 2 · I2C Slave Address

START and STOP Commands

When the bus is idle, both SCL and SDA must be high except in the power up case where they may be held high or low during the system power up sequence.

The STX SOC (bus master) signals START and STOP bits signify the beginning and the end of the I2C transfer. The START condition is defined as the SDA signal transitioning from HIGH to LOW while the SCL line is HIGH. The STOP condition is defined as the SDA transitioning from LOW to HIGH while the SCL is HIGH. The STX SOC acts as the I2C master and always generates the START and STOP bits. The I2C bus is considered to be busy after START condition and free after STOP condition. During data transfer, STX SOC master can generate repeated START conditions. The START and the repeated START conditions are functionally equivalent.

Data Transfers

Data is transferred in 8 bit bytes by SDA with the MSB transferred first. Each byte of data has to be followed by an acknowledge (ACK) bit. The acknowledged related clock pulse is generated by the master. The acknowledge occurs when the transmitter master releases the SDA line to a high state during the acknowledge clock. The SDA line must be pulled down by the receiver slave during the 9th clock pulse to signify acknowledgment. A receiver slave which has been addressed must generate an acknowledgement (“ACK”) after each byte has been received.

After the START condition, the STX SOC (I2C) master sends a chip address. The standard I2C address is seven bits long. Making the eighth bit a data direction bit (R/W). For the eighth bit (LSB), a “0” indicates a WRITE and a “1” indicates a READ. (For clarification, communications are broken up into 9-bit segments, one byte followed by one bit for acknowledging.) The second byte selects the register to which the data will be written. The third byte contains data to write to the selected register.

When a receiver slave doesn’t acknowledge the slave address, the data line must be left HIGH by the slave. The master can then generate a STOP command to abort the transfer. If a slave receiver does acknowledge the slave address but, sometime later in the transfer cannot receive any more data bytes, the master must again abort the transfer. This is indicated by the slave generating the not acknowledge on the first byte to follow.

The slave leaves the data line HIGH and the master generates the STOP command. The data line is also left high by the slave and master after a slave has transmitted a byte of data to the master in a read operation, but this is a not acknowledge that indicates that the data transfer is successful.

Data Transfer Timing for Write Commands

In order to help assure that bad data is not written into the part, data from a write command is only stored after a valid STOP command has been performed.

I2C Electrical Characteristics

The minimum HIGH and LOW periods of the SCL clock are specified in the I2C Specifications, [Table 1](#) determine the maximum bit transfer rates of, 400 kbit/s for Fast-mode devices, and 3.4 Mbits/s for HS-mode Plus. Devices must be able to follow transfers at their own maximum bit rates, either by being able to transmit or receive at that speed or by applying the I2C clock synchronization procedure, which will force the master into a wait state and stretch the LOW period of the SCL signal. Of course, in the latter case the bit transfer rate is reduced.

[Figure 13](#) and [Figure 14](#) show all timing parameters for the HS & FS-mode timing. The 'normal' START condition S does not exist in HS-mode. Timing parameters for Address bits, R/W bit, Acknowledge bit and DATA bits are all the same. Only the rising edge of the first SCL clock signal after an acknowledge bit has a larger value because the external Rp has to pull-up SCL without the help of the internal current-source.

The HS & FS-mode timing parameters for the bus lines are specified in the I2C Specifications [Table 1](#). The minimum HIGH and LOW periods and the maximum rise and fall times of the SCL clock signal determine the highest bit rate.

With an internally generated SCL signal with LOW and HIGH level periods of 200 ns and 100 ns respectively, an HS-mode master fulfills the timing requirements for the external SCL clock pulses (taking the rise and fall times into account) for the maximum bit rate of 3.4 Mbit/s. So a basic frequency of 10 MHz, or a multiple of 10 MHz, can be used by an HS-mode master to generate the SCL signal. There are no limits for maximum HIGH and LOW periods of the SCL clock, and there is no limit for a lowest bit rate.

Timing parameters are independent for capacitive load up to 100 pF for each bus line allowing the maximum possible bit rate of 3.4 Mbit/s. At a higher capacitive load on the bus lines, the bit rate decreases gradually. The timing parameters for a capacitive bus load of 400 pF are specified in I2C Specifications [Table 1](#), allowing a maximum bit rate of 1.7 Mbit/s. For capacitive bus loads between 100 pF and 400 pF, the timing parameters must be interpolated linearly. Rise and fall times are in accordance with the maximum propagation time of the transmission lines SDA and SCL to prevent reflections of the open ends.

Control Register Bit Definition

Bit	Name	Value	Description
Status, Address 00h			
7:3	Reserved		
2	OCP	0-d	Latched to 1 if the over current limit is reached. Write a “1” to reset the status flag.
1	OTP	0-d	Latched to 1 if an over temperature event occurs. Write a “1” to reset the status flag.
0	FB_UVLO	0-d	Latched to 1 if a FB_UVLO event occurs. Write a “1” to reset the status flag.
VSEL, Address 01h, (aka dac)			
7	EN	1-d	Device enabled.
		0	Device disabled.
6:0	VSEL[6:0]		7-bit DAC value to set V_{REF} . The default value is 0.9 V.
Ctrl1, Address 02h, (aka reg2)			
7:6	Reserved	00-d	
5	DLY_DIS	1-d	45 ms delay on PGOOD is disabled when this bit is high.
4	ctrl1	0-d	Not used
3	SW_RATE	1-d	Normal high efficiency rise rate.

Bit	Name	Value	Description
		0	Reduced switch node rise rate.
2	PG_LOHI	1-d	PGOOD will detect both a positive and negative excursion of V_{OUT} from the reference.
		0	PGOOD senses only a negative voltage excursion of V_{OUT} from the reference.
1	VIN_OVP	1-d	When V_{IN} reaches V_{IN} Max, the converter turns off.
		0	V_{IN} OVP disabled. Converter will continue to operate
0	MODE	1-d	PWM – Always run in continuous conduction
		0	PSM – Power Save Mode allows the converter to run in discontinuous conduction
Vendor ID, Address 03h (Read Only)			
7:4	VID[3:0]	0010	Microsemi Vendor ID.
3:2	A1A0	00	Designates the slave address version. These bits will correspond to the two LSB bits.
1:0	VREF	01	Designates the default output voltage version, 00 = 0.6 V, 01 = 0.9 V, 10 = 1.0 V, 11 = 1.1 V.
Ctrl2, Address 04h, (aka reg4)			
7:6	Reserved		
5	GO	1	Write “1” to this bit to start a Vref transition
		0-d	The V_{OUT} is ramped to the default VSEL Value.
4	Discharge	1	When the regulator is disabled, the output voltage is discharged through the SW pin.
		0-d	When the regulator is disabled, the output voltage is not discharged.
3	PGOK	1	Is high when output is in regulation, read only dynamic signal
		0	Is low during a output voltage transition, read only dynamic signal
2:0	SLEW	000	Reserved.
		001	Reserved.
		010	V_{REF} slews at 2.5 mV/ μ s.
		011-d	V_{REF} slews at 5 mV/ μ s; this is the default setting.
		100	V_{REF} slews at 10 mV/ μ s.
		101	V_{REF} slews at 20 mV/ μ s.
		110	V_{REF} slews at 40 mV/ μ s.
		111	Single Step Mode: No slew rate limiting.

Package Outline Dimensions

Figure 17 · QFN 2x2mm 12L Package Dimensions

- Note:**
1. Dimensions do not include mold flash or protrusions; these shall not exceed 0.155 mm (.006") on any side. Lead dimension shall not include solder coverage.
 2. Dimensions are in millimeters, inches for reference only.

Land Pattern Recommendation

Disclaimer:

This PCB land pattern recommendation is based on information available to Microsemi by its suppliers. The actual land pattern to be used could be different depending on the materials and processes used in the PCB assembly, end user must account for this in their final layout. Microsemi makes no warranty or representation of performance based on this recommended land pattern.

Microsemi Corporation (MSCC) offers a comprehensive portfolio of semiconductor and system solutions for communications, defense & security, aerospace and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world's standard for time; voice processing devices; RF solutions; discrete components; security technologies and scalable anti-tamper products; Ethernet solutions; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. Microsemi is headquartered in Aliso Viejo, Calif., and has approximately 3,600 employees globally. Learn more at www.microsemi.com.

Microsemi makes no warranty, representation, or guarantee regarding the information contained herein or the suitability of its products and services for any particular purpose, nor does Microsemi assume any liability whatsoever arising out of the application or use of any product or circuit. The products sold hereunder and any other products sold by Microsemi have been subject to limited testing and should not be used in conjunction with mission-critical equipment or applications. Any performance specifications are believed to be reliable but are not verified, and Buyer must conduct and complete all performance and other testing of the products, alone and together with, or installed in, any end-products. Buyer shall not rely on any data and performance specifications or parameters provided by Microsemi. It is the Buyer's responsibility to independently determine suitability of any products and to test and verify the same.
