

PORTABLE CONSUMER CODEC LOW-POWER, HIGH-FIDELITY INTEGRATED CODEC

TSCS25xx

DESCRIPTION

The TSCS25xx is a low-power, high-fidelity integrated CODEC with 32 bit stereo playback stereo record functionality. In addition to a high-fidelity low-power CODEC, the device integrates stereo true cap-less headphone amplifiers.

The digital audio data ports (both input and output) work in both master or slave mode and supports all common formats including I2S, Left-Justified, Right-Justified and TDM as well as direct Bluetooth PCM mode.

Beyond high-fidelity for portable systems, the device offers an enriched "audio presence" through built-in audio output processing (AOP) DSP engine. The AOP supports 12 Bands of EQ, Psychoacoustic Bass and Treble enhancement, 3D stereo enhancement and Dynamic Range controller to support pro-style Multi-band Compressor/Limiter capability.

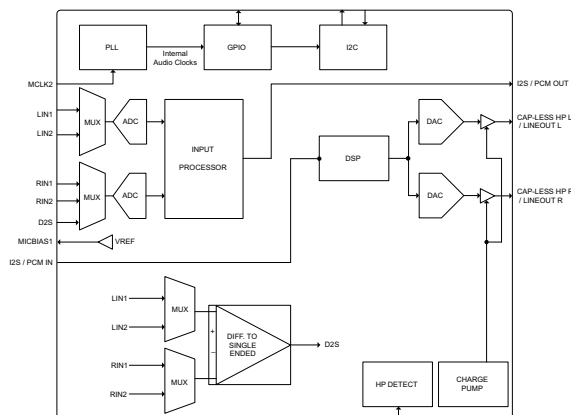

TARGET APPLICATIONS

- IoT / EPC / SBC Motherboards
- Tablet Computers
- Gaming-class Laptops & Desktops
- Portable Gaming Platforms
- Digital Audio Streaming / Connected Audio Accessories
- Bluetooth™-enabled Headphones / Headsets / Docking Stations / Adapters
- Wi-Fi (Miracast, Chromecast, AirPlay® 2)-enabled Headphones / Headsets / Docking Stations
- Lightning-enabled Headphones / Headsets / Docking Stations / Adapters
- Thunderbolt® I/II/III-enabled Headphones / Headsets / Docking Stations / Connectivity Expansion Hubs / Adapters
- MHL / HDMI™-enabled VR / AR Headphones and Headsets

- USB 1.1 / 2.0 / 3.0 / 3.1 Gen 1 / 3.1 Gen 2 / USB-C-enabled Headphones / Headsets / Docking Stations / Connectivity Expansion Hubs / Tablets / Mobile Phones / Tablet & Mobile Phone Cases / Portable Projectors
- Remote Controls / Gaming Controllers with Headphone Jacks

FEATURES

- **On-chip true cap-less headphone driver**
 - 35 mW output power (16Ω)
 - Charge-pump allows true, ground-centered outputs
 - SNR (A-Weighted, no active signal) -124dB
 - Headphone detection logic
- **High fidelity CODEC**
 - 32 bit stereo DAC and 32-bit stereo ADC
 - Sample rates from 8k to 96 kHz
- **Audio Output Processing DSP Engine**
 - 3D stereo enhancement
 - 12 band parametric equalizers
 - Dynamic Range controller
 - Multi-band with independent attack/release and gain
 - Limiter
 - Expander
 - Psychoacoustic Bass and Treble enhancement processing
- **Microphone/line-in interface**
 - Analog microphone or line-in inputs
 - Automatic level control
- **Low power with built in power management**
 - 1.7 V CODEC supports 1Vrms
 - Very low standby and no-signal power consumption
 - 1.8V digital / 1.7V analog supply for low power
- **2-wire (I²C compatible) control interface**
- **Flexible Digital Audio Data Interface**
 - Supports Bluetooth PCM
 - Adjustable Frame Length
 - Selectable Frame Sync
 - Flexible word length (16, 24, 32-bit)
 - I2S, Left-Justified, Right-Justified
 - Flexible word length (16,24,32-bit)
- **Package**
 - 40-pin, 5x5mm, QFN

1. OVERVIEW

1.1. Block Diagram

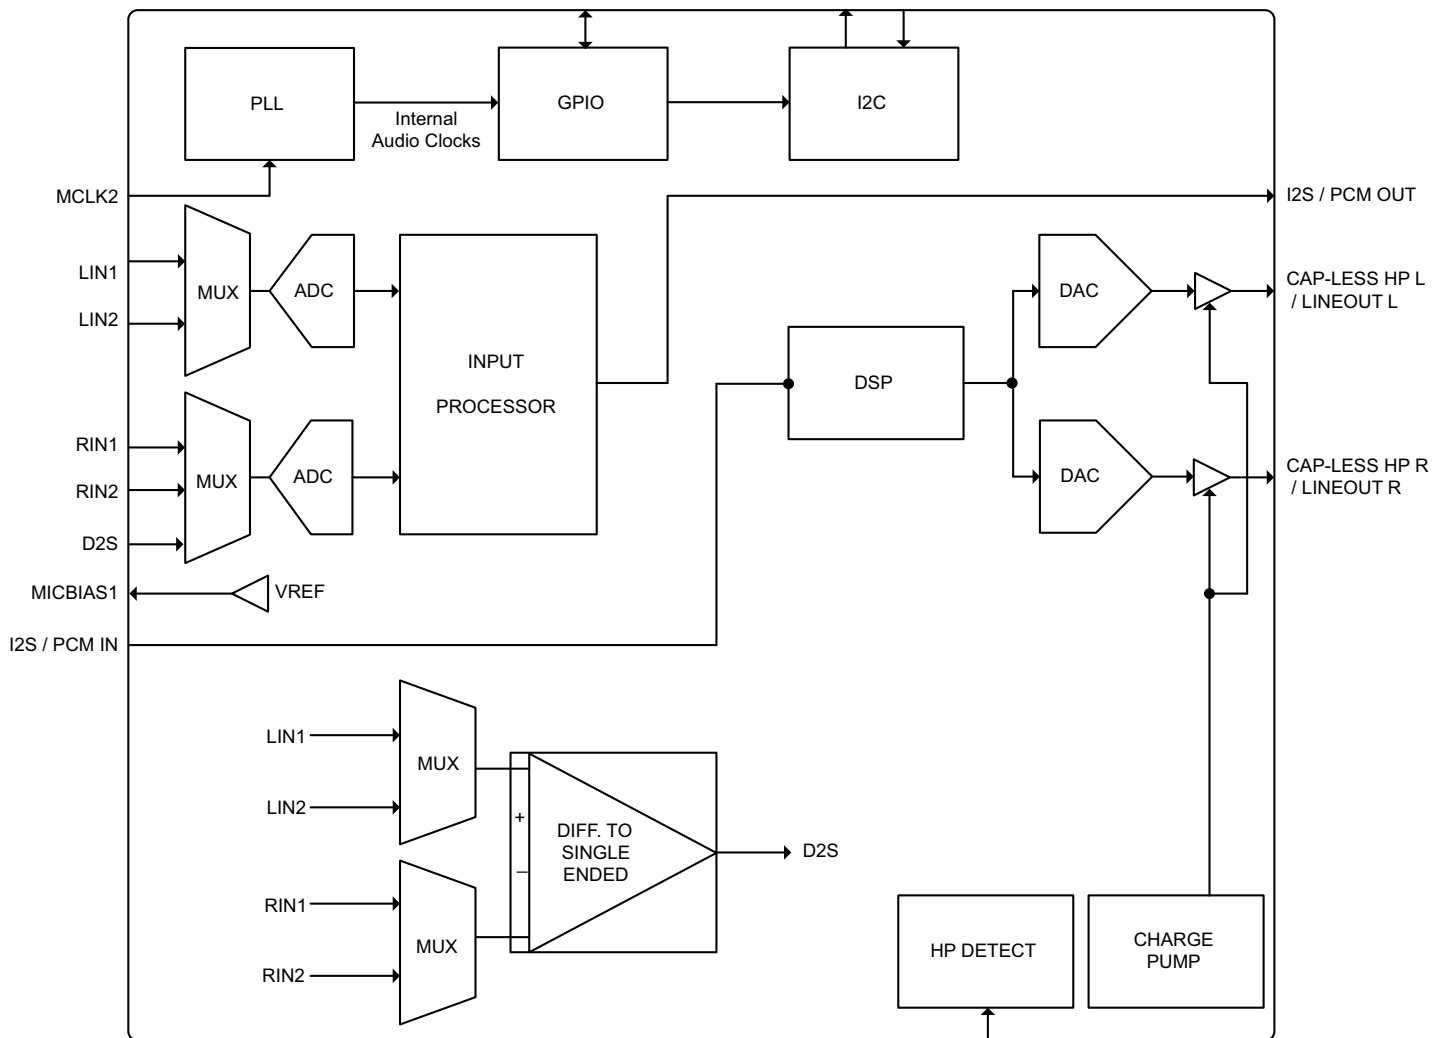

Figure 1. Block Diagram

1.2. Audio Outputs

The TSCS25xx provides :

- A line-out/cap less stereo headphone port with ground referenced outputs, capable of driving headphones without requiring an external DC blocking capacitor.

Each endpoint features independent volume controls, including a soft-mute capability which can slowly ramp up or down the volume changes to avoid unwanted audio artifacts.

The TSCS25xx output signal paths consist of digital filters, DACs and output drivers. The digital filters and DACs are enabled when the TSCS25xx is in 'playback only' or 'record and playback' mode. The output drivers can be separately enabled by individual control bits.

TSCS25xx

Portable Consumer CODECs

The digital filter and audio processing block processes the data to provide volume control and numerous sound enhancement algorithms. Two high performance sigma-delta audio DACs convert the digital data into analog. The digital audio data is converted to over sampled bit streams using digital interpolation filters, which then enters sigma-delta DACs, and become converted to high quality analog audio signals.

1.3. Audio Inputs

The TSCS25xx provides multiple digital and analog audio inputs. Audio inputs include

- One digital audio input
 - support all common I2S formats as well as direct Bluetooth PCM mode
- Three mux selectable stereo analog line/microphone inputs with selectable differential input option

The device provides input gain control, separate volume controls, automatic leveling capability, and programmable microphone boost to smooth input recording. A programmable silence/noise gate “floor” or “threshold” can be set to minimize background noise.

2. POWER MANAGEMENT

2.1. Control Registers

The TSCS25xx has control registers to enable system software to control which functions are active. To minimize power consumption, unused functions should be disabled. To avoid audio artifacts, it is important to enable or disable functions in the correct order. Depending on user case, customer can contact tempo for information.

2.1.1. Power Management Register 1

Register Address	Bit	Label	Type	Default	Description
R26(1Ah) PWRM1	7	BSTL	RW	0	Analog in Boost Left 0 = Power down 1 = Power up
	6	BSTR	RW	0	Analog in Boost Right 0 = Power down 1 = Power up
	5	PGAL	RW	0	Analog in PGA Left 0 = Power down 1 = Power up
	4	PGAR	RW	0	Analog in PGA Right 0 = Power down 1 = Power up
	3	ADCL	RW	0	ADC Left 0 = Power down 1 = Power up
	2	ADCR	RW	0	ADC Right 0 = Power down 1 = Power up
	1	MICB	RW	0	MICBIAS 0 = Power down 1 = Power up
	0	DIGENB	RW	0	Master clock disable 0: master clock enabled 1: master clock disabled

Table 1. PWRM1 Register

2.1.2. Power Management 2 Register

Register Address	Bit	Label	Type	Default	Description
R27(1Bh) PWRM2	7	D2S	RW	0	Analog in D2S AMP 0 = Power down 1 = Power up
	6	HPL	RW	0	LHP Output Buffer + DAC 0 = Power down 1 = Power up
	5	HPR	RW	0	RHP Output Buffer + DAC 0 = Power down 1 = Power up
	4	SPKL	RW	0	LSPK Output Buffer 0 = Power down 1 = Power up
	3	SPKR	RW	0	RSPK Output Buffer 0 = Power down 1 = Power up
	2	RSVD	RW	0	Reserved(bit implemented but unused)
	1	RSVD	RW	0	Reserved (bit implemented bur unused)
	0	VREF	RW	0	VREF (necessary for all other functions) 0 = Power down 1 = Power up

Table 2. PWRM2 Register

2.2. Stopping the Master Clock

In order to minimize digital core power consumption, the master clock may be stopped in Standby and OFF modes by setting the DIGENB bit (R26, bit 0).

Register Address	Bit	Label	Type	Default	Description
R26(1Ah) PWRM1	0	DIGENB	RW	0	Master clock disable 0: master clock enabled 1: master clock disabled

Table 3. Stopping the Master Clock

Note: The control bits ADCL, ADCR, HPL and HPR must be set to zero for 100ms before DIGENB is set. It is recommended that during development, the developer should endeavor to observe HPL and HPR ports ramp down completely. Failure to follow this procedure may cause pops or if the wait period is less than 1mS, may prevent the DACs and ADCs from re-starting correctly.

3. OUTPUT AUDIO PROCESSING

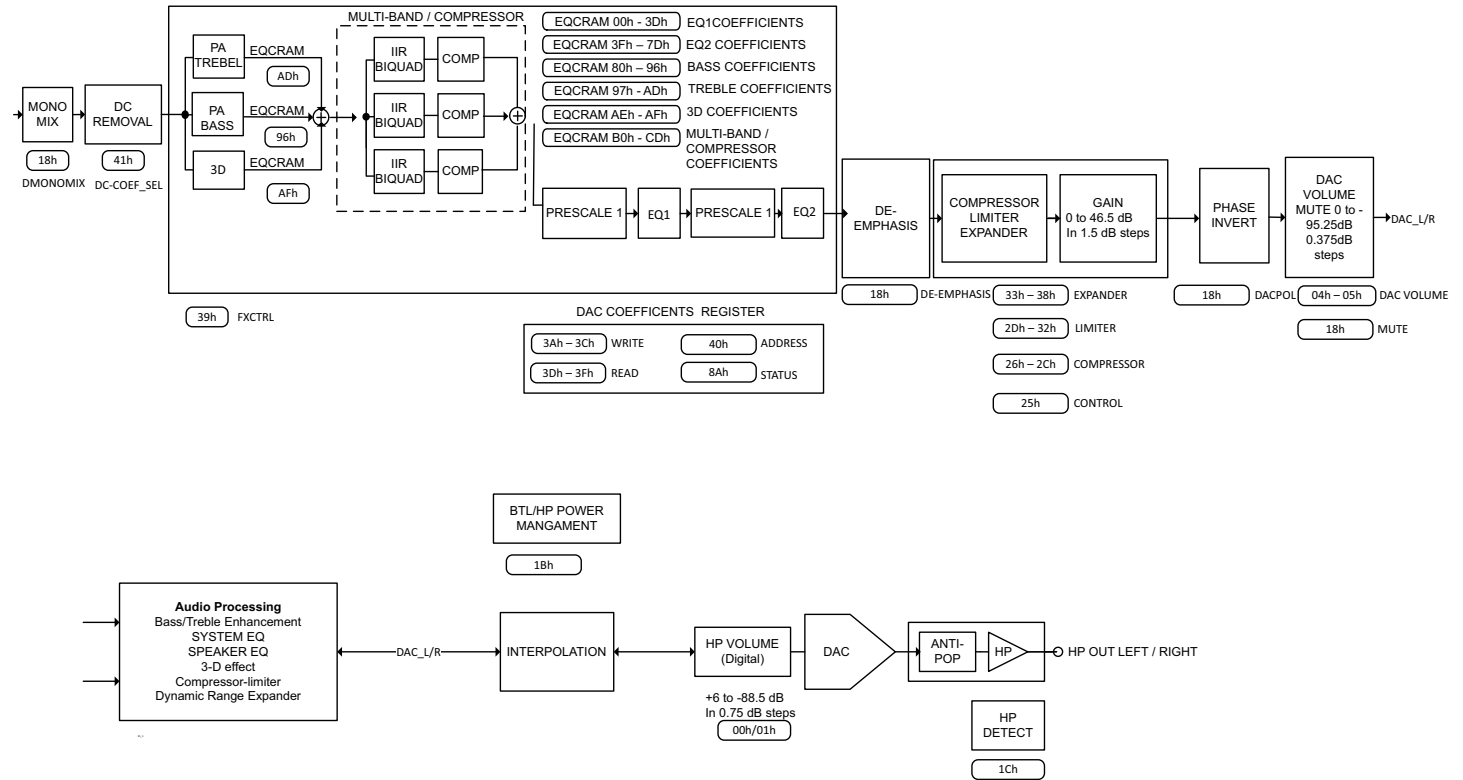

Figure 2. Output Audio Processing

3.1. DC Removal

Before processing, a DC removal filter removes the DC component from the incoming audio data. The DC removal filter is programmable, and can be bypassed by setting `dc_bypass` bit (R31 CONFIG0, bit1). The DC removal is active by default.

Register Address	Bit	Label	Type	Default	Description
R65 (41h) DCOFSEL	7:3	–	R	0	Reserved for future use.
	2:0	-	RW	5	0: dc_coef = 24'h008000; //2 ⁸ -8 1: dc_coef = 24'h004000; //2 ⁹ -9 2: dc_coef = 24'h002000; //2 ¹⁰ -10 3: dc_coef = 24'h001000; //2 ¹¹ -11 4: dc_coef = 24'h000800; //2 ¹² -12 5: dc_coef = 24'h000400; //2 ¹³ -13 6: dc_coef = 24'h000200; //2 ¹⁴ -14 7: dc_coef = 24'h000100; //2 ¹⁵ -15

Table 4. DCOFSEL Register

Register Address	Bit	Label	Type	Default	Description
R31 (1Fh) CONFIG0	1	dc_bypass	RW	0	1 = bypass DC removal filter 0 = DC removal filter active

Table 5. DC removal filter bypass

3.2. Volume Control

The signal volume can be controlled digitally, across a gain and attenuation range of -95.25dB to 0dB (0.375dB steps). The level of attenuation is specified by an eight-bit code, 'DACVOL_x', where 'x' is L, or R. The value "00000000" indicates mute; other values select the number of 0.375dB steps above -95.625dB for the volume level.

The Volume Update bits control the updating of volume control data; when a bit is written as '0', the Left Volume control associated with that bit is updated when ever the left volume register is written and the Right Volume control is updated when ever the right volume register is written. When a bit is written as '1', the left volume data is placed into an internal holding register when the left volume register is written and both the left and right volumes are updated when the right volume register is written. This enables a simultaneous left and right volume update.

Register Address	Bit	Label	Type	Default	Description
R4 (04h) DACVOLL	7:0	DACVOL_L [7:0]	RW	FF (0dB)	Left DAC Volume Level 0000 0000 = Digital Mute 0000 0001 = -95.25dB 0000 0010 = -94.875dB ... 0.375dB steps up to 1111 1111 = 0dB Note: If DACVOLU is set, this setting will take effect after the next write to the Right Input Volume register.
R5 (05h) DACVOLRI	7:0	DACVOL_R [7:0]	RW	FF (0dB)	Right DAC Digital Volume Level 0000 0000 = Digital Mute 0000 0001 = -95.25dB 0000 0010 = -94.875dB ... 0.375dB steps up to 1111 1111 = 0dB

Table 6. DACVOLL/DACVOLR Register

3.2.1. Volume Control Registers

Register Address	Bit	Label	Type	Default	Description
R10 (0Ah) VUCTL	7	ADCFade	RW	1	1 = volume fades between old/new value 0 = volume/mute changes immediately
	6	DACFade	RW	1	1 = volume fades between old/new value 0 = volume/mute changes immediately
	5	RSVD	R	0	Reserved for future use.
	4	INVOLU	RW	0	0 = Left input volume updated immediately 1 = Left input volume held until right input volume register written.
	3	ADCVOLU	RW	0	0 = Left ADC volume updated immediately 1 = Left ADC volume held until right ADC volume register written.
	2	DACVOLU	RW	0	0 = Left DAC volume updated immediately 1 = Left DAC volume held until right DAC volume register written.
	1	SPKVOLU	RW	0	0 = Left speaker volume updated immediately 1 = Left speaker volume held until right speaker volume register written.
	0	HPVOLU	RW	0	0 = Left headphone volume updated immediately 1 = Left headphone volume held until right headphone volume register written.

Table 7. VUCTL Register

The output path may be muted automatically when a long string of zero data is received. The length of zeros is programmable and a detection flag indicates when a stream of zero data has been detected.

Register Address	Bit	Label	Type	Default	Description
R33 (21h) GAINCTL	7	zerodet_flag	R	0	1 = zero detect length exceeded.
	6	RSVD	R	0	Reserved for future use.
	5:4	zerodetlen	RW	2	Enable mute if input consecutive zeros exceeds this length. 0 = 512, 1 = 1k, 2 = 2k, 3 = 4k samples
	3	auto_pwr	R	0	power down when mute detected
	2	auto_mute	RW	1	1 = auto mute if detect long string of zeros on input
	1	RSVD	R	0	Reserved for future use.
	0	RSVD	R	0	Reserved for future use.

Table 8. GAINCTL Register

3.3. Parametric Equalizer

The TSCS25xx has a 12-band digital parametric equalizer (a dual 6-band parametric equalizer: EQ1 and EQ2) to enable fine tuning of the audio response and preferences for a given system. Each EQ may be enabled or disabled independently.

3.3.1. Prescaler & Equalizer Filter

The dual 6-band parametric equalizer consists of a Prescaler and 6 cascaded 6-tap IIR Filters. The Prescaler allows the input to be attenuated prior to the EQ filters in case the EQ filters introduce gain, and would thus clip if not prescaled.

Tempo provides a tool to enable an audio designer to determine appropriate coefficients for the equalizer filters. The filters enable the implementation of a 6-band parametric equalizer with selectable frequency bands, gain, and filter characteristics (high, low, or bandpass)

Figure 3. Prescaler & EQ Filters

The figure below shows the structure of a single EQ filter. The $a(0)$ tap is always normalized to be equal to 1 (400000h). The remaining 5 taps are 24-bit twos complement format programmable coefficients. ($-2 < \text{coefficient} < +2$)

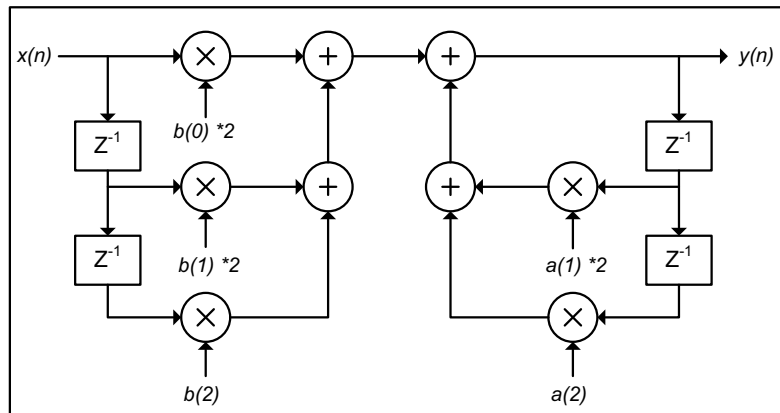

Figure 4. 6-Tap IIR Equalizer Filter

3.3.2. EQ Filter Enable Register

Register Address	Bit	Label	Type	Default	Description
R32 (20h) CONFIG1	7	EQ2_EN	R/W	0	EQ bank 2 enable 0 = second EQ bypassed 1 = second EQ enabled
	6:4	EQ2_BE[2:0]	R/W	0	EQ2 band enable. When the EQ is enabled the following EQ stages are executed. 0 - Prescale only 1 - Prescale and Filter Band 0 ... 6 - Prescale and Filter Bands 0 to 5 7 - RESERVED
	3	EQ1_EN	R/W	0	EQ bank 1 enable 0 = first EQ bypassed 1 = first EQ enabled
	2:0	EQ1_BE[2:0]	R/W	0	EQ1 band enable. When the EQ is enabled the following EQ stages are executed. 0 - Prescale only 1 - Prescale and Filter Band 0 ... 6 - Prescale and Filter Bands 0 to 5 7 - RESERVED

Table 9. CONFIG1 Registers

3.3.3. DACCRAM Write/Read Registers

Below registers provide the 24-bit data holding registers used when doing indirect writes/reads to the DAC Coefficient RAM.

3.3.3.1. DAC Coefficient Write Data Low Register

Register Address	Bit	Label	Type	Default	Description
R58 (3Ah) DACCRWRL	7:0	DACCRWD[7:0]	R/W	0	Low byte of a 24-bit data register, contains the values to be written to the DACCRAM. The address written will have be specified by the DACCRAM Address fields.

Table 10. DACCRWRL Register

3.3.3.2. DAC Coefficient Write Data Mid Register

Register Address	Bit	Label	Type	Default	Description
R59 (3Bh) DACCRWRM	7:0	DACCRWD[15:8]	R/W	0	Middle byte of a 24-bit data register, contains the values to be written to the DACCRAM. The address written will have be specified by the DACCRAM Address fields.

Table 11. DACCRWRM Register

3.3.3.3. *DAC Coefficient WRITE Data High Register*

Register Address	Bit	Label	Type	Default	Description
R60 (3Ch) DACCRWRH	7:0	DACCRWD[23:16]	R/W	0	High byte of a 24-bit data register, contains the values to be written to the DACCRAM. The address written will have be specified by the DACCRAM Address fields.

Table 12. DACCRWRH Register

3.3.3.4. *DAC Coefficient Read Data Low Register*

Register Address	Bit	Label	Type	Default	Description
R61 (3Dh) DACCRDL	7:0	DACCRRD[7:0]	R	0	Low byte of a 24-bit data register, contains the contents of the most recent DACCRAM address read from the RAM. The address read will have been specified by the DACCRAM Address fields.

Table 13. DACCRDL Register

3.3.3.5. *DAC Coefficient Read Data Mid Register*

Register Address	Bit	Label	Type	Default	Description
R62 (3Eh) DACRRDM	7:0	DACCRRD[15:8]	R	0	Middle byte of a 24-bit data register, contains the contents of the most recent DACCRAM address read from the RAM. The address read will have been specified by the DACCRAM Address fields.

Table 14. DACRRDM Register

3.3.3.6. *DAC Coefficient Read Data High Register*

Register Address	Bit	Label	Type	Default	Description
R63 (3Fh) DACRRDH	7:0	DACCRRD[23:16]	R	0	High byte of a 24-bit data register, contains the contents of the most recent DACCRAM address read from the RAM. The address read will have been specified by the DACCRAM Address fields.

Table 15. DACRRDH Register

3.3.4. DACCRAM Address Register

This 8-bit register provides the address to the internal RAM when doing indirect writes/reads to the DAC Coefficient RAM

Register Address	Bit	Label	Type	Default	Description
R64 (40h) DACCRADDR	7:0	DACCRADD	R/W	0	Contains the address (between 0 and 255) of the DACCRAM to be accessed by a read or write. This is not a byte address--it is the address of the 24-bit data item to be accessed from the DACCRAM. This address is automatically incremented after writing to DACCRAM_WRITE_HI or reading from DACCRAM_READ_HI (and the 24 bit data from the next RAM location is fetched.)

Table 16. DACCRADDR Register

3.3.5. DACCRAM STATUS Register

This control register provides the write/read enable when doing indirect writes/reads to the DAC Coefficient RAM.

Register Address	Bit	Label	Type	Default	Description
R138 (8Ah) DACCRSTAT	7	DACCRAM_Busy	R	0	1 = read/write to DACCRAM in progress, cleared by HW when done.
	6:0	RSVD	R	0	Reserved

Table 17. DACCRSTAT Register

3.3.6. Equalizer, Bass, Treble Coefficient & Equalizer Prescaler RAM

The DAC Coefficient RAM is a single port 176x24 synchronous RAM. It is programmed indirectly through the Control Bus in the following manner as shown in the figure below:

- 1 Write target address to DACCRAM_ADDR register. (DAC Coefficient data is pre-fetched even if we don't use it)
 - a Start command followed by the Device Address and Write flag
 - b Register Address (DACCRAM_ADDR register address)
 - c Register Data (DACCRAM address to be held in DACCRAM_ADDR)
- 2 Start a multiple write cycle
 - a Start command followed by the Device Address and Write Flag
 - b Register Address of the DACCRAM_WRITE_LO register
 - c Write D7:0 to the DACCRAM_WRITE_LO register
 - d Write D15:8 to the DACCRAM_WRITE_MID register
 - e Write D23:16 to the DACCRAM_WRITE_HI register
- 3 On successful receipt of the DACCRAM_WRITE_HI data, the part will automatically start a write cycle. The DACCRAM_Busy bit will be set high to indicate that a write is in progress.
- 4 On completion of the internal write cycle, the DACCRAM_Busy bit will be 0 (when operating the control interface at high speeds software must poll this bit to ensure the write cycle is complete before starting another write cycle.)

TSCS25xx

Portable Consumer CODECs

5 The bus cycle may be terminated by the host or steps 2-3 may be repeated for writes to consecutive DAC Coefficient RAM locations.

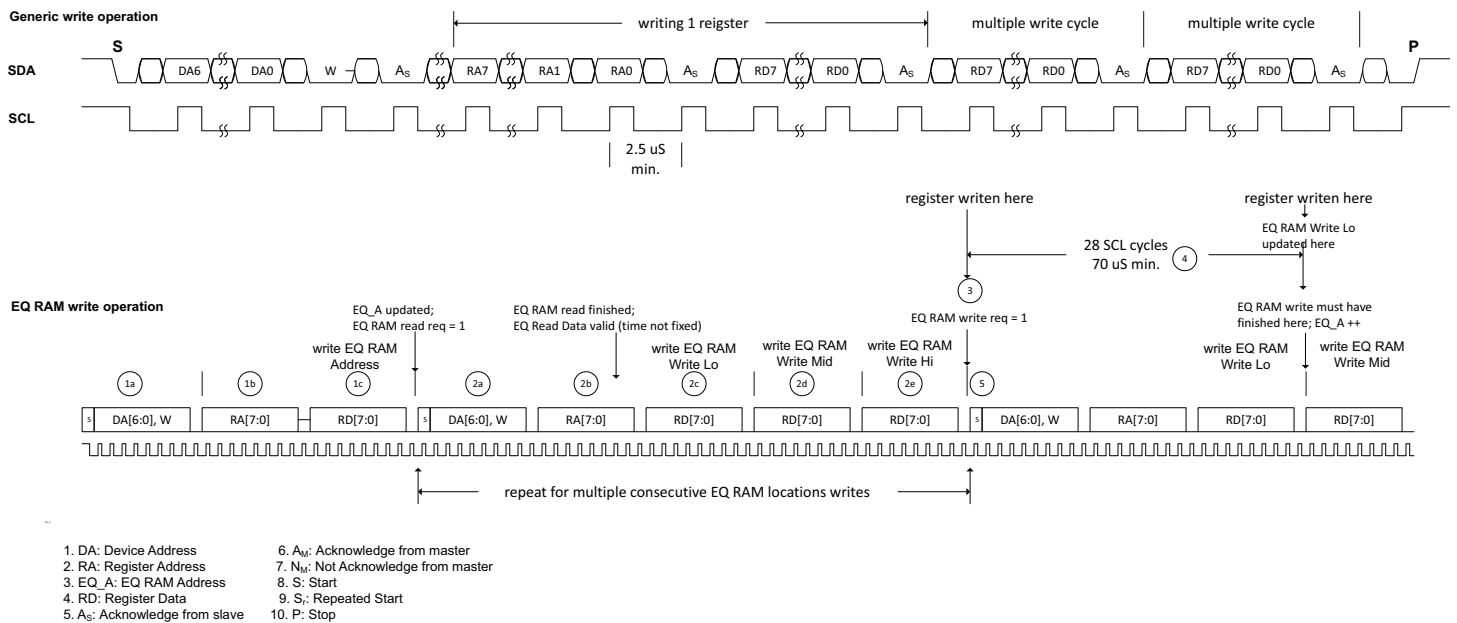

Figure 5. DAC Coefficient RAM Write Sequence

Reading back a value from the DACRAM is done in this manner:

- 1 Write target address to DACCRAM_ADDR register.(DAC Coefficient data is pre-fetched for read even if we don't use it)
 - a Start command followed by the Device Address and Write flag
 - b Register Address (DACCRAM_ADDR register address)
 - c Register Data (DACCRAM address to be held in DACCRAM_ADDR)
- 2 Start (or repeat start) a write cycle to DACCRAM_READ_LO and after the second byte (register address) is acknowledged, go to step 3. (Do not complete the write cycle.)
 - a Start command followed by the Device Address and Write Flag
 - b Register Address of the DACCRAM_READ_LO register
- 3 Signal a repeat start, provide the device address, and indicate a read operation
- 4 Read D7:0 (register address incremented after ack by host)
- 5 Read D15:8 (register address incremented after ack by host)
- 6 Read D23:16 (register address incremented and next DAC Coefficient location pre-fetched after ack by host)
- 7 The host stops the bus cycle

To repeat a read cycle for consecutive DAC Coefficient RAM locations:

- 8 Start (or repeat start instead of stopping the bus cycle in step 7) a write cycle indicating DACCRAM_RD_LO as the target address.
- 9 After the second byte is acknowledged, signal a repeated start.
- 10 Indicate a read operation
- 11 Read the DACCRAM_READ_LO register as described in step 4
- 12 Read the DACCRAM_READ_MID register as described in step 5

TSCS25xx

Portable Consumer CODECs

- 13 Read the DACCRAM_READ_HI register as described in step 6
- 14 Repeat steps 8-13 as desired

1. All B0 coefficients are set to unity (400000h) by default. All others, including M1 and M2, are 0 by default.
2. NLF coefficients (M1, M2) have a range defined as +/-8, with 1 sign bit, 3 integer bits, and 20 fraction bits. So, unity for these values is 100000h. This is as opposed to the rest of the coefficient RAM, which has a range defined as +/-2, with 1 sign bit, 1 integer bit, and 22 fraction bits.

3.4. Gain and Dynamic Range Control

The volume for a given channel is controlled by the DACVOL and HPVOL registers. If the result of the gain multiply step would result in overflow of the output word width, the output is saturated at the max positive or negative value. In addition to simple gain control, the TSCS25xx also provides sophisticated dynamic range control including limiting, dynamic range compression, and dynamic range expansion functions.

3.5. Multi-band Compressor

Figure 7. Gain Compressor, Output vs Input

3.5.1. Overview

The TSCS25xx output processing includes a multi-band compressor that improves sound from small loudspeakers typically used in portable devices. Three independent compressor blocks are each preceded by a Bi-quad processing block that filters the incoming audio so that each compressor operates on a select range of audio frequencies. The advantage of multiband compression over full-bandwidth (full-band, or single-band) compression is that audible gain “pumping” can be reduced. When using single band compressors high energy audio content in a narrow range of frequencies can cause the volume of the entire audio frequency band to be affected thus causing the audio signal level to audibly “pump”. This pumping of the audio signal level can be distracting. A multi-band compressor can effectively eliminate or reduce the pumping to insignificant levels. An example of a crossover is at the bottom of Figure 8

Each band has independent attack and release as well as independent gain settings

Figure 8. block diagram Multiband compressor

Each band in the Multi-band Compressor is comprised of a single stage 6-tap IIR (Bi-quad) filter followed by a compressor block. The Bi-quad filter coefficients are written using the Parametric Equalizer Registers. The purpose of the Bi-quad block is to provide a filter function for each Compressor band. The filter configuration can be lowpass, bandpass or highpass.

A basic block diagram of the compressor is shown below:

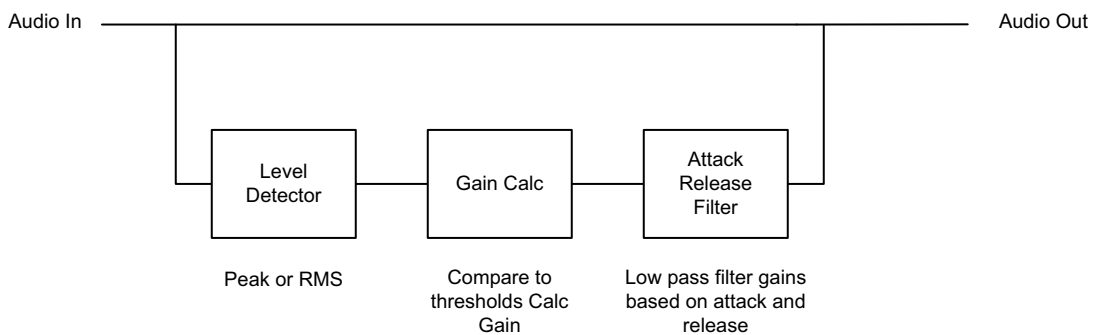

Figure 9. Compressor block diagram

As this diagram shows, there are 3 primary components of the compressor.

1. **Level Detector:** The level detector, detects the level of the incoming signal. Since the comp/limiter is designed to work on blocks of signals, the level detector will either find the peak value of the block of samples to be processed or the rms level of the samples within a block.
2. **Gain Calculation:** The gain calculation block is responsible for taking the output of the level detector and calculating a target gain based on that level and the compressor and expander Compression region gain calculation: In the compression region, the gain calculation is:

$$\text{Atten}(\text{in db}) = (1-1/\text{ratio}) (\text{threshold}(\text{in db}) - \text{level}(\text{in db}));$$

- For example,
 - Ratio = 4:1 compression
 - Threshold = -16db
 - Level = -4 db

The required attenuation is: 9db or a gain coefficient of 0.1259.

Translating this calculation from log space to linear yields the formula:

$$\text{Gain} = (\text{level}/\text{threshold})^{1/\text{ratio}} * (\text{threshold}/\text{level})$$

- **State Transitions:** In addition to calculating the new gain for the compressor, the gain calculation block will also select the filter coefficient for the attack/release filter. The rules for selecting the coefficient are as follows:

In the compression region:

- If the gain calculated is less than the last gain calculated (more compression is being applied), then the filter coefficient is the compressor attack.
- If the gain calculated is more than the last gain calculated (less compression), the filter coefficient is the compressor release.

In the linear region:

- Modify gain until a gain of 1.0 is obtained, using the compressor release.

3. **Attack/Release filter:** In order to prevent objectionable artifacts, the gain is smoothly ramped from the current value to the new value calculated by the gain calculation block. This is achieved using a simple tracking lowpass filter to smooth out the abrupt transitions.

3.5.2. Multi band Compressor Registers

3.6. Limiter/Compressor/Expander

Figure 10. Gain Compressor, Output vs Input

3.6.1. Overview

The Limiter function will limit the output of the DSP module to the DAC modules. If the signal is greater than 0dB it will saturate at 0dB as the final processing step within the DSP module.

Sometimes, the system implementor may wish to provide hearing protection by intentionally limiting the output level before full scale is reached. A limit threshold, independent of the compressor threshold is provided for this purpose. It is expected that the limit threshold is set to a higher level than the compressor threshold.

The traditional compressor algorithm provides two functions simultaneously (depending on signal level). For higher level signals, it can provide a compression function to reduce the signal level. For lower level signals, it can provide an expansion function for either increasing dynamic range or noise gating.

The compressor monitors the signal level and, if the signal is higher than a threshold, will reduce the gain by a programmed ratio to restrict the dynamic range. Limiting is an extreme example of the compressor where, as the input signal level is increased, the gain is decreased to maintain a specific output level.

In addition to limiting the bandwidth of the compressed audio, it is common for compressed audio to also compress the dynamic range of the audio. The expansion function in TSCS25xx can help restore the original dynamics to the audio.

The expander is a close relative of the compressor. Rather than using signal dependent gain to restrict the dynamic range, the expander uses signal dependent gain to expand the dynamic range. Thus if a signal level is below a particular threshold, the expander will reduce the gain even further to extend the dynamic range of the material.

3.6.2. Configuration

This compressor limiter provides the following configurable parameters.

- Compressor/limiter
 - Threshold – The threshold above which the compressor will reduce the dynamic range of the audio in the compression region.
 - Ratio – The ratio between the input dynamic range and the output dynamic range. For example, a ratio of 3 will reduce an input dynamic range of 9db to 3db.
 - Attack Time – The amount of time that changes in gain are smoothed over during the attack phase of the compressor.
 - Release Time – The amount of time that changes in gain are smoothed over during the release phase of the compressor.
 - Makeup gain – Used to increase the overall level of the compressed audio.
- Expander
 - Threshold – The threshold below which the expander will increase the dynamic range of the audio.
 - Ratio – The ratio between the input dynamic range and the output dynamic range of the audio in the expansion range. For example a ratio of 3 will take an input dynamic range of 9db and expand it to 27db.
 - Attack Time – The amount of time that changes in gain are smoothed over during the attack phase of the expander
 - Release Time
 - The amount of time that changes in gain are smoothed over during the release phase of the expander.
- Two level detection algorithms
 - RMS – Use an RMS measurement for the level.
 - Peak – Use a peak measurement for the level.

3.6.3. Controlling parameters

In order to control this processing, there are a number of configurable parameters. The parameters and their ranges are:

- Compressor/limiter
 - Threshold – -40db to 0db relative to full scale.
 - Ratio – 1 to 20
 - Attack Time – typically 0 to 500ms
 - Release Time – typically 25ms to 2 seconds
 - Makeup gain – 0 to 40db
- Expander
 - Threshold – -30 to -60 dB
 - Ratio – 1 to 6
 - Attack Time – same as above
 - Release Time – same as above.
- Two level detection algorithms
 - RMS
 - Peak

3.7. Output Effects

The TSCS25xx offers Bass enhancement, Treble enhancement, Stereo Depth enhancement. The output effects processing is outlined in the following sections.

3.7.1. FX Control Register

Register Address	Bit	Label	Type	Default	Description
R57 (39h) FXCTL	7:5	RSVD	R	000	Reserved

	1	BEEN	RW	0	Bass Enhancement Enable 0 = Disabled 1 = Enabled
	0	BNLFBYP	RW	0	Bass Non-linear Function Bypass: 0 = Enabled 1 = Bypassed

Table 63. FXCTL Register

3.7.2. Stereo Depth (3-D) Enhancement

The TSCS25xx has a digital depth enhancement option to artificially increase the separation between the left and right channels, by enabling the attenuation of the content common to both channels. The amount of attenuation is programmable within a range. The input is prescaled (fixed) before summation to prevent saturation.

The 3-D enhancement algorithm is a tried and true algorithm that uses two principles.

- 1 If the material common to the two channels is removed, then the output will sound more 3-D.
- 2 If the material for the opposite channel is presented to the current channel inverted, it will tend to cancel any material from the opposite channel on the current ear. For example, if the material from the right is presented to the left ear inverted, it will cancel some of the material from the right ear that is leaking into the right ear.

Figure 11. 3-D Channel Inversion

Note: .3D_Mix specifies the amount of the common signal that is added from the left and right channels. This number is a fractional amount between -1 and 1. For proper operation, this value is typically negative.

3.7.3. Psychoacoustic Bass Enhancement

One of the primary audio quality issues with small speaker systems is their inability to reproduce significant amounts of energy in the bass region (below 200Hz). While there is no magic mechanism to make a speaker reproduce frequencies that it is not capable of, there are mechanisms for fooling the ear into thinking that the bass material is being heard.

The psychoacoustic bass processor relies on a psychoacoustic principle called “missing fundamental”. If the human ear hears a proper series of harmonics for a particular bass note, the listener will hear the fundamental of that series, even if it is not present.

A processing algorithm using this principle allows for improving the apparent low frequency response of an audio system below what it is actually capable of. Below is a diagram of the implementation of this algorithm.

Figure 12. Bass Enhancement

3.7.4. Treble Enhancement

One of the mechanisms used to limit the bit rate for compressed audio is to first remove high frequency information before compression. When these files are decompressed, this can lead to dull sounding audio. The TSI treble enhancement replaces these lost high frequencies.

The enhanced treble function works much like the enhanced bass, however it's intended use is different. The Enhanced treble uses a non linear function to add treble harmonics to a signal that has limited high-frequency bandwidth (such as a low bit rate MP3). In this case, the algorithm makes use of the audio fact that presence of audio between 4-8K is a good predictor of audio between 10K-20K.

Figure 13. Treble Enhancement

The enhanced treble NLF has a different set of requirements than the psychoacoustic bass. In particular, the presence of odd high frequency harmonics is objectionable. Thus the most promising NLF for enhanced treble is a half wave rectifier.

3.8. Mute and De-Emphasis

The TSCS25xx has a Soft Mute function, which is used to gradually attenuate the digital signal volume to zero. The gain returns to its previous setting if the soft mute is removed. At startup, the codec is muted by default; to enable audio play, the mute bit must be cleared to 0.

After the equalization filters, de-emphasis may be performed on the audio data to compensate for pre-emphasis that may be included in the audio stream. De-emphasis filtering is only available for 48kHz, 44.1kHz, and 32kHz sample rates.

3.9. Mono Operation and Phase Inversion

Normal stereo operation converts left and right channel digital audio data to analog in separate DACs. However, it is also possible to have the same signal (left or right) appear on both analog output channels by disabling one channel; alternately, there is a mono-mix mode that mixes the two channels digitally before converting to analog using only one DAC. In this mode, the other DAC is switched off, and the resulting mixed stream signal can appear on both analog output channels.

The DAC output defaults to non-inverted. Setting DACPOLL and DACPOLR bits will invert the DAC output phase on the left and right channels.

3.9.1. DAC Control Register

Register Address	Bit	Label	Type	Default	Description
R24 (18h) CNVRTR1	7	DACPOLR	RW	0	Invert DAC Right signal
	6	DACPOLL	RW	0	Invert DAC Left signal
	5:4	DMONOMIX [1:0]	RW	00	DAC mono mix 00: stereo 01: mono ((L/2)+(R/2)) into DACL, '0' into DACR 10: mono ((L/2)+(R/2)) into DACR, '0' into DACL 11: mono ((L/2)+(R/2)) into DACL and DACR
	3	DACMU	RW	1	Digital Soft Mute 1 = mute 0 = no mute (signal active)
	2	DEEMP	RW	0	De-emphasis Enable 1 = Enabled 0 = Disable
	1:0	DACDITH	RW	00	DAC Dither Mode: 0 = Dynamic, half amplitude 1 = Dynamic, full amplitude 2 = DAC dither disabled 3 = Static

Table 64. CNVRTR1 Register

3.10. Analog LoopBack

The TSCS25x allows a Loopback mode that will allow a direct connection from the capture path to the playback path. It provides an internal A-D-A path within the codec, eliminating the need for and external connections to loop the capture data back to the codec. When set, the ADC capture path is sent back directly to the DAC playback path, and the I2S DIN and DOUT signals are not used. This also allows for the Audio Output Processing in the DSP Engine to be applied to the capture data.

To use this mode, the codec has to be configured properly:

- 1) The DAC and ADC configurations must match – they must use a common BCLK and be configured for the same sample rate and bit density.
- 2) The Loopback bit must be enabled.

Playback performance may be reduced in this mode due to the use of the ADC to convert the input before processing through the DAC and DSP Engine.

3.10.1. Analog LoopBack Registers

Register Address	Bit	Label	Type	Default	Description
R105(69h) DTEST	7:6	RSVD	0	0	Reserved

3.11. Analog Outputs

3.11.1. Headphone Output

The HPOut pins can drive a 16Ohm or 32Ohm headphone or alternately drive a line output. The signal volume of the headphone amplifier can be independently adjusted under software control by writing to HPVOL_L and HPVOL_R. Setting the volume to 0000000 will mute the output driver; the output remains at ground, so that no click noise is produced when muting or un-muting.

Gains above 0dB run the risk of clipping large signals.

To minimize artifacts such as clicks and zipper noise, the headphone outputs feature a volume fade function that smoothly changes volume from the current value to the target value.

3.11.2. Headphone Volume Control Registers

Register Address	Bit	Label	Type	Default	Description
R0 (00h) HPVOLL	7	RSVD	R	0	Reserved

4. INPUT AUDIO PROCESSING

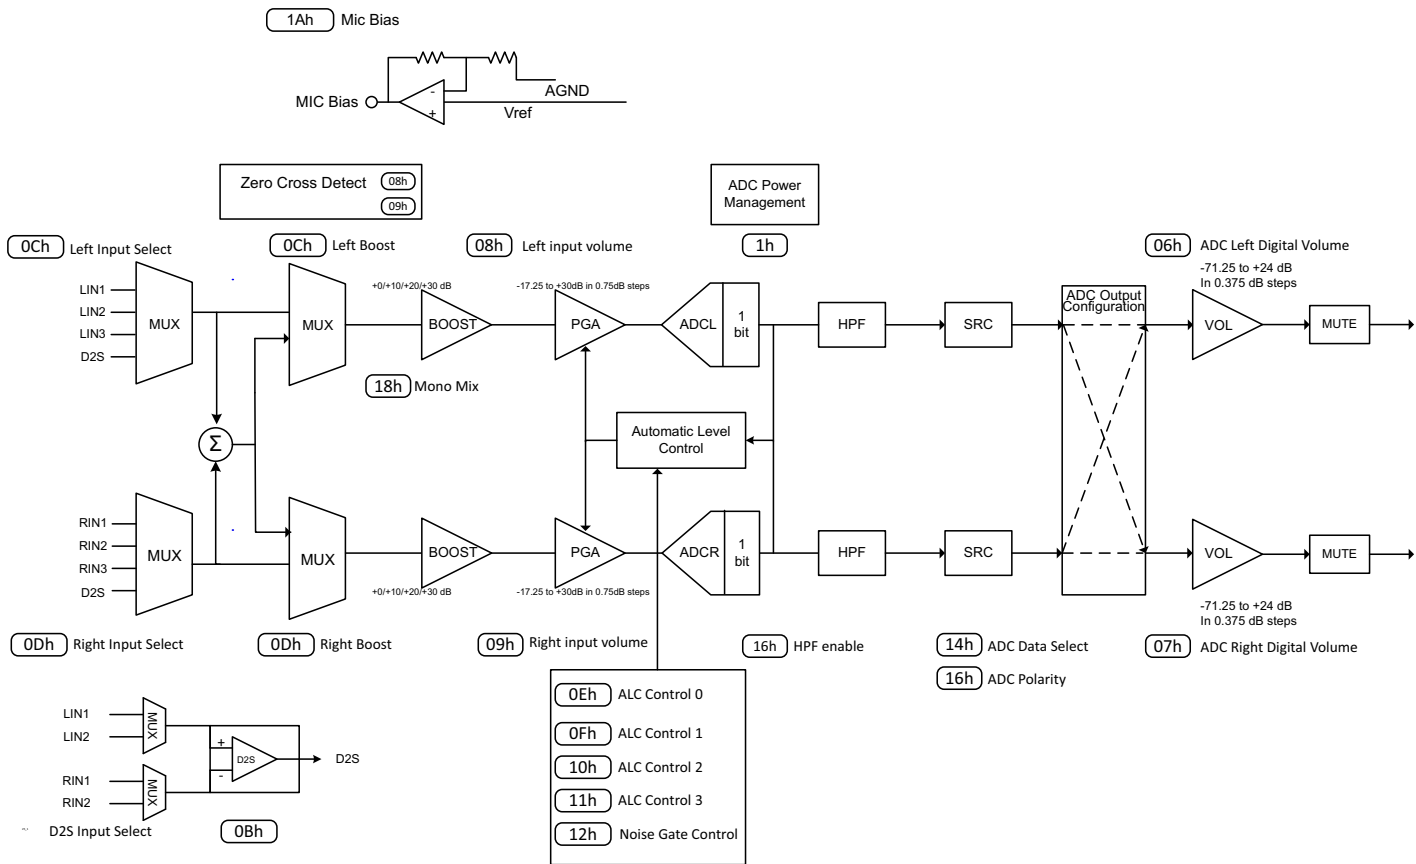

Figure 14. Input Audio Processing

4.1. Analog Inputs

The TSCS25xx provides multiple high impedance, low capacitance AC-coupled analog inputs with an input signal path to the stereo ADCs. Prior to the ADC, there is a multiplexor that allows the system to select which input is in use. Following the mux, there is a programmable gain amplifier and also an optional microphone gain boost. The gain of the PGA can be controlled either by the system, or by the on-chip level control function. The stereo record path can also operate with the two channels mixed to mono either in the analog or digital domains.

Signal inputs are biased internally to AVSS but AC coupling capacitors are required when connecting microphones (due to the 2.5V microphone bias) or when offsets would cause unacceptable “zipper noise” or pops when changing PGA or boost gain settings. To avoid audio artifacts, the line inputs are kept biased to analog ground when they are muted or the device is placed into standby mode.

4.1.1. Input Software Control Register

Register Address	Bit	Label	Type	Default	Description

	3:0	RSVD	R	0000	Reserved

Table 67. INSELL and INSLR Register

4.2. Mono Mixing and Output Configuration

The stereo ADC can operate as a stereo or mono device, or the two channels can be mixed to mono. Mixing can occur either in the input path (analog, before ADC) or after the ADC. MONOMIX determines whether to mix to mono, and where.

For analog mono mix, either the left or right channel ADC can be used for the audio stream. The other ADC may be powered off to conserve power. A differential input amplifier may be selected as a mono source to either ADC input. This D2S amplifier can select either Input 1 or Input 2 using the DS bit.

The system also has the flexibility to select the data output. ADCDSEL configures the interface, assigning the source of the left and right ADC independently.

4.3. Microphone Bias

The MICBIAS output is used to bias electric type microphones. It provides a low noise reference voltage used for an external resistor biasing network. The MICB control bit is used to enable the output.

The MICBIAS can source up to 3mA of current; therefore, the external resistors must be large enough to conform to this limit.

4.3.1. Microphone Bias Control Bit

Table 71. Mic Bias Enable

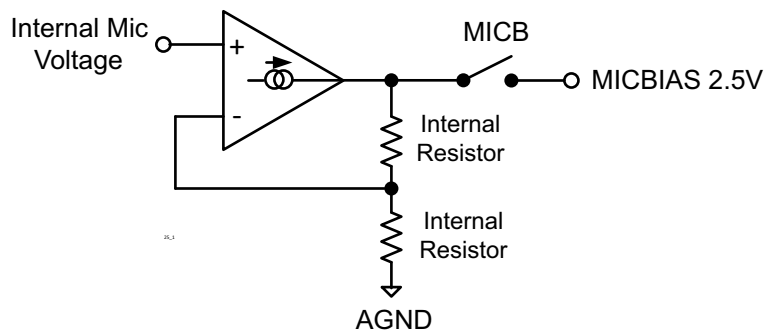

Figure 15. Mic Bias

4.4. Programmable Gain Control

The Programmable Gain Amplifier (PGA) enables the input signal level to be matched to the ADC input range. Amplifier gain is adjustable across the range +30dB to -17.25dB (using 0.75dB steps). The PGA can be controlled directly by the system software using the Input Volume Control registers (INVOLL and INVOLR), or alternately the Automatic Level Control (ALC) function can automatically control the gain. If the ALC function is used, writing to the Input Volume Control registers has no effect.

Left and right input gains are independently adjustable. By controlling the update bit INVOLU in R10 the left and right gain settings can be simultaneously updated. To eliminate zipper noise, LZCEN and RZCEN bits enable a zero-cross detector to insure changes only occur when the signal is at zero. A time-out for zero-cross is also provided, using TOEN in register R28 (1Dh).

4.4.1. Input PGA Software Control Register

Register Address	Bit	Label	Type	Default	Description

Table 72. INVOLL/ INVOLR Register

4.5. ADC Digital Filter

To provide the correct sampling frequency on the digital audio outputs, ADC filters perform true 24-bit signal processing and convert the raw multi-bit oversampled data from the ADC using the digital filter path illustrated below.

Figure 16. ADC Filter Data Path

TSCS25xx

Portable Consumer CODECs

The ADC digital filters contain a software-selectable digital high pass filter. When the high-pass filter is enabled, the dc offset is continuously calculated and subtracted from the input signal. The HPOR bit enables the last calculated DC offset value to be stored when the high-pass filter is disabled; this value will then continue to be subtracted from the input signal. To provide support for calibration, the stored and subtracted value will not change unless the high-pass filter is enabled even if the DC value is changed. The high pass filter may be enabled separately for each of the left and right channels.

The output data format can be programmed by the system. This allows stereo or mono recording streams at both inputs. Software can change the polarity of the output signal.

4.5.1. ADC Signal Path Control Register

Register Address	Bit	Label	Type	Default	Description
R22 (16h) CNVRTR0	7	ADCPOLR	RW	0	0 = Right polarity not inverted 1 = Right polarity inverted

1	0	High-pass filter enabled on left channel, disabled on right channel
1	1	High-pass filter disabled on left and right channels

Table 74. ADC HPF Enable

4.6. Digital ADC Volume Control

The ADC volume can be controlled digitally, across a gain and attenuation range of -71.25dB to +24dB (0.375dB steps). The level of attenuation is specified by an eight-bit code 'ADCVOL_x', where 'x' is L, or R. The value "00000000" indicates mute; other values describe the number of 0.375dB steps above -71.25dB.

The ADCVOLUME bit controls the updating of digital volume control data. When ADCVOLUME is written as '0', the ADC digital volume is immediately updated with the ADCVOL_L data when the Left ADC Digital Volume register is written. When ADCVOLUME is set to '1', the ADCVOL_L data is held in an internal holding register until the Right ADC Digital Volume Register is written.

4.6.1. ADC Digital Volume Control Register

Register Address	Bit	Label	Type	Default	Description
R6 (06h) ADCVOLL	7:0	ADCVOL_L [7:0]	RW	10111111 (0dB)	Left ADC Digital Volume Control 0000 0000 = Digital Mute 0000 0001 = -71.25dB 0000 0010 = -70.875dB ... 0.375dB steps up to 1111 1111 = +24dB Note: If ADCVOLUME is set, this setting will take effect after the next write to the Right Input Volume register.
R7 (07h) ADCVOLR	7:0	ADCVOL_R [7:0]	RW	10111111 (0dB)	Right ADC Digital Volume Control 0000 0000 = Digital Mute 0000 0001 = -71.25dB 0000 0010 = -70.875dB ... 0.375dB steps up to 1111 1111 = +24dB

Table 75. ADCVOLL/ADCVOLR Register

4.7. Automatic Level Control (ALC)

The TSCS25xx has an automatic level control to achieve constant recording volume across a range of input signal levels. The device uses a digital peak detector to monitor and adjusts the PGA gain to provide a constant signal level at the ADC input. A range of adjustment between -6dB and -28.5dB (relative to ADC full scale) can be selected. The device provides programmable attack, hold, and decay times to smooth adjustments. The level control also features a peak limiter to prevent clipping when the ADC input exceeds a threshold. Note that if the ALC is enabled, the input volume controls are ignored.

4.7.1. ALC Operation

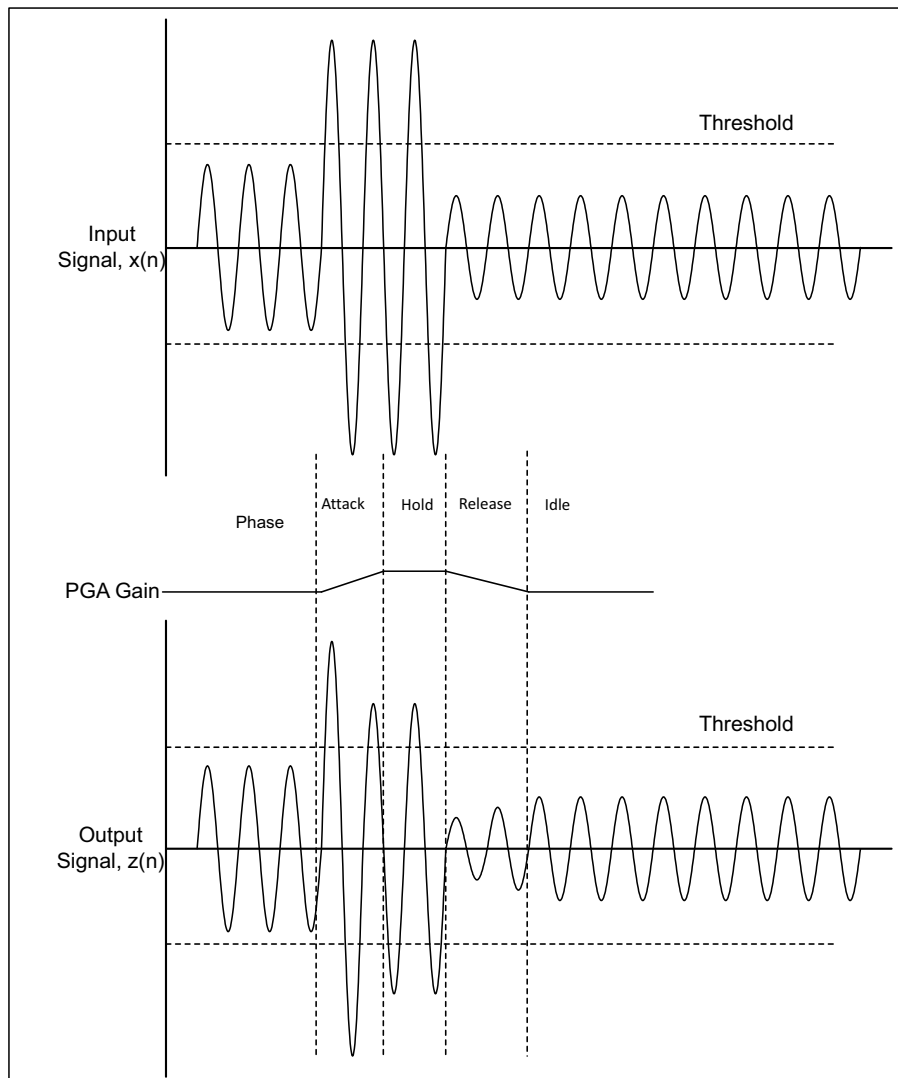

Figure 17. ALC Operation

When ALC is enabled, the recording volume target can be programmed between -6dB and -28.5dB (relative to ADC full scale). The ALC will attempt to keep the ADC input level to within $\pm 0.5\text{dB}$ of the target level. An upper limit for the PGA gain can also be imposed, using the MAXGAIN control bits.

Hold time specifies the delay between detecting a peak level being below target, and the PGA gain beginning to ramp up. It is specified as $2^n \times 2.67\text{mS}$, enabling a range between 0mS and over 40s ; ramp-down begins immediately if the signal level is above the target.

Decay (Gain Ramp-Up) Time is the time that it takes for the PGA to ramp up across 90% of its range. The time is $2^n \times 24\text{mS}$. The time required for the recording level to return to its target value therefore depends on the decay time and on the gain adjustment required.

Attack (Gain Ramp-Down) Time is the time that it takes for the PGA to ramp down across 90% of its range. Time is specified as $2^n \times 24\text{mS}$. The time required for the recording level to return to its target value depends on both the attack time and on the gain adjustment required.

When operating in stereo, the peak detector takes the maximum of left and right channel peak values, and both PGAs use the same gain setting, to preserve the stereo image. If the ALC function is only enabled on one channel, only one PGA is controlled by the ALC mechanism, and the other channel runs independently using the PGA gain set through the control registers.

If one ADC channel is unused, the peak detector will ignore that channel.

The ALC function can operate when the two ADC outputs are mixed to mono in the digital domain or in the analog domain.

4.7.2. ALC Control Register

Register Address	Bit	Label	Type	Default	Description

Table 76. ALC0/1/2/3 Registers

4.7.3. Peak Limiter

To prevent clipping, the ALC circuit also includes a limiter function. If the ADC input signal exceeds 87.5% of full scale (−1.16dB), the PGA gain is ramped down at the maximum attack rate, until the signal level falls below 87.5% of full scale. This function is automatically enabled whenever the ALC is enabled.

4.7.4. Input Threshold

To avoid hissing during quiet periods, the TSCS25xx has an input threshold noise gate function that compares the signal level at the inputs to a noise gate threshold. Below the threshold, the programmable gain can be held , or the ADC output can be muted. The threshold can be adjusted in increments of 1.5dB.

The noise gate activates when the signal-level at the input pin is less than the Noise Gate Threshold (NGTH) setting.

The ADC output can be muted. Alternatively, the PGA gain can be held .

The threshold is adjusted in 1.5dB steps. The noise gate only works in conjunction with the ALC, and always operates on the same channel(s) as the ALC.

4.7.5. Noise Gate Control Register

Register Address	Bit	Label	Type	Default	Description
R12 (12h) NGATE	7:3	NGTH [4:0]	RW	00000	Noise gate threshold (compared to ADC full-scale range) 00000 -76.5dBfs 00001 -75dBfs ... 1.5 dB steps 11110 -31.5dBfs 11111 -30dBfs

Table 77. NGATE Register

5. DIGITAL AUDIO AND CONTROL INTERFACES

5.1. Data Interface

For digital audio data, the TSCS25xx uses six pins to input and output digital audio data.

- ADCDOUT: ADC data output
- ADCLRCLK: ADC data alignment clock
- ADCBCLK: Bit clock, for synchronization
- DACDIN: DAC data input
- DACLRCLK: DAC data alignment clock
- DACBCLK: Bit clock, for synchronization

The clock signals ADCBCLK, ADCLRCLK, DACBCLK, and DACLRCLK are outputs when the TSCS25xx operates as a master; they are inputs when it is a slave. Four different data formats are supported:

- Left-justified for Linear PCM
- Right-justified for Linear PCM
- I²S for Linear PCM
- Bluetooth PCM

All of these format are MSB first.

5.2. Master and Slave Mode Operation

The TSCS25xx can be used as either a master or slave device, selected by the MS Bit. When operating as a master, the TSCS25xx generates ADCBCLK, ADCLRCLK, DACBCLK and DACLRCLK and controls sequencing of the data transfer the data pins. In slave mode, the TSCS25xx provides data aligned to clocks it receives.

Figure 18. Master mode

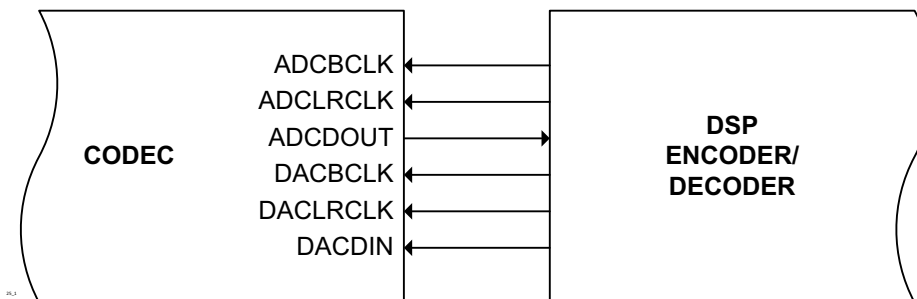

Figure 19. Slave mode

5.3. Audio Data Formats

The TSCS25xx supports 4 common audio interface formats and programmable clocking that provides broad compatibility with DSPs, Consumer Audio and Video SOCs, FPGAs, handset chipsets, and many other products.

In all modes, depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles before each LRCLK transition. If the converter word length is smaller than the number of clocks per sample in the frame then the DAC will ignore (truncate) the extra bits while the ADC will zero pad the output data. If the converter word length chosen is larger than the number of clocks available per sample in the frame, the ADC data will be truncated to fit the frame and the DAC data will be zero padded.

5.3.1. Bluetooth PCM Interface

Bluetooth PCM is a time-division multiplexed format. The Bluetooth PCM interface operates in either a slave or master mode. Data is sampled on the falling edge of the bit clock and transmitted on the rising edge. A control bit selects between a delayed and non-delayed data timing relative to the start of the frame sync. The LRCLK is one bit clock long for a Short Frame Sync and one slot wide for a Long Frame Sync. Bluetooth PCM mode supports both mono and stereo formats.

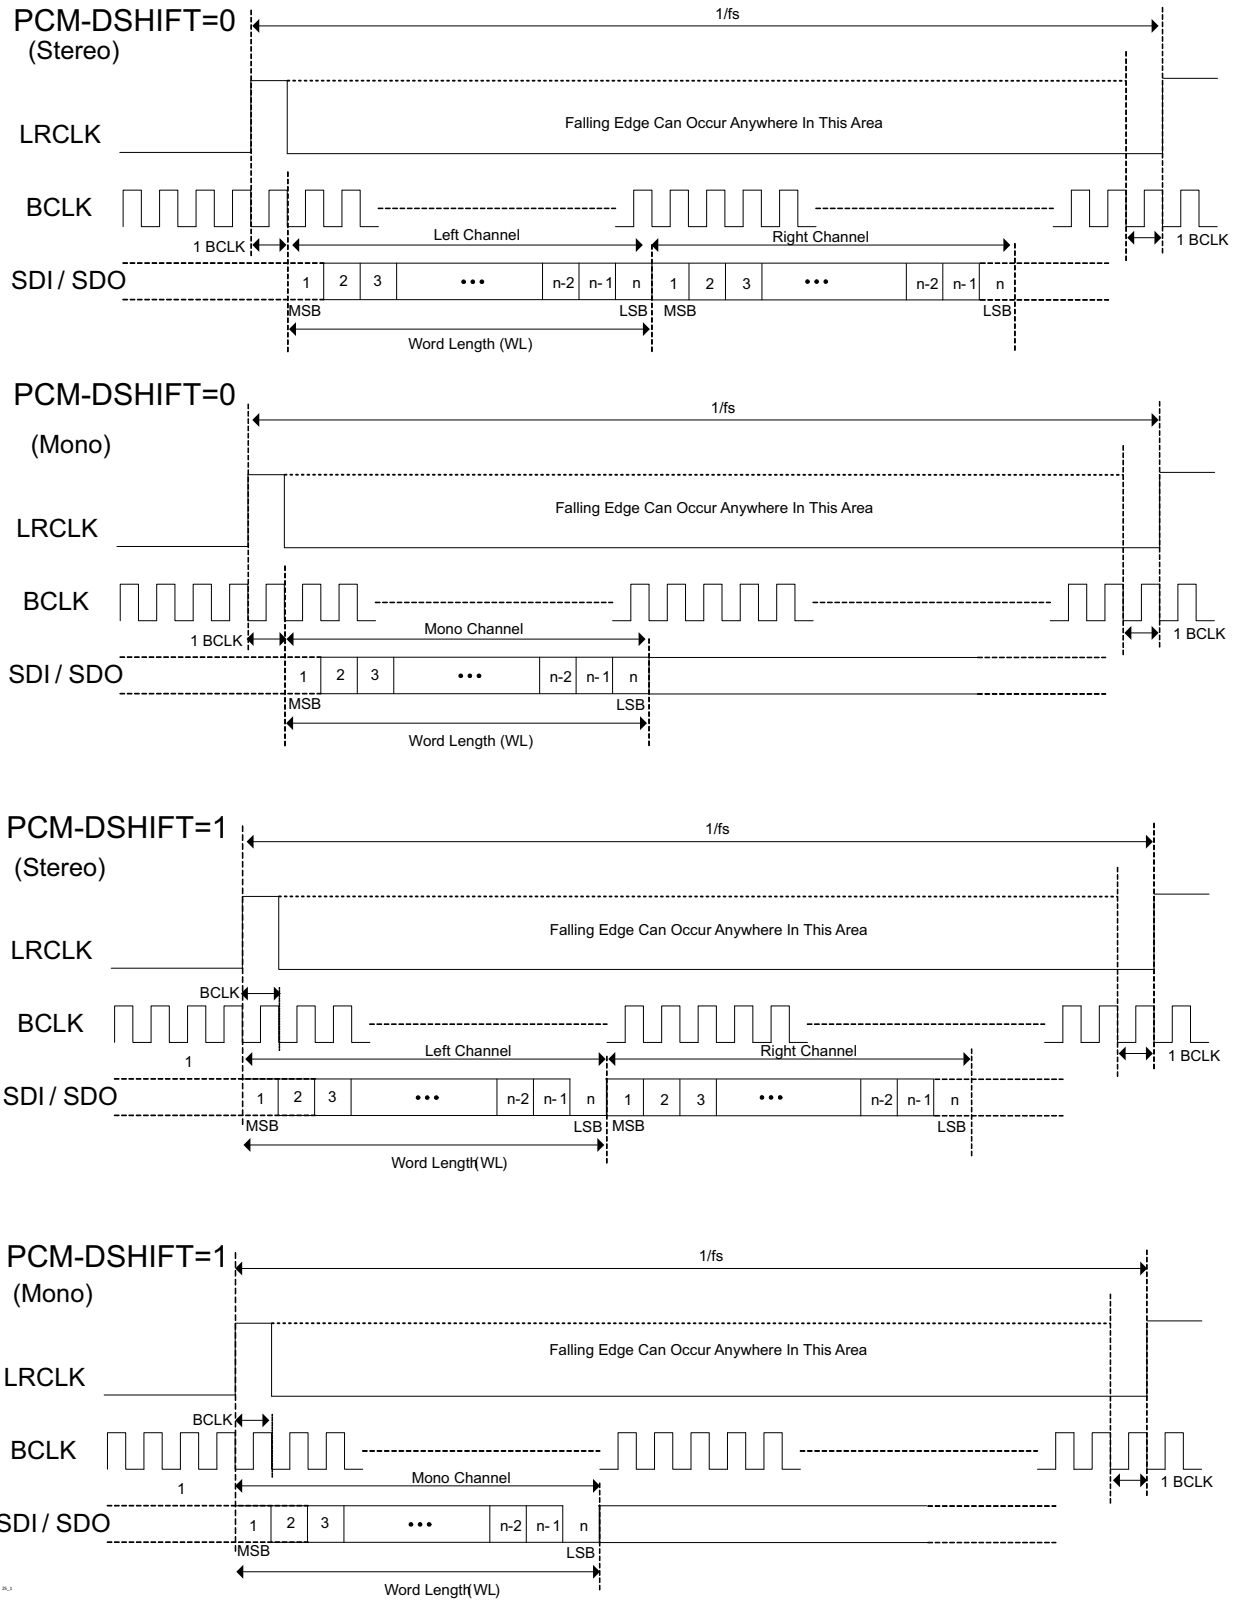

Figure 20. Bluetooth PCM Audio Interface

For digital audio data, the TSCS25xx uses below six pins for PCM audio interface.

- ADCDOUT: PCM data out
- ADCCLRCLK: ADC PCM data alignment
- ADCBCLK: ADC PCM Bit clock, for synchronization
- DACDIN: PCM data in
- DACLRCLK: DAC PCM data alignment
- DACBCLK: DAC PCM Bit clock, for synchronization

Table 83. AIC2 Register

5.4.3. Bit Clock and LR Clock Mode Controls

Although the DAC and ADC interfaces implement separate Bit Clock and LR Clock pins, it is also possible to share one or both of the clocks.

the following restrictions must be observed when the BCLK from one path (DAC or ADC) is combined with the LRCLK from the other path (ADC or DAC) as described by the Bit Clock and LR Clock Mode Selection table below:

1. Both the DAC and ADC must be programmed for the same sample rate
2. Both the DAC and ADC must be programmed for the same number of clocks per frame
3. When in slave mode, the DAC and ADC data must be aligned relative to the provided BCLK and LRCLK (this is guaranteed in master mode)
4. The DAC and ADC must be powered down when changing the BLRCM mode
5. If sharing the BCLK from one path (DAC or ADC) and the LRCLK from the other path (ADC or DAC), shut down both the DAC and ADC before programming the sample rate and clocks per frame for either. (Again, both must match.)

MS	BLRCM [2:0]	MODE ¹	DAC BCLK	ADC BCLK	DAC LRCLK	ADC LRCLK
0	000	Independent	Input for playback path	input for record path	Input for playback path	input for record path

Table 86. AIC3 Register

5.4.6. Bit Clock Mode

The default master mode bit clock generator automatically produces a bit clock frequency based on the sample rate and word length. When enabled by setting the appropriate BCM bits, the bit clock mode (BCM) function overrides the default master mode bit clock generator to produce the bit clock frequency shown below: Note that selecting a word length of 24-bits in Auto mode generates 64 clocks per frame (64fs)

Register Address	Bit	Label	Type	Default	Description
R23/R25 (17h/19h) ADCSR/DACSR	7:6	ABCM[1:0] DBCM[1:0]	RW	00	BCLK Frequency 00 = Auto 01 = 32 x fs 10 = 40 x fs 11 = 64 x fs

Table 87. ADCSR/ DACSR Register

The BCM mode bit clock generator produces 16, 20, or 32 bit cycles per sample.

Figure 24. Bit Clock mode

Note: The clock cycles are evenly distributed throughout the frame (true multiple of LRCLK not a gated clock.)

5.5. I2C /Control Interface

The registers are accessed through a serial control interface using a multi-word protocol comprised of 8-bit words. The first 8 bits provide the device address and Read/Write flag. In a write cycle, the next 8 bits provide the register address; all subsequent words contain the data, corresponding to the 8 bits in each control register. The control interface operates using a standard 2-wire interface, as a slave device only. The TSCS25xx has 8 bit device address for E2.

5.5.1. Register Write Cycle

The controller indicates the start of data transfer with a high to low transition on SDA while SCL remains high, signalling that a device address and data will follow. All devices on the 2-wire bus respond to the start condition and shift in the next eight bits on SDIN (7-bit address + Read/Write bit, MSB first). If the device address received matches the address of the TSCS25xx and the R/W bit is '0', indicating a write, then the TSCS25xx responds by pulling SDA low on the next clock pulse (ACK); otherwise, the TSCS25xx returns to the idle condition to wait for a new start condition and valid address.

Once the TSCS25xx has acknowledged a correct device address, the controller sends the TSCS25xx register address. The TSCS25xx acknowledges the register address by pulling SDA low for one clock pulse (ACK). The controller then sends a byte of data (B7 to B0), and the TSCS25xx acknowledges again by pulling SDA low.

When there is a low to high transition on SDA while SCL is high, the transfer is complete. After receiving a complete address and data sequence the TSCS25xx returns to the idle state. If a start or stop condition is detected out of sequence, the device returns to the idle condition.

Figure 25. 2-Wire Serial Control Interface

5.5.2. Multiple Write Cycle

The controller may write more than one register within a single write cycle. To write additional registers, the controller will not generate a stop or start (repeated start) command after receiving the acknowledge for the second byte of information (register address and data). Instead the controller will continue to send bytes of data. After each byte of data is received, the register address is incremented.

Figure 26. Multiple Write Cycle

5.5.3. Register Read Cycle

The controller indicates the start of data transfer with a high to low transition on SDA while SCL remains high, signalling that a device address and data will follow. If the device address received matches the address of the TSCS25xx and the R/W bit is '0', indicating a write, then the TSCS25xx responds by pulling SDA low on the next clock pulse (ACK); otherwise, the TSCS25xx returns to the idle condition to wait for a new start condition and valid address.

Once the TSCS25xx has acknowledged a correct address, the controller sends a restart command (high to low transition on SDA while SCL remains high). The controller then re-sends the devices address with the R/W bit set to '1' to indicate a read cycle. The TSCS25xx acknowledges by pulling SDA low for one clock pulse. The controller then receives a byte of register data (B7 to B0).

For a single byte transfer, the host controller will not acknowledge (high on data line) the data byte and generate a low to high transition on SDA while SCL is high, completing the transfer. If a start or stop condition is detected out of sequence, the device returns to the idle condition.

Figure 27. Read Cycle

5.5.4. Multiple Read Cycle

The controller may read more than one register within a single read cycle. To read additional registers, the controller will not generate a stop or start (repeated start) command after sending the acknowledge for the byte of data. Instead the controller will continue to provide clocks and acknowledge after each byte of received data. The codec will automatically increment the internal register address after each register has had its data successfully read (ACK from host) but will not increment the register address if the data is not received correctly by the host (nACK from host) or if the bus cycle is terminated unexpectedly (however the EQ/Filter address will be incremented even if the register address is not incremented when performing EQ/Filter RAM reads). By automatically incrementing the internal register address after each byte is read, all the internal registers of the codec may be read in a single read cycle.

Figure 28. Multiple Read Cycle

5.5.5. Device Addressing and Identification

The TSCS25xx has a default slave address of E2. However, it is sometimes necessary to use a different address. The TSCS25xx has a device address register for this purpose. The part itself has an 8-bit Identification register and an 8-bit revision register that provide device specific information for software. In addition, an 8-bit programmable subsystem ID register can allow firmware to provide a descriptive code to higher level software such as an operating system driver or application software.

5.5.5.1. Device Address Register

Register Address	Bit	Label	Type	Default	Description
R124 (7Ch) DEVADR	7:1	ADDR[7:1]	RW	1110001	7-bit slave address
	0	RSVD	R	0

Register Address	Bit	Label	Type	Default	Description
R127 (7Fh) REVID	7:4	MAJ[3:0]	R	xh	4-bit major revision number. Contact TSI.
	3:0	MNR[3:0]	R	xh	4-bit minor revision number. Contact TSI.

Table 90. REVID Register

5.5.7. Register Reset

The TSCS25xx registers may be reset to their default values using the reset register. Writing a special, non-zero value to this register causes all other registers to assume their default states. Device status bits will not necessarily change their values depending on the state of the device.

Register Address	Bit	Label	Type	Default	Description
R128 (80h) RESET	7:0	Reset[7:0]	RW	00h	Reset register Writing a value of 85h will cause registers to assume their default values. Reading this register returns 00h

Table 91. RESET Register

6. GPIO'S

Two GPIO's are available on the GPIO1-GPIO0 pins. These GPIO pins are accessed via register bits. The general-purpose input/output (GPIO) pins can be used as either inputs or outputs. These pins are readable and can be set or read through the control interface. These pins are useful for interfacing to external hardware.

6.1. GPIO Usage Summary

Table 94. GPIOCTL2 Register

7. CLOCK GENERATION

The TSCS25xx uses two PLL's to generate two high frequency reference clocks. The clock frequencies of each reference clock are based on multiples of 44.1 kHz and 48 kHz sample rates. The clock source for the PLL's can be the MCLK2 pin or one of the I2S interface BCLK inputs. The clock source reference is set in register 8F. Each PLL can be independently powered down if the audio sample rates generated by that particular PLL are not required.

7.1. On-Chip PLLs

The TSCS25xx generates two high-quality, high-frequency clocks 122.880 MHz and 112.896 MHz. The PLL support a wide range of input clock frequencies. Some typical frequencies are 19.2 MHz, 22 MHz, 22.5792 MHz, 24 MHz, 24.576 MHz, 27 MHz, and 36 MHz. It should be noted that some input clock frequencies may not result in being able to generate the 122.880 MHz and 112.896 MHz clocks exactly resulting in an error in the audio sample rate.

Audio Clocks - Each PLL generates one of two clock frequencies based on two audio sample rates.

- 122.880 MHz (2560 x 48 kHz)
- 112.896 MHz (2560 x 44.1 kHz)

It is important that the needed PLLs remain on until all audio functions, including jack detection, are disabled.

The MCLK2 pin is configured to input a high frequency clock from an external oscillator or other external clock source.

Figure 29. PLL Block Diagram

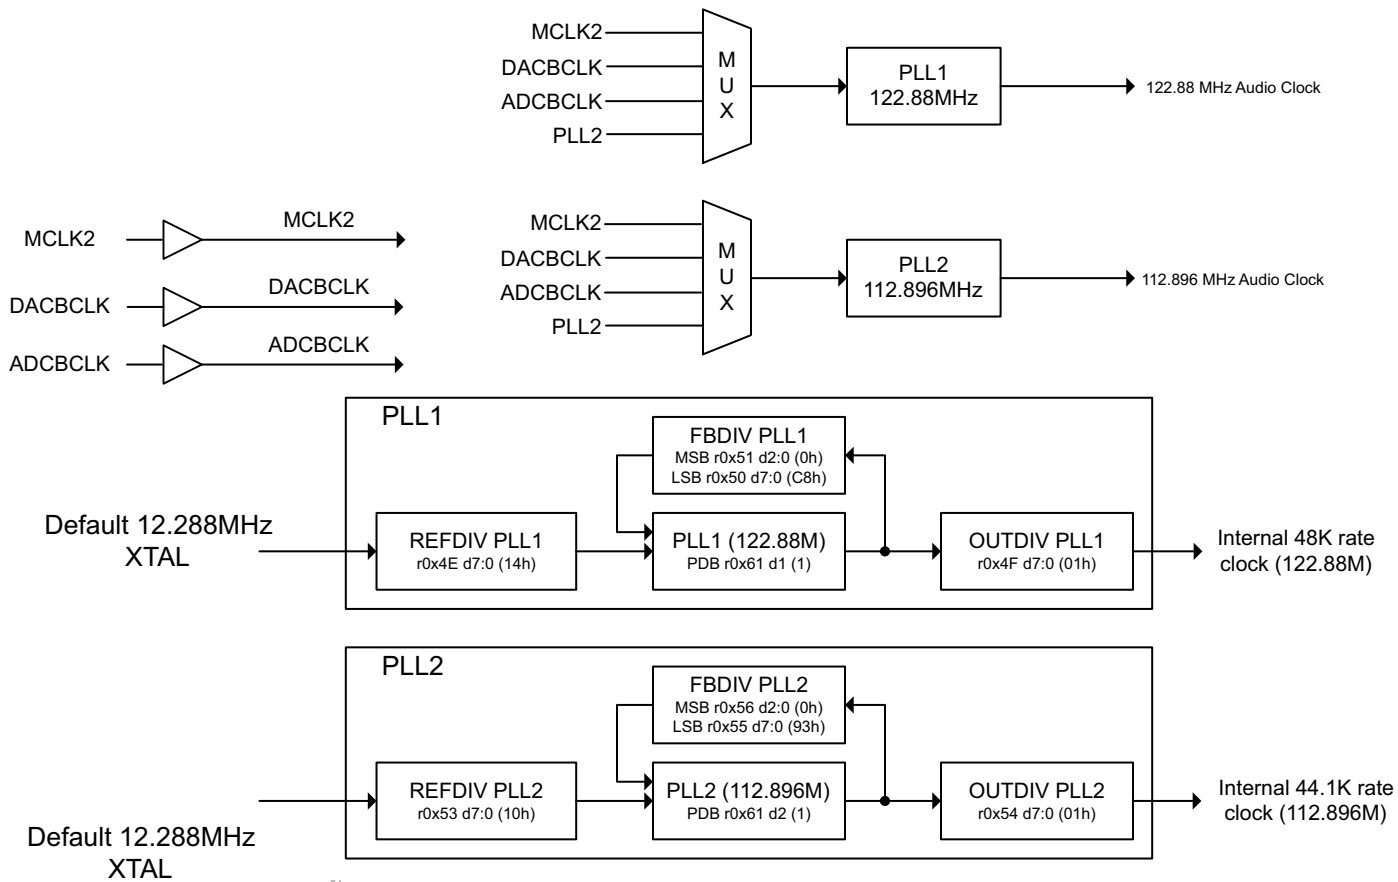

Figure 30. System Clock Diagram

7.2. System Clock Generation

The TSCS25xx supports an internal clock and audio sample rate that is selectable between 11.025 kHz, 12 kHz, 22.050 kHz, 24 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, and 96 kHz. One bi-directional stereo I2S interface is available. In Master mode an internal timing generator is used to specify the audio sample rate. The sample rate specified in Master mode is independent from the internal clock rate and the specified range is 8 kHz to 96 kHz. A variety of sample rates based on 44.1 kHz, 48 kHz and 32 kHz are supported. A highly programmable PLL enables just about any input frequency to be used.

7.2.1. PLL Dividers

The chosen input frequency is multiplied up by the PLL's to generate the required output frequencies; 122.88 MHz and 112.896 MHz. It should be noted that it may not always be possible to generate the required output frequencies with zero error. Some values for the PLL dividers relative a specific input frequency are shown in the table below.

	0	RESERVED	R	0h	Reserved

Table 109. PLLCTL1C Register

7.2.2. PLL Power Down Control

Each PLL can be powered down to save power if only one set of base audio rates is required. The base audio rates are defined as 44.1kHz based rates or 48kHz based rates. If support for either 44.1 kHz or 48 kHz based rates is not needed then the PLL associated with the unused rate can be powered down.

7.2.3. Audio Clock Generation

Figure 33 shows the simplified block diagram. The TSCS25xx utilizes internal PLLs to generate the PLL clocks at 112.896 MHz (22.5792 *5) and 122.880 MHz (24.576 *5). Intermediate clocks (61.44 MHz, 40.96 MHz, 56.448 MHz) are then generated which are then used to generate the audio sample rates. There is one internal clock rate that can be specified to operate at 11.025 kHz, 12 kHz, 22.050 kHz, 24 kHz, 44.1 kHz, 48 kHz, 88.2 kHz, and 96 kHz. When changing sample rates a delay of up to 5mS may be needed for the part to properly lock PLLs, flush filters, etc.

7.2.3.1. PLL Clock Source

The clock source for the PLL can be selected from the MCLK2 pin or one of the I2S BCLK inputs via a selectable mux.

7.2.3.2. Internal Sample Rate Control Register

These register define the internal sample rate.

Register Address	Bit	Label	Default	Description
R23(17h) ADCSR	7:6	ABCM	0h	ADC bit Clock Mode (for ADCBCLK generation in master mode): 0h=Auto 1h = 32x Fs 2h = 40x Fs 3h = 64x Fs

10	000	61.44 MHz	12 kHz(MCLK/5120)
	001		24 kHz(MCLK/2560)
	010		48 kHz (MCLK/1280)
	011		96 kHz (MCLK/640)

Table 112. DAC/ADC Sample rates

7.2.3.3. MCLK2 Pin

The MCLK2 pin is configured to be an input and can provide a clock to drive the input to the PLLs or the I2S Master Mode clock generators.

7.2.3.4. I2S Master Mode Clock Generation

I2S input audio source can operate as a timing Slave or Master. When operated in Master Mode an internal clock generator is used to produce the required bit and frame clocks to be driven out of the LRCLK and BCLK pins of each input I2S interface. The clock source for the I2S master clock generation can be selected between the PLL generated internal timing or an externally supplied clock via the MCLK2 input.

7.2.3.5. I2S Master Mode Sample Rate Control

I2S slave or master mode is set in register 13 MS bit. The I2S BR bits set the base audio sample to be either 44.1Khz or 48kHz. The I2S BM bits are then used to set the base rate multiplier ratio. The I2S BCM bits set the BCLK ratio vs sample rate. The I2S BR, BM and BCM bits are located in register 17h for the ADC while register 19h for the DAC.

7.2.3.6. DAC/ADC Clock Control

The power consumption and audio quality may be adjusted by changing the converter modulator rate. By default the DAC and ADC Sigma-Delta modulators run at the specified OSR rates for the best audio quality. The modulator rates for the converters may be forced to run at half their nominal OSR rates to conserve power. A third option allows the modulator rate to automatically drop to half rate when low sampling rates are chosen (1/2 or 1/4 the base rate.) The DACs and ADCs are independently controlled

8. CHARACTERISTICS

8.1. Electrical Specifications

8.1.1. Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the TSCS25xx. These ratings, which are standard values for TSI commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.

Item	Maximum Rating
Voltage on any pin relative to Ground	V _{ss} - 0.3V TO V _{dd} + 0.3V
Operating Temperature	0 °C TO 70 °C
Storage Temperature	-55 °C TO +125 °C
Soldering Temperature	260 °C
MICBias Output Current	3mA
Amplifier Maximum Supply Voltage	6 Volts = PVDD
Audio Maximum Supply Voltage	3 Volts = AVDD/CPVDD
Digital I/O Maximum Supply Voltage	3.6 Volts = DVDD_IO
Digital Core Maximum Supply Voltage	2.0 Volts = DVDD

Table 116. Electrical Specification: Maximum Ratings

8.1.2. Recommended Operating Conditions

	PVDD	3.0		5.5	V
Ambient Operating Temperature	Analog - 5 V	0	25	70	°C
Case Temperature	T _{case}			90	°C

Table 117. Recommended Operating Conditions

ESD: The TSCS25xx is an ESD (electrostatic discharge) sensitive device. The human body and test equipment can accumulate and discharge electrostatic charges up to 4000 Volts without detection. Even though the TSCS25xx implements internal ESD protection circuitry, proper ESD precautions should be followed to avoid damaging the functionality or performance.

Note:

- Registers not described in this map should be considered “reserved”.
- Numerous portions of the register map are compatible with popular codecs from other vendors.

10. PIN INFORMATION

10.1. TSCS25A3 Pin Diagram

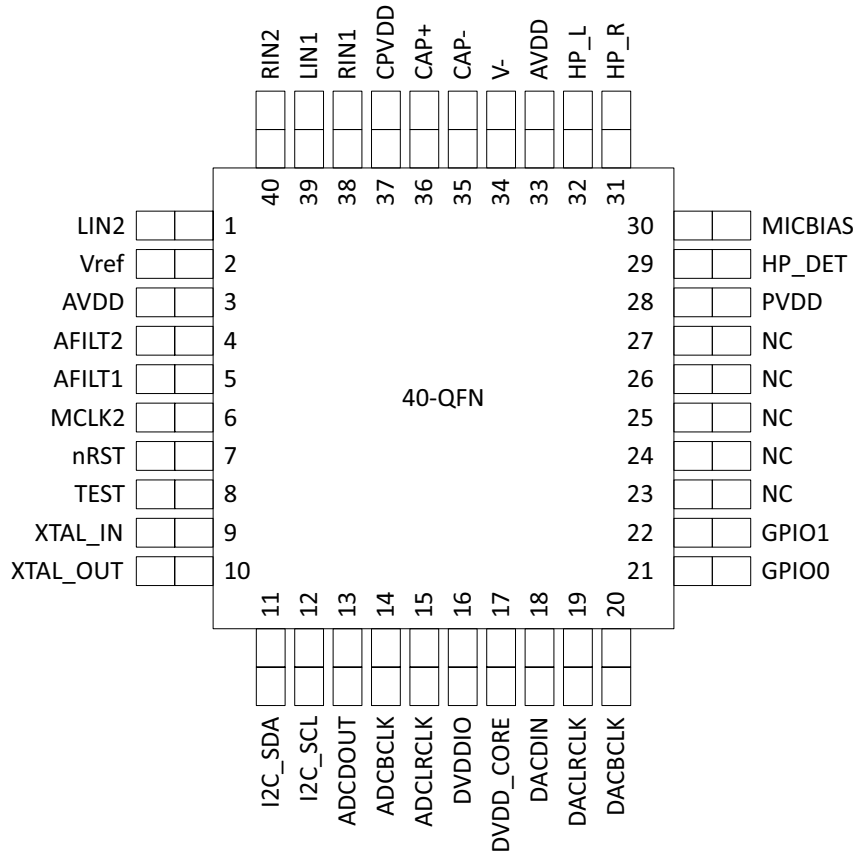

Figure 32. 40QFN Pin Assignment

10.2. Pin Tables

10.2.1. Power Pins

Pin Name	Pin Function	I/O	Internal Pull-up Pull-down	40 pin loc
PVDD	Bias supply	I(Power)	None	28
DVDD_Core	DSP and other core logic+clocks	I(Power)	None	17
DVDDIO	Interface (I ² S, I ² C, GPIO)	I(Power)	None	16
AVDD	Analog core supply	I(Power)	None	3,33
CPVDD	Charge pump supply	I(Power)	None	37
CAP+	Flying cap	I/O(Power)	None	36
CAP-	Flying cap	I/O(Power)	None	35
V-	Negative Analog supply (Bypass cap)	O(Power)	None	34
VSS	DAP		None	

Table 122. Power Pins

Total Pins: 9

10.2.2. Reference Pins

Pin Name	Pin Function	I/O	Internal Pull-up Pull-down	40 Pin loc
MICBIAS	2.5V 1.5 mA microphone bias	O(Analog)	None	30
AFILT1	ADC input filter cap	I(Analog)	None	5
AFILT2	ADC input filter cap	I(Analog)	None	4
Vref	VREF reference pin (bypass)	I(Analog)	None	2

Table 123. Reference Pins

Total Pins: 4

10.2.3. Analog Input Pins

Pin Name	Pin Function	I/O	Internal Pull-up Pull-down	40 Pin loc
LIN1	Left Input #1	I(Analog)	None	39
RIN1	Right Input #1	I(Analog)	None	38
LIN2	Left Input #2	I(Analog)	None	1
RIN2	Right Input #2	I(Analog)	None	40

Table 124. Analog Input Pins

Total Pins: 4

10.2.4. Analog Output Pins

Pin Name	Pin Function	I/O	Internal Pull-up Pull-down	40 Pin loc
HP_L	Headphone output	O(Analog)	None	32
HP_R	Headphone output	O(Analog)	None	31

Table 125. Analog Output Pins

Total Pins: 2

10.2.5. Data and Control Pins

Pin Name	Pin Function	I/O	Internal Pull-up Pull-down	40 Pin loc
GPIO1	General purpose I/O	I/O	none	22
GPIO0	General purpose I/O	I/O	none	21
nRST	Reset	I(Digital)	none	7
ADCBCLK	ADC I ² S shift clock	I/O(Digital)	Pull-Down	14
ADCLRCLK	ADC I ² S framing clock	I/O(Digital)	Pull-Down	15
ADCDOUT	ADC I ² S output data	O(Digital)	Pull-Down	13
DACBCLK	DAC I ² S shift clock	I/O(Digital)	Pull-Down	20
DACLRCLK	DAC I ² S framing clock	I/O(Digital)	Pull-Down	19
DACDIN	DAC I ² S input data	I(Digital)	Pull-Down	18
I2C_SCL	SCL I ² C shift clock	I(Digital)	Pull-Up	12
I2C_SDA	SDA I ² C shift data	I(Digital)	Pull-Up	11
HP_DET	Headphone jack detection	I(Digital)	Pull-Up	29
P_8	Reserved test pin	I(Analog)	None	8

Table 126. Data and Control Pins

Total Pins: 13

10.2.6. PLL Pins

Pin Name	Pin Function	I/O	Internal Pull-up Pull-down	40 Pin loc
MCLK2	MASTER CLK	I(CLK)	NONE	6

Table 127. PLL Pins

Total Pins: 1

10.2.7. No Connetion Pins

Pin Name	40 Pin loc
NC	9,10,23,24,25,26,27

Table 128. PLL Pins

Total Pins: 7

11. PACKAGE DRAWINGS

11.1. 40QFN Package Outline and Package Dimensions

Figure 33. 40QFN Package Diagram

11.2. Pb Free Process- Package Classification Reflow Temperatures

Package Thickness	Volume mm ³ <350	Volume mm ³ 350 - 2000	Volume mm ³ >2000
<1.6mm	260 + 0 °C*	260 + 0 °C*	260 + 0 °C*
1.6mm - 2.5mm	260 + 0 °C*	250 + 0 °C*	245 + 0 °C*
> or = 2.5mm	250 + 0 °C*	245 + 0 °C*	245 + 0 °C*

*Tolerance: The device manufacturer/supplier shall assure process compatibility up to and including the stated classification temperature (this means Peak reflow temperature +0 °C. For example 260 °C+0 °C) at the rated MSL level.

Table 129. Reflow Temperatures

Note: TSI's package thicknesses are <2.5mm and <350 mm³, so 260 applies in every case.

12.APPLICATION INFORMATION

For application information, please see reference designs and application notes available on www.temposemi.com.

TSCS25A3X1NDGXZAX	Analog Microphone in 40 QFN package
-------------------	-------------------------------------

14. DISCLAIMER

While the information presented herein has been checked for both accuracy and reliability, manufacturer assumes no responsibility for either its use or for the infringement of any patents or other rights of third parties, which would result from its use. No other circuits, patents, or licenses are implied. This product is intended for use in normal commercial applications. Any other applications, such as those requiring extended temperature range, high reliability, or other extraordinary environmental requirements, are not recommended without additional processing by manufacturer. Manufacturer reserves the right to change any circuitry or specifications without notice. Manufacturer does not authorize or warrant any product for use in life support devices or critical medical instruments

15. DOCUMENT REVISION HISTORY

Revision	Date	Description of Change
0.5	Feb 2016	Initial release
0.6	Feb 2016	Updated table and PLL's
0.7	Nov 2016	Updated diagrams
0.8	Jan 2017	removed confidential and preliminary
0.9	Jan 2017	corrected SNR information
1.0	April 2017	Corrected Treble and Bass Diagram and Output Power corrections
1.1	April 2017	Format changed
1.2	November 2017	Changed block diagram, added loop back description and table
1.3	December 2017	Removed LoopBack from Block diagram
1.4	March 2018	Edited text mistakes and front page information
1.5	May 2018	Updated text and units for consistency, updated table formatting
1.6	June 2018	Updated target applications on first page. Removed 32 Ohm load HP power number. Updated version number to all pages (previous version still showed v1.4 on certain pages).
