

Multi-Channel Audio Hub CODEC for Smartphones

DESCRIPTION

The WM1811A^[1] is a highly integrated ultra-low power hi-fi CODEC designed for smartphones and other portable devices rich in multimedia features.

An integrated stereo Class D speaker driver and Class W headphone driver minimize power consumption during audio playback.

The device requires only two voltage supplies, with all other internal supply rails generated from integrated LDOs.

Stereo full duplex asynchronous sample rate conversion and multi-channel digital mixing combined with powerful analogue mixing allow the device to support a huge range of different architectures and use cases.

A programmable parametric EQ provides speaker compensation in the digital playback paths. The dynamic range controller can be used in record or playback paths for maintaining a constant signal level, maximizing loudness and protecting speakers against overloading and clipping.

A smart digital microphone interface provides power regulation, a low jitter clock output and decimation filters for up to two digital microphones. Microphone activity detection with interrupt is available.Low power jack detection is supported via a dedicated input pin. Impedance sensing and measurement is provided for external accessory / push-button detection.

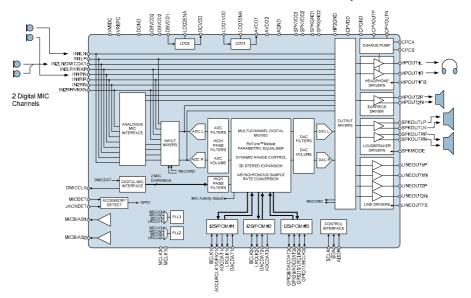

Fully differential internal architecture and on-chip RF noise filters ensure a very high degree of noise immunity. Active ground loop noise rejection and DC offset correction help prevent pop noise and suppress ground noise on the headphone outputs.

FEATURES

- 24-bit 2-channel hi-fi DAC and 2-channel hi-fi ADC
- 100dB SNR during DAC playback ('A' weighted)
- Smart MIC interface
 - Power, clocking and data input for up to two digital MICs
 - High performance analogue MIC interface
 - MIC activity detect & interrupt allows processor to sleep
 - Low power jack detection support
- Impedance sensing for accessory / push-button detection
 2W stereo (2 x 2W) Class D speaker driver
 - Capless Class W headphone drivers
 - Integrated charge pump
 - 5.3mW total power for DAC playback to headphones
- 4 Line outputs (single-ended or differential)
- BTL Earpiece driver
- Digital audio interfaces for multi-processor architecture - Asynchronous stereo duplex sample rate conversion
- Powerful mixing and digital loopback functions
- ReTune™ Mobile 5-band, 4-channel parametric EQ Dynamic range controller
- Dynamic range controller
 - Dual FLL provides all necessary clocks
 Self-clocking modes allow processor to sleep
 - Self-clocking modes allow processor to sleep
 All standard sample rates from 8kHz to 96kHz
- Active noise reduction circuits
- DC offset correction removes pops and clicks
- Ground loop noise cancellation
- Integrated LDO regulators
- 80-ball W-CSP package (4.158 x 3.876 x 0.607mm)

APPLICATIONS

- Smartphones and music phones
- Portable navigation
- Tablets, eBooks
- Portable Media Players

WOLFSON MICROELECTRONICS plc

ORDERING INFORMATION

| ORDER CODE | TEMPERATURERANGE | PACKAGE | MOISTURE SENSITIVITY LEVEL | PEAK SOLDERING TEMPERATURE |
|--------------|------------------|---|-------------------------------|-------------------------------|
| WM1811AECS/R | -40°C to +85°C | 80-ball W-CSP (Pb-free, Tape and reel) | MSL1 | 260°C |

Note:

Reel quantity = 5000

PIN DESCRIPTION

A description of each pin on the WM1811A is provided below.

Note that a table detailing the associated power domain for every input and output pin is provided on the following page. Note that, where multiple pins share a common name, these pins should be tied together on the PCB.

| F4 ADCDAT1 Digital Output Audio interface 1 ADC digital audio data H4 ADCDAT2 Digital Output Audio interface 1 ADC left / right clock / General Purpose pin GPIO 1 F3 ADDR Digital Input / Output Audio interface 1 ADC left / right clock / General Purpose pin GPIO 1 F3 ADDR Digital Input / 2-wire (I2C) address select D9 AGND Supply Analogue ground (Return path for AVDD1, AVDD2 and LDO1VDD) E9, G9 AVDD1 Supply / Analogue Analogue core supply / LDO1 Output G3 BCLK1 Digital Input / Output Audio interface 1 bit clock K1 BCLK2 Digital Input / Output Audio interface 2 bit clock J8 CPCA Analogue Output Charge pump fly-back capacitor pin K8 CPCB Analogue Output Charge pump ground (Return path for CPVDD) J9 CPVODT Analogue Output Charge pump positive supply decoupling pin (HPOUT1L, HPOUT1R) J7 CPVOUTN Analogue Output Charge pump positive supply decoupling in (HPOUT1L, HPOUT1R) J7 CPVOUTN Analogue Output Charge pump positive supply decoupling i | PIN NO | NAME | TYPE | DESCRIPTION |

ABSOLUTE MAXIMUM RATINGS

Absolute Maximum Ratings are stress ratings only. Permanent damage to the device may be caused by continuously operating at or beyond these limits. Device functional operating limits and guaranteed performance specifications are given under Electrical Characteristics at the test conditions specified.

ESD Sensitive Device. This device is manufactured on a CMOS process. It is therefore generically susceptible to damage from excessive static voltages. Proper ESD precautions must be taken during handling and storage of this device.

Wolfson tests its package types according to IPC/JEDEC J-STD-020 for Moisture Sensitivity to determine acceptable storage conditions prior to surface mount assembly. These levels are:

MSL1 = unlimited floor life at <30°C / 85% Relative Humidity. Not normally stored in moisture barrier bag.

MSL2 = out of bag storage for 1 year at <30°C / 60% Relative Humidity. Supplied in moisture barrier bag.

MSL3 = out of bag storage for 168 hours at <30°C / 60% Relative Humidity. Supplied in moisture barrier bag.

The Moisture Sensitivity Level for each package type is specified in Ordering Information.

| CONDITION | MIN | MAX |
|--|----------------|--------------|
| Supply voltages (AVDD1, DBVDD2, DBVDD3) | -0.3V | +4.5V |
| Supply voltages (AVDD2, DCVDD, DBVDD1) | -0.3V | +2.5V |
| Supply voltages (CPVDD) | -0.3V | +2.2V |
| Supply voltages (SPKVDD1, SPKVDD2, LDO1VDD) | -0.3V | +7.0V |
| Voltage range digital inputs (DBVDD1 domain) | AGND -0.3V | DBVDD1 +0.3V |
| Voltage range digital inputs (DBVDD2 domain) | AGND -0.3V | DBVDD2 +0.3V |
| Voltage range digital inputs (DBVDD3 domain) | AGND -0.3V | DBVDD3 +0.3V |
| Voltage range digital inputs (DMICDAT) | AGND -0.3V | AVDD1 +0.3V |
| Voltage range analogue inputs(AVDD1 domain) | AGND -0.3V | AVDD1 +0.3V |
| Voltage range analogue inputs (MICDET, LINEOUTFB) | AGND -0.3V | AVDD1 +0.3V |
| Voltage range analogue inputs (HPOUT1FB) | AGND -0.3V | AGND +0.3V |
| Voltage range analogue inputs (JACKDET) | CPVOUTN - 0.3V | AVDD2 +0.3V |
| See note 1 | | |
| Ground (DGND, CPGND, SPKGND1, SPKGND2, REFGND, HP2GND) | AGND -0.3V | AGND +0.3V |
| Operating temperature range, T _A | -40°C | +85°C |
| Junction temperature, T _{JMAX} | -40°C | +150°C |
| Storage temperature after soldering | -65°C | +150°C |

Notes:

1. CPVOUTN is an internal supply rail, generated by the WM1811A Charge Pump. The CPVOUTN voltage may vary between AGND and -CPVDD.

RECOMMENDED OPERATING CONDITIONS

| PARAMETER | SYMBOL | MIN | TYP | MAX | UNIT |
|-----------------------------|---|------|------|-----|------|
| Digital supply range (Core) | DCVDD | 1.00 | 1.05 | 2.0 | V |
| See notes 7, 8 | | | | | |
| Digital supply range (I/O) | DBVDD1 | 1.62 | 1.8 | 2.0 | V |
| Digital supply range (I/O) | DBVDD2, DBVDD3 | 1.62 | 1.8 | 3.6 | V |
| Analogue supply 1 range | AVDD1 | 2.4 | 3.0 | 3.3 | V |
| See notes 3, 4, 5, 6 | | | | | |
| Analogue supply 2 range | AVDD2 | 1.71 | 1.8 | 2.0 | V |
| Charge Pump supply range | CPVDD | 1.71 | 1.8 | 2.0 | V |
| Speaker supply range | SPKVDD1, SPKVDD2 | 2.7 | 5.0 | 5.5 | V |
| LDO1 supply range | LDO1VDD | 2.7 | 5.0 | 5.5 | V |
| Ground | DGND, AGND, CPGND, SPKGND1, SPKGND2, REFGND, HP2GND | | 0 | | V |
| Power supply rise time | All supplies | 1 | | | μS |
| See notes 9, 10, 11 | | | | | |
| Operating temperature range | T _A | -40 | | 85 | °C |

Notes:

1. Analogue, digital and speaker grounds must always be within 0.3V of AGND.

- 2. There is no power sequencing requirement; the supplies may be enabled in any order.
- 3. AVDD1 must be less than or equal to SPKVDD1 and SPKVDD2.
- 4. An internal LDO (powered by LDO1VDD) can be used to provide the AVDD1 supply.
- 5. When AVDD1 is supplied externally (not from LDO1), the LDO1VDD voltage must be greater than or equal to AVDD1.
- 6. The WM1811A can operate with AVDD1 tied to 0V; power consumption may be reduced, but the analogue audio functions will not be supported.
- 7. An internal LDO (powered by DBVDD1) can be used to provide the DCVDD supply.
- 8. When DCVDD is supplied externally (not from LDO2), the DBVDD1voltage must be greater than or equal to DCVDD.
- 9. DCVDD and AVDD1 minimum rise times do not apply when these domains are powered using the internal LDOs.
- 10. The specified minimum power supply rise times assume a minimum decoupling capacitance of 100nF per pin. However, Wolfson strongly advises that the recommended decoupling capacitors are present on the PCB and that appropriate layout guidelines are observed (see "Applications Information" section).
- 11. The specified minimum power supply rise times also assume a maximum PCB inductance of 10nH between decoupling capacitor and pin.

ELECTRICAL CHARACTERISTICS

INPUT SIGNAL LEVEL

Test Conditions

AVDD1 = 3.0V.

With the exception of the condition(s) noted above, the following electrical characteristics are valid across the full range of recommended operating conditions.

| PARA | METER | TES | T CONDITIONS | MIN | TYP | MAX | UNIT |
|------|--|--|--|-----|----------|-----|-------------|
| A1 | Full-Scale PGA Input Signal Level See notes 1, 2, 3 and 4 | Single-ended PGA input | IN1LN, IN1L, IN2LN, IN2L, IN1RN or IN1R or IN2RN + VMID + | | 1.0 0 | | Vrms dBV |
| | | Differential PGA input | IN1LN, IN1L, IN2LN, IN2L, IN1RN or IN1R or IN2RN IN1LP, IN1LP, IN1RP or IN2RP | | 1.0 0 | | Vrms dBV |
| A2 | Full-Scale Line Input Signal Level See notes 1, 2, 3 and 4 | Single-ended Line input to MIXINL/R, SPKMIXL/R or MIXOUTL/R mixers | | | 1.0 0 | | Vrms dBV |
| | | Differential mono line input on VRXP/VRXN to RXVOICE | RXVOICE path | | 1.0 0 | | Vrms dBV |

Notes:

1. The full-scale input signal level changes in proportion with AVDD1. It is calculated as AVDD1/3.0.

2. When mixing line inputs, input PGA outputs and DAC outputs the total signal must not exceed 1.0Vrms (0dBV).

3. A 1.0Vrms differential signal equates to 0.5Vrms/-6dBV per input.

4. A sinusoidal input signal is assumed.

INPUT PIN RESISTANCE

Test Conditions

 $T_A = +25^{\circ}C.$

With the exception of the condition(s) noted above, the following electrical characteristics are valid across the full range of recommended operating conditions.

| PARA | METER | TEST | CONDITIONS | MIN | TYP | MAX | UNIT |
|------|---|---|--|-----|-----|-----|------|

OUTPUT DRIVER CHARACTERISTICS

Test Conditions

The following electrical characteristics are valid across the full range of recommended operating conditions.

| PARAMETER | TEST CONDITIONS | MIN | TYP | MAX | UNIT |
|---------------------------------------|--|-----|-----|------|------|
| Line Output Driver (LINEOUT1P, LINEOU | IT1N, LINEOUT2P, LINEOUT2N) | | | | |
| Load resistance | | 2 | | | kΩ |
| Load capacitance | Direct connection | | | 100 | pF |
| | Connection via 1kΩ series resistor | | | 2000 | |
| Output discharge resistance | LINEOUTn_DISCH=1, VROI=0 | | 8 | | kΩ |
| | LINEOUTn_DISCH=1, VROI=1, | | 500 | | Ω |
| | LINEOUTn_ENA=0 | | | | |
| Headphone Output Driver (HPOUT1L, HF | POUT1R) | | | | |
| Load resistance | Normal operation | 15 | | | Ω |
| | Device survival with load applied indefinitely | 100 | | | mΩ |
| | (see note 6) | | | | |
| Load capacitance | | | | 500 | pF |
| Earpiece Output Driver (HPOUT2L, HPO | JT2R) | | | | |
| Load resistance | | 15 | | | Ω |
| Load capacitance | Direct connection | | | 200 | pF |
| DC offset across load | | | ±5 | | mV |
| Speaker Output Driver (SPKOUTLP, SPK | OUTLN, SPKOUTRP, SPKOUTRN) | | | | |
| Load resistance | | 4 | | | Ω |
| Maximum output power (per channel) | Design rating | | 2 | | W |
| DC offset across load | | | ±5 | | mV |
| SPKVDD leakage current | Sum of I _{SPKVDD1} + I _{SPKVDD2} | | 1 | | μA |

Note 6: In typical applications, the PCB trace resistance, jack contact resistanceand ESR of any series passive components (eg. inductor or ferrite bead) are sufficient to provide this minimum resistance; additional series components are not required.

ADC INPUT PATH PERFORMANCE

Test Conditions

TERMINOLOGY

- 1. Signal-to-Noise Ratio (dB) SNR is a measure of the difference in level between the maximum full scale output signal and the output with no input signal applied.
- 2. Total Harmonic Distortion (dB) THD is the level of the rms value of the sum of harmonic distortion products relative to the amplitude of the measured output signal.
- 3. Total Harmonic Distortion plus Noise (dB) THD+N is the level of the rms value of the sum of harmonic distortion products plus noise in the specified bandwidth relative to the amplitude of the measured output signal.
- 4. Power Supply Rejection Ratio (dB) PSRR is the ratio of a specified power supply variation relative to the output signal that results from it. PSRR is measured under quiescent signal path conditions.
- 5. Common Mode Rejection Ratio (dB) CMRR is the ratio of a specified input signal (applied to both sides of a differential input), relative to the output signal that results from it.
- 6. Channel Separation (L/R) (dB) left-to-right and right-to-left channel separation is the difference in level between the active channel (driven to maximum full scale output) and the measured signal level in the idle channel at the test signal frequency. The active channel is configured and supplied with an appropriate input signal to drive a full scale output, with signal measured at the output of the associated idle channel.
- 7. Multi-PathCrosstalk (dB) is the difference in level between the output of the active path and the measured signal level in the idle path at the test signal frequency. The active path is configured and supplied with an appropriate input signal to drive a full scale output, with signal measured at the output of the specified idle path.
- 8. Mute Attenuation This is a measure of the difference in level between the full scale output signal and the output with mute applied.
- 9. All performance measurements carried out with 20kHz low pass filter, and where noted an A-weighted filter. Failure to use such a filter will result in higher THD and lower SNR readings than are found in the Electrical Characteristics. The low pass filter removes out of band noise; although it is not audible it may affect dynamic specification values.

| BCLK cycle time | t _{BCY} | 80 | | | ns |
| ADCDAT propagation delay from BCLK falling edge | t _{DDA} | | | 24 | ns |

Note that the descriptions above assume non-inverted polarity of BCLK and LRCLK.

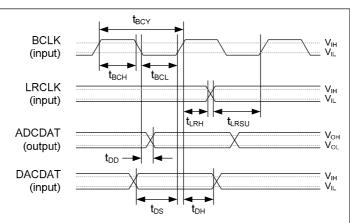

Figure 4 Audio Interface Timing - Slave Mode

Note that BCLK and LRCLK inputs can be inverted if required; Figure 4 shows the default, non-inverted polarity.

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

| PARAMETER | SYMBOL | MIN | ТҮР | MAX | UNIT |
|---|-------------------|-----|-----|-----|------|
| Audio Interface Timing - Slave Mode | | | | | |
| BCLK cycle time | t _{BCY} | 160 | | | ns |
| BCLK pulse width high | t _{BCH} | 64 | | | ns |
| BCLK pulse width low | t _{BCL} | 64 | | | ns |
| LRCLK set-up time to BCLK rising edge | t _{LRSU} | 10 | | | ns |
| LRCLK hold time from BCLK rising edge | t _{LRH} | 10 | | | ns |
| DACDAT hold time from BCLK rising edge | t _{DH} | 10 | | | ns |
| ADCDAT propagation delay from BCLK falling edge | t _{DD} | | | 48 | ns |
| DACDAT set-up time to BCLK rising edge | t _{DS} | 32 | | | ns |

Note that the descriptions above assume non-inverted polarity of BCLK and LRCLK.

DIGITAL AUDIO INTERFACE - TDM MODE

When TDM operation is used on the ADCDATn pins, it is important that two devices do not attempt to drive the ADCDATn pin simultaneously. To support this requirement, the ADCDATn pins can be configured to be tri-stated when not outputting data.

The timing of the ADCDATn tri-stating at the start and end of the data transmission is described in Figure 5 below.

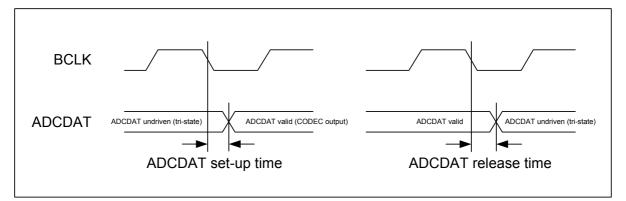

Figure 5 Audio Interface Timing- TDM Mode

Test Conditions

The following timing information is valid across the full range of recommended operating conditions.

| PARAMETER | MIN | TYP | MAX | UNIT | | | | |
|--|-----|-----|-----|------|--|--|--|--|
| TDM Timing - Master Mode | | | | | | | | |
| ADCDATsetup time from BCLKfalling edge | 0 | | | ns | | | | |
| ADCDATrelease time from BCLKfalling edge | | | 15 | ns | | | | |
| TDM Timing - Slave Mode | | | | | | | | |
| ADCDAT setup time from BCLK falling edge | 5 | | | ns | | | | |
| ADCDAT release time from BCLK falling edge | | | 32 | ns | | | | |

DEVICE DESCRIPTION

INTRODUCTION

The WM1811A is a low power, high quality audio codec designed to interface with a wide range of processors and analogue components. A high level of mixed-signal integration in a very small footprint makes it ideal for portable applications such as mobile phones.Fully differential internal architecture and on-chip RF noise filters ensure a very high degree of noise immunity.

Three sets of audio interface pins are available in order to provide independent and fully asynchronous connections to multiple processors, typically an application processor, baseband processor and wireless transceiver. Any two of these interfaces can operate totally independently and asynchronously while the third interface can be synchronised to either of the other two and can also provide ultra low power loopback modes to support, for example, wireless headset voice calls.

The WM1811A provides a two-channel digital microphone interface, suitable for noise cancellation and other applications. An integrated microphone activity monitor is available to enable the processor to sleep during periods of microphone inactivity, saving power.

Eight highly flexible analogue inputs allow interfacing to up to four microphone inputs (single-ended or differential), plus multiple stereo or mono line inputs. Connections to an external voice CODEC, FM radio, line input, handset MIC and headset MIC are all fully supported. Signal routing to the output mixers and within the CODEC has been designed for maximum flexibility to support a wide variety of usage modes.

Impedance sensing and measurement for external accessories is provided, for detection of the insertion or removal of microphones and other accessories. Push-button detection of up to 7 inputs can be supported using this feature.Low power jack detection is supported, using a dedicated input pin; this enables power consumption to be minimised in standby conditions, whilst awaiting an external jack insertion event.

Nine analogue output drivers are integrated, including a stereo pair of high power, high quality Class D speaker drivers; these can support 2Weach in stereo mode. It is also possible to configure the speaker drivers as a mono output, giving enhanced performance. A mono earpiece driver is provided, providing an additional output from the output mixers.

One pair of ground-referenced headphone outputs is provided; these are powered from an integrated Charge Pump, enabling high quality, power efficient headphone playback without any requirement for DC blocking capacitors. A DC Servo circuit is available for DC offset correction, thereby suppressing pops and reducing power consumption. Four line outputs are provided, with multiple configuration options including 4 x single-ended outputs or 2 x differential outputs. The line outputs are suitable for output to a voice CODEC, an external speaker driver or line output connector. Ground loop feedback is available on the headphone outputs and the line outputs, providing rejection of noise on the ground connections. All outputs have integrated pop and click suppression features.

Internal differential signal routing and amplifier configurations have been optimised to provide the highest performance and lowest possible power consumption for a wide range of usage scenarios, including voice calls and music playback. The speaker drivers offer low leakage and high PSRR; this enables direct connection to a Lithium battery. The speaker drivers provide eight levels of AC and DC gain to allow output signal levels to be maximised for many commonly-used SPKVDD/AVDD1 combinations.

The ADCs and DACs are of hi-fi quality, using a 24-bit low-order oversampling architecture to deliver optimum performance. A flexible clocking arrangement supports mixed sample rates, whilst integrated ultra-low power dual FLLs provide additional flexibility. A high pass filter is available in all ADC and digital MIC paths for removing DC offsets and suppressing low frequency noise such as mechanical vibration and wind noise. A digital mixing path from the ADC or digital MICs to the DAC provides a sidetone of enhanced quality during voice calls. DAC soft mute and un-mute is available for pop-free music playback.

The integrated Dynamic Range Controllers (DRC) and ReTune[™] Mobile 5-band parametric equaliser (EQ) provide further processing capability of the digital audio paths. The DRC provides compression and signal level control to improve the handling of unpredictable signal levels. 'Anti-clip' and 'quick release' algorithms improve intelligibility in the presence of transients and impulsive noises. The EQ provides the capability to tailor the audio path according to the frequency characteristics of an earpiece or loudspeaker, and/or according to user preferences.

PD, August 2014, Rev 4.2

The WM1811A has highly flexible digital audio interfaces, supporting a number of protocols, including I²S, DSP, MSB-first left/right justified, and can operate in master or slave modes. PCM operation is supported in the DSP mode. A-law and μ -law companding are also supported. Time division multiplexing (TDM) is available to allow multiple devices to stream data simultaneously on the same bus, saving space and power.

A powerful digital mixing core allows data from each audio interface channel and from the ADCs and digital MICs to be mixed and re-routed back to a different audio interface and to the DAC output paths. The digital mixing core can operate synchronously with either Audio Interface 1 or Audio Interface 2, with asynchronous stereo full duplex sample rate conversion performed on the other audio interface as required.

The system clock (SYSCLK) provides clocking for the ADCs, DACs, DSP core, digital audio interface and other circuits. SYSCLK can be derived directly from one of the MCLK1 or MCLK2 pins or via one of two integrated FLLs, providing flexibility to support a wide range of clocking schemes, including self-clocking FLL modes. Typical portable system MCLK frequencies, and sample rates from 8kHz to 96kHz are all supported. A low frequency (eg. 32.768kHz) clock can be used as the input reference to the FLLs, providing further flexibility. Automatic configuration of the clocking circuits is available, derived from the sample rate and from the MCLK / SYSCLK ratio.

The WM1811A uses a standard 2-wire control interface, providing full software control of all features, together with device register readback. It is an ideal partner for a wide range of industry standard microprocessors, controllers and DSPs. Unused circuitry can be disabled under software control, in order to save power; low leakage currents enable extended standby/off time in portable battery-powered applications.

Versatile GPIO functionality is provided, with support for button/accessory detect inputs, or for clock, system status, or programmable logic level output for control of additional external circuitry. Interrupt logic, status readback and de-bouncing options are supported within this functionality.

ANALOGUE INPUT SIGNAL PATH

The WM1811A has eight highly flexible analogue input channels, configurable in a large number of combinations:

1. Up to four fully differential or single-ended microphone inputs

2. Up to eight mono line inputs or 4 stereo line inputs

3. A dedicated mono differential input from external voice CODEC

These inputs may be mixed together or independently routed to different combinations of output drivers. An internal record path is provided at the input mixers to allow DAC output to be mixed with the input signal path (e.g. for voice call recording).

The WM1811A input signal paths and control registers are illustrated in Figure 7.

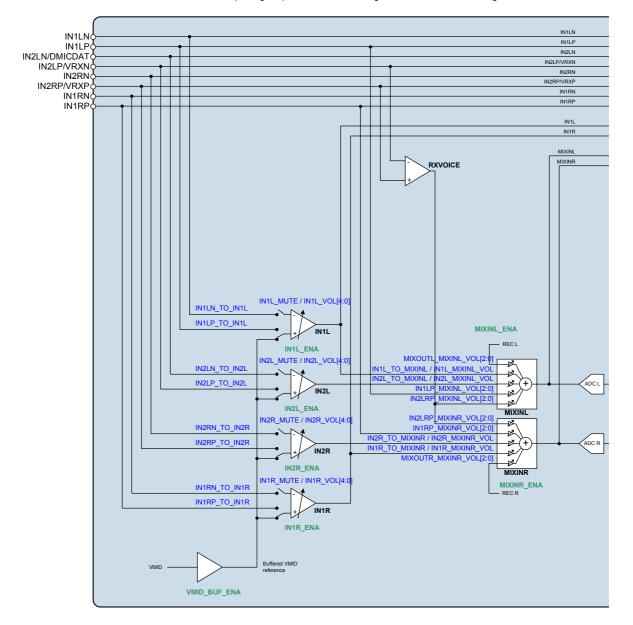

Figure 7 Control Registers for Input Signal Path

MICROPHONE INPUTS

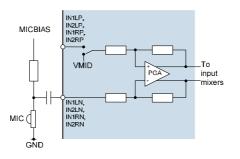

Up to four analogue microphones can be connected to the WM1811A, either in single-ended or differential mode. A dedicated PGA is provided for each microphone input. Two low noise microphone bias circuits are provided, reducing the need for external components.

For single-ended microphone inputs, the microphone signal is connected to the inverting input of the PGAs (IN1LN, IN2LN, IN1RN or IN2RN). The non-inverting inputs of the PGAs are internally connected to VMID in this configuration. The non-inverting input pins IN1LP, IN2LP, IN1RP and IN2RP are free to be used as line connections to the input or output mixers in this configuration.

For differential microphone inputs, the non-inverted microphone signal is connected to the non-inverting input of the PGAs (IN1LP, IN2LP, IN1RP or IN2RP), whilst the inverted (or 'noisy ground') signal is connected to the inverting input pins (IN1LN, IN2LN, IN1RN and IN2RN).

The gain of the input PGAs is controlled via register settings, as defined in Table 4. Note that the input impedance of both inverting and non-inverting inputs changes with the input PGA gain setting, as described under "Electrical Characteristics". See also the "Applications Information" for details of input resistance at all PGA Gain settings.

The microphone input configurations are illustrated in Figure 8 and Figure 9. Note that any PGA input pin that is used in either microphone configuration is not available for use as a line input path at the same time.

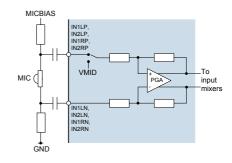

Figure 8 Single-Ended Microphone Input

Figure 9 Differential Microphone Input

MICROPHONE BIAS CONTROL

There are two MICBIAS generators which provide low noise reference voltages suitable for powering silicon (MEMS) microphones or biasing electret condenser (ECM) type microphones via an external resistor. Refer to the "Applications Information" section for recommended external components.

The MICBIAS outputs can be independently enabled using the MICB1_ENA and MICB2_ENA register bits. Under default conditions, a smooth pop-free profile of the MICBIAS outputs is implemented when MICB1_ENA or MICB2_ENA is enabled or disabled; a faster transition can be selected by setting the MICB1 RATE and MICB2 RATE registers as described in Table 1.

When a MICBIAS output is disabled, the output pin can be configured to be floating or to be actively discharged. This is selected using the MICB1_DISCH and MICB2_DISCH register bits.

The MICBIAS generators can each operate as a voltage regulator or in bypass mode.

In Regulator mode, the output voltage is selected using the MICB1_LVL and MICB2_LVL register bits.In this mode, AVDD1 must be at least 200mV greater than the required MICBIAS output voltages.The MICBIAS outputs are powered from the AVDD1 supply pin, and use the internal bandgap circuit as a reference.

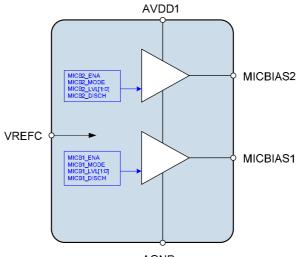

Note that, in Regulator mode, the MICBIAS regulators are designed to operate without external decoupling capacitors. It is important that parasitic capacitances on the MICBIAS1 or MICBIAS2 pins do not exceed the specified limit in Regulator mode (see "Electrical Characteristics").

In Bypass mode, the output pin (MICBIAS1 or MICBIAS2) is connected directly to AVDD1. This enables a low power operating state. Note that, if a capacitive load is connected to MICBIAS1 or

 $\mathsf{MICBIAS2}$ (eg. for a digital microphone supply), then the respective $\mathsf{MICBIAS}$ generator must be configured in Bypass mode.

The MICBIAS configuration is illustrated in Figure 10.

Table 1 Microphone Bias Control

Note that the maximum source current capability for MICBIAS1 and MICBIAS2 is 2.4mA each in Regulator mode. The external biasing resistance must be large enough to limit each MICBIAS current to 2.4mA across the full microphone impedance range. The maximum source current for MICBIAS1 and MICBIAS2 is 3.6mA each in Bypass mode, as described in the "Electrical Characteristics".

MICROPHONE ACCESSORY DETECT

The WM1811A provides a microphone detection function, which uses impedance measurement to detect one or more different external accessory connections. This feature is described in the "External Accessory Detection" section.

LINE AND VOICE CODEC INPUTS

All eight analogue input pins may be used as line inputs. Each line input has different signal path options, providing flexibility, high performance and low power consumption for many different usage modes.

IN1LN and IN1RN can operate as single-ended line inputs to the input PGAs IN1L and IN1R respectively. These inputs provide a high gain path if required for low input signal levels.

IN2LN and IN2RN can operate as single-ended line inputs to the input PGAs IN2L and IN2R respectively, providing further high gain signal paths. These pins can also be connected to either of the output mixers MIXOUTL and MIXOUTR.

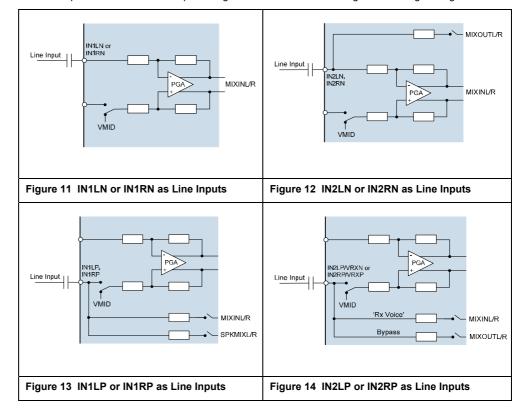

IN1LP and IN1RP can operate as single-ended line inputs to the input mixers MIXINL and MIXINR, or to the speaker mixers SPKMIXL and SPKMIXR. These signal paths enable power consumption to be reduced, by allowing the input PGAs and other circuits to be disabled if not required.

IN2LP/VRXN and IN2RP/VRXP can operate in three different ways:

- Mono differential 'RXVOICE' input (e.g. from an external voice CODEC) to the input mixers MIXINL and MIXINR.
- Single-ended line inputs to either of the output mixers MIXOUTL and MIXOUTR.

Signal path configuration to the input PGAs and input mixers is detailed later in this section. Signal path configuration to the output mixers and speaker mixers is described in "Analogue Output Signal Path".

The line input and voice CODEC input configurations are illustrated in Figure 11 through to Figure 14.

INPUT PGA ENABLE

The Input PGAs are enabled using register bits IN1L_ENA, IN2L_ENA, IN1R_ENA and IN2R_ENA, as described in Table 2. The Input PGAs must be enabled for microphone input on the respective input pins, or for line input on the inverting input pins IN1LN, IN1RN, IN2LN, IN2RN.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|----------|---------|-----------------------|
| R2 (0002h) | 7 | IN2L_ENA | 0 | IN2L Input PGA Enable |
| Power | | | | 0 = Disabled |
| Management | | | | 1 = Enabled |
| (2) | 6 | IN1L_ENA | 0 | IN1L Input PGA Enable |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |
| | 5 | IN2R_ENA | 0 | IN2R Input PGA Enable |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |
| | 4 | IN1R_ENA | 0 | IN1R Input PGA Enable |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |

Table 2 Input PGA Enable

For normal operation of the input PGAs, the reference voltage VMID and the bias current must also be enabled. See "Reference Voltages and Master Bias" for details of the associated controls VMID_SEL and BIAS_ENA.

INPUT PGA CONFIGURATION

Each of the Input PGAs can operate in a single-ended ordifferential mode. In differential mode, both inputs to the PGA are connected to the input source. In single-ended mode, the non-inverting input to the PGA must be connected to VMID. Configuration of the PGA inputs to the WM1811A input pins is controlled using the register bits shown in Table 3.

Single-ended microphone operation is configured by connecting the input source to the inverting input of the applicable PGA. The non-inverting input of the PGA must be connected to the buffered VMID reference. Note that the buffered VMID reference must be enabled, using the VMID_BUF_ENA register, as described in "Reference Voltages and Master Bias".

Differential microphone operation is configured by connecting the input source to both inputs of the applicable PGA.

Line inputs to the input pins IN1LN, IN2LN, IN1RN and IN2RN must be connected to the applicable PGA. The non-inverting input of the PGA must be connected to VMID.

Line inputs to the input pins IN1LP, IN2LP, IN1RP or IN2RP do not connect to the input PGAs. The non-inverting inputs of the associated PGAs must be connected to VMID. The inverting inputs of the associated PGAs may be used as separate mic/line inputs if required.

The maximum available attenuation on any of these input paths is achieved by using register bits shown in Table 3 to disconnect the input pins from the applicable PGA.

Table 3 Input PGA Configuration

INPUT PGA VOLUME CONTROL

Each of the four Input PGAs has an independently controlled gain range of -16.5dB to +30dB in 1.5dB steps. The gains on the inverting and non-inverting inputs to the PGAs are always equal. Each Input PGA can be independently muted using the PGA mute bits as described in Table 4, with maximum mute attenuation achieved by simultaneously disconnecting the corresponding inputs described in Table 3.

Note that, under default conditions (following power-up or software reset), the PGA mute register bits are set to '1', but the mute functions will only become effective after the respective bit has been toggled to '0' and then back to '1'. The Input PGAs will be un-muted (Mute disabled) after power-up or software reset, regardless of the readback value of the respective PGA mute bits.

To prevent "zipper noise", a zero-cross function is provided on the input PGAs. When this feature is enabled, volume updates will not take place until a zero-crossing is detected. In the case of a long period without zero-crossings, a timeout function is provided. When the zero-cross function is enabled, the volume will update after the timeout period if no earlier zero-cross has occurred. The timeout clock is enabled using TOCLK_ENA, the timeout period is set by TOCLK_DIV. See "Clocking and Sample Rates" for more information on these fields.

The IN1_VU and IN2_VU bits control the loading of the input PGA volume data. When IN1_VU and IN2_VU are set to 0, the PGA volume data will be loaded into the respective control register, but will not actually change the gain setting. The IN1L and IN1R volume settings are both updated when a 1 is written to IN1_VU; the IN2L and IN2R volume settings are both updated when a 1 is written to IN2_VU. This makes it possible to update the gain of the left and right signal paths simultaneously.

INPUT MIXER ENABLE

The WM1811A has two analogue input mixers which allow the Input PGAs and Line Inputs to be combined in a number of ways and output to the ADCs, Output Mixers, or directly to the output drivers via bypass paths.

The input mixers MIXINL and MIXINR are enabled by the MIXINL_ENA and MIXINR_ENA register bits, as described in Table 6. These control bits also enable the RXVOICE input path, described in the following section.

For normal operation of the input mixers, the reference voltage VMID and the bias current must also be enabled. See "Reference Voltages and Master Bias" for details of the associated controls VMID_SEL and BIAS_ENA.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|------------|---------|---|
| R2 (0002h) | 9 | MIXINL_ENA | 0 | Left Input Mixer Enable |
| Power Management | | | | (Enables MIXINL and RXVOICE input to MIXINL) |
| (2) | | | | 0 = Disabled |
| | | | | 1 = Enabled |
| | 8 | MIXINR_ENA | 0 | Right Input Mixer Enable |
| | | | | (Enables MIXINR and RXVOICE input to MIXINR) |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |

Table 6 Input Mixer Enable

INPUT MIXER CONFIGURATION AND VOLUME CONTROL

The left and right channel input mixers MIXINL and MIXINR can be configured to take input from up to five sources:

- 1. IN1L or IN1R Input PGA
- 2. IN2L or IN2R Input PGA
- 3. IN1LP or IN1RP pin (PGA bypass)
- 4. RXVOICE mono differential input from IN2LP/VRXN and IN2RP/VRXP
- 5. MIXOUTL or MIXOUTR Output Mixer (Record path)

The Input Mixer configuration and volume controls are described in Table 7 for the Left input mixer (MIXINL) and Table 8 for the Right input mixer (MIXINR). The signal levels from the Input PGAs may be set to Mute, 0dB or 30dB boost. Gain controls for the PGA bypass, RXVOICE and Record paths provide adjustment from -12dB to +6dB in 3dB steps.

When using the IN1LP or IN1RP signal paths direct to the input mixers (PGA bypass paths), a signal gain of +15dB can be selected using the IN1RP_MIXINR_BOOST or IN1LP_MIXINL_BOOST register bits. See Table 7 and Table 8 for further details.

When using the IN1LP or IN1RP signal paths direct to the input mixers (PGA bypass paths), the buffered VMID reference must be enabled, using the VMID_BUF_ENA register, as described in "Reference Voltages and Master Bias".

To prevent pop noise, it is recommended that gain and mute controls for the input mixers are not modified while the signal paths are active. If volume control is required on these signal paths, it is recommended that this is implemented using the input PGA volume controls or the ADC volume controls. The ADC volume controls are described in the "Analogue to Digital Converter (ADC)" section.

Table 8 Right Input Mixer (MIXINR) Volume Control

DIGITAL MICROPHONE INTERFACE

The WM1811A supports a stereo digital microphone interface. Two channels of audio data are multiplexed on the DMICDAT pin; the data is clocked using the DMICCLK output pin.

The DMICDAT function is shared with the IN2LN pin; the analogue signal paths from IN2LN cannot be used when this pin is used for DMICDAT digital microphone input.

The digital microphone interface is referenced to the MICBIAS1 voltage domain; the MICBIAS1 output must be enabled (MICB1_ENA = 1) when using the digital microphone interface.

The MICBIAS1 generator is suitable for use as a low noise supply for the digital microphones. Note that, if the capacitive load on the MICBIAS1 generator exceeds the specified limit (eg. due to a decoupling capacitor or long PCB trace), then the MICBIAS1 generator must be configured in Bypass mode. See "Analogue Input Signal Path" for details of the MICBIAS1 generator.

When digital microphone input is enabled, the WM1811A outputs a clock signal on the DMICCLK pin.

A pair of digital microphones is connected as illustrated in Figure 15. The microphones must be configured to ensure that the Left mic transmits a data bit when DMICCLK is high, and the Right mic transmits a data bit when DMICCLK is low. The WM1811A samples the digital microphone data at the end of each DMICCLK phase. Each microphone must tri-state its data output when the other microphone is transmitting.

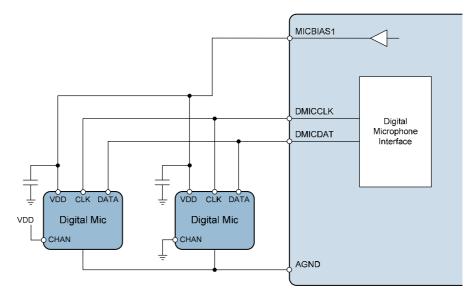

Figure 15 Digital Microphone Input

The DMICDAT digital microphone channels are enabled using DMIC1L_ENA and DMIC1R_ENA. When these signal paths are enabled, the respective ADC path is disconnected and the digital microphone data is routed to the digital mixing input bus, as illustrated in "Digital Mixing".

Two microphone channels are interleaved on DMICDAT; the timing is illustrated in Figure 16. Each microphone must tri-state its data output when the other microphone is transmitting.

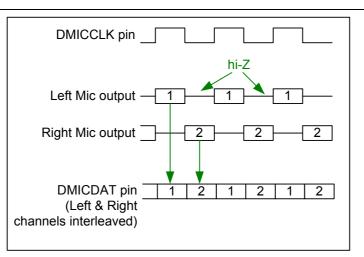

Figure 16 Digital Microphone Interface Timing

The digital microphone channels can be routed to the AIF1 digital audio interface output paths.

Digital volume control of the digital microphone channels in the AIF1 signal paths is provided using the registers described in the "Digital Volume and Filter Control" section.

The digital microphone channels can also be routed, in a limited number of configurations, to the digital mixing output bus, via the digital sidetone signal paths. See "Digital Mixing" for further details.

Digital volume control of the digital microphone channels in the digital sidetone signal paths is provided using the registers described in the "Digital Mixing" section.

The digital microphone interface control fields are described in Table 9.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|--|-----|------------|---------|---|
| R4 (0004h) Power Management (4) | 3 | DMIC1L_ENA | 0 | Digital microphone (DMICDAT) Left channel enable 0 = Disabled 1 = Enabled |
| | 2 | DMIC1R_ENA | 0 | Digital microphone (DMICDAT) Right channel enable 0 = Disabled 1 = Enabled |

Table 9 Digital Microphone Interface Control

Clocking for the Digital Microphone interface is derived from SYSCLK. The DMICCLK frequency is configured automatically, according to the AIFn_SR, AIFnCLK_RATE and ADC_OSR128 registers. (See "Clocking and Sample Rates" for further details of the system clocks and control registers.)

The DMICCLK is enabled whenever a digital microphone input path is enabled on the DMICDATpin. Note that the SYSDSPCLK_ENA register must also be set.

When AIF1CLK is selected as the SYSCLK source (SYSCLK_SRC = 0), then the DMICCLK frequency is controlled by the AIF1_SR and AIF1CLK_RATE registers.

When AIF2CLK is selected as the SYSCLK source (SYSCLK_SRC = 1), then the DMICCLK frequency is controlled by the AIF2_SR and AIF2CLK_RATE registers.

The DMICCLK frequency is as described in Table 10 (for ADC_OSR128=1) and Table 11 (for ADC_OSR128=0). The ADC_OSR128 bit is set by default, giving best audio performance. Note that the only valid DMICCLK configurations are the ones listed in Table 10 and Table 11.

The applicable clocks (SYSCLK, and AIF1CLK or AIF2CLK) must be present and enabled when using the digital microphone interface.

| SAMPLE | | SYSCLK RATE (AIFnCLK / fs ratio) | | | | | | | |
|--|-----|----------------------------------|--------|-----|--------|-------|--------|-------|--|
| RATE (kHz) | 128 | 192 | 256 | 384 | 512 | 768 | 1024 | 1536 | |

| 88.2 | | | | | | | | |
| 96 | | | | | | | | |
| Note that, when ADC_OSR128=0, digital microphone operation is only supported for the above DMICCLK configurations. | | | | | | | | |

Table 11 DMICCLK Frequency (MHz) - ADC_OSR128 = 0

DIGITAL PULL-UP AND PULL-DOWN

The WM1811A provides integrated pull-up and pull-down resistors on the DMICDAT pin. This provides a flexible capability for interfacing with other devices. Each of the pull-up and pull-down resistors can be configured independently using the register bits described in Table 12.

| Note that, if the DMICDAT | digital microphone | channels are disabled, | or if DMICDAT1_PU and |
|---------------------------|----------------------|---------------------------|-----------------------|
| DMICDAT1_PD are both set | then the pull-up and | pull-down will be disable | ed. |

| (1) | 8 | DMICDAT1_PD | 0 | DMICDAT Pull-Down enable 0 = Disabled 1 = Enabled |

Table 12 Digital Pull-Up and Pull-Down Control

ANALOGUE TO DIGITAL CONVERTER (ADC)

The WM1811A uses stereo 24-bit sigma-delta ADCs. The use of multi-bit feedback and high oversampling rates reduces the effects of jitter and high frequency noise. The oversample rate can be adjusted, if required, to reduce power consumption - see "Clocking and Sample Rates" for details. The ADC full scale input level is proportional to AVDD1 - see "Electrical Characteristics". Any input signal greater than full scale may overload the ADC and cause distortion.

The ADCs are enabled by the ADCL_ENA and ADCR_ENA register bits.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|----------|---------|------------------|
| R4 (0004h) | 1 | ADCL_ENA | 0 | Left ADC Enable |
| Power | | | | 0 = Disabled |
| Management (4) | | | | 1 = Enabled |
| | 0 | ADCR_ENA | 0 | Right ADC Enable |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |

Table 13 ADC Enable Control

The outputs of the ADCs can be routed to the AIF1 digital audio interface output paths.

Digital volume control of the ADC outputs in the AIF1 signal paths is provided using the registers described in the "Digital Volume and Filter Control" section.

The outputs of the ADCs can also be routed, in a limited number of configurations, to the digital mixing output bus, via the digital sidetone signal paths. See "Digital Mixing" for further details.

Digital volume control of the ADC outputs in the digital sidetone signal paths is provided using the registers described in the "Digital Mixing" section.

ADC CLOCKING CONTROL

Clocking for the ADCs is derived from SYSCLK. The required clock is enabled when the SYSDSPCLK_ENA register is set.

The ADC clock rate is configured automatically, according to the AIFn_SR, AIFnCLK_RATE and ADC_OSR128 registers. (See "Clocking and Sample Rates" for further details of the system clocks and control registers.)

When AIF1CLK is selected as the SYSCLK source (SYSCLK_SRC = 0), then the ADC clocking is controlled by the AIF1_SR and AIF1CLK_RATE registers.

When AIF2CLK is selected as the SYSCLK source (SYSCLK_SRC = 1), then the ADC clocking is controlled by the AIF2_SR and AIF2CLK_RATE registers.

The supported ADC clocking configurations are described in Table 14(for ADC_OSR128=1) and Table 15(for ADC_OSR128=0). The ADC_OSR128 bit is set by default, giving best audio performance.

| SAMPLE | SYSCLK RATE (AIFnCLK / fs ratio) | | | | | | | |

Table 15 ADC Clocking - ADC_OSR128 = 0

The clocking requirements in Table 14 and Table 15 are only applicable to the AIF*n*CLK that is selected as the SYSCLK source. Note that both clocks (AIF1CLK and AIF2CLK) must satisfy the requirements noted in the "Clocking and Sample Rates" section.

The applicable clocks (SYSCLK, and AIF1CLK or AIF2CLK) must be present and enabled when using the Analogue to Digital Converters (ADCs).

PD, August 2014, Rev 4.2

DIGITAL CORE ARCHITECTURE

The WM1811A Digital Core provides an extensive set of mixing and signal processing features. The Digital Core Architecture is illustrated in Figure 17, which also identifies the datasheet sections applicable to each portion of the Digital Core.

The digital audio interfaces AIF1 and AIF2 each support one stereo pair of input and output signal paths through the WM1811A DSP functions. The signal mixing for the AIF1 and AIF2 output paths is described in "Audio Interface 1 (AIF1) Output Digital Mixing" and "Audio Interface 2 (AIF2) Output Digital Mixing" respectively.

A digital mixing path from the ADCs or Digital Microphones to the DAC and AIF2 output paths provides a high quality sidetone for voice calls or other applications. The sidetone filter and volume controls are described in "Digital Sidetone Volume and Filter Control".

Each of the DACs has a dedicated mixer for controlling the signal paths to that DAC. The configuration of these signal paths is described in "DAC Output Digital Mixing". A similar pair of mixers is provided for controlling the signal paths to the AIF2 output channels, as described in "Audio Interface 2 (AIF2) Output Digital Mixing".

The DAC and AIF2 output signal paths are each provided with digital volume control andsoft mute / un-mute features. The associated controls are defined in the "Digital Volume (DAC and AIF2 Output Paths)" and the "Digital Volume Soft Mute and Soft Un-Mute" sections.

Digital signal processing can be applied to the input and output signal paths. The available features include 5-band equalization (EQ), 3D stereo expansion and dynamic range control (DRC).

The EQ provides the capability to tailor the audio path according to the frequency characteristics of an earpiece or loudspeaker, and/or according to user preferences. The EQ controls are described in "ReTune[™] Mobile Parametric Equalizer (EQ)".The DRC provides adaptive signal level control to improve the handling of unpredictable signal levels and to improve intelligibility in the presence of transients and impulsive noises. The DRC controls are described in "Dynamic Range Control (DRC)". 3D stereo expansion provides a stereo enhancement effect; the depth of the effect is programmable, as described in "3D Stereo Expansion".

The input signal paths are also equipped with digital volume control and soft mute / un-mute control; see "Digital Volume and Filter Control" for details of these features.

The output signal paths are equipped with digital volume control and a programmable high-pass filter (HPF). The Dynamic Range Control (DRC) circuit can also be applied here, with the restriction that a DRC cannot be enabled in the input and output path of one AIF channel at the same time. The AIF output volume and filter controls are described in "Digital Volume and Filter Control".

The WM1811A provides an ultrasonic mode on the output paths of AIF1, allowing high frequency signals (such as ultrasonic microphone signals) to be output. See "Ultrasonic (4FS) AIF Output Mode" for further details.

The WM1811A provides two full audio interfaces, AIF1 and AIF2. Each interface supports a number of protocols, including I²S, DSP, MSB-first left/right justified, and can operate in master or slave modes. PCM operation is supported in the DSP mode. A-law and μ -law companding are also supported. Time division multiplexing (TDM) is available to allow multiple devices to stream data simultaneously on the same bus, saving space and power.

Two-channel input and output is supported on AIF1 and on AIF2. A third interface, AIF3, is partially supported, using multiplexers to re-configure alternate connections to AIF1 or AIF2.

Signal mixing between audio interfaces is possible. The WM1811A performs stereo full-duplex sample rate conversion between the audio interfaces as required.

The audio interfaces AIF1, AIF2 and AIF3 are referenced to DBVDD1, DBVDD2 and DBVDD3 respectively; this provides additional capability to interface between different sub-systems within an application.

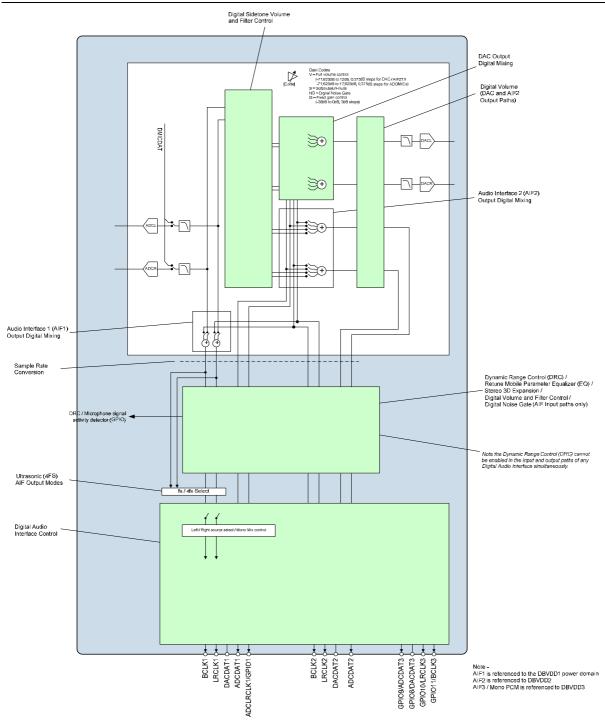

Figure 17 Digital Core Architecture

DIGITAL MIXING

This section describes the digital mixing functions of the WM1811A.

Digital audio mixing is provided on the AIF1 output, digital sidetone, Digital to Analogue converters(DACs) and AIF2 output paths.

The digital mixing functions and associated control registers are illustrated in Figure 18.

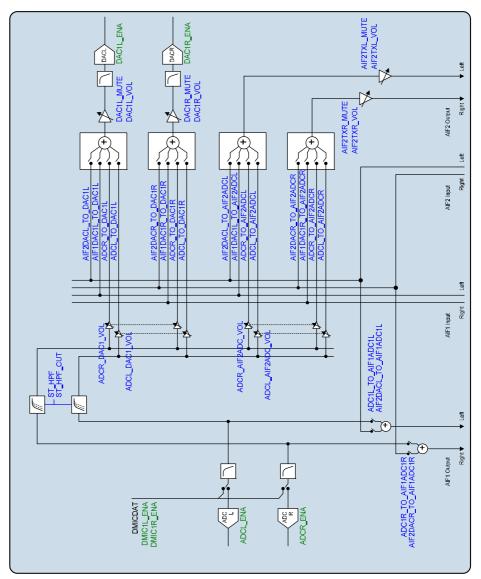

Figure 18 Digital Mixing Block Diagram

PD, August 2014, Rev 4.2

AUDIO INTERFACE 1 (AIF1) OUTPUT DIGITAL MIXING

There are two digital mixers associated with the AIF1 output channels. The inputs to each AIF1 mixer comprise signals from the ADC / Digital Microphone inputs and from AIF2.

Note that the Left/Right channels of AIF1 can be inverted or interchanged if required; see "Digital Audio Interface Control".

The AIF1 Left output channel is derived from the ADCL / DMIC (Left) and AIF2 (Left) inputs.The ADCL / DMIC (Left) path is enabled by ADC1L_TO_AIF1ADC1L, whilst the AIF2 (Left) path is enabled by AIF2DACL_TO_AIF1ADC1L.

The AIF1 Right output channel is derived from the ADCR / DMIC (Right) and AIF2 (Right) inputs. The ADCR / DMIC (Right) path is enabled by ADC1R_TO_AIF1ADC1R, whilst the AIF2 (Right) path is enabled by AIF2DACR_TO_AIF1ADC1R.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---|-----|---------------------------|---------|---|
| R1542 (0606h) AIF1 ADC1 Left Mixer Routing | 1 | ADC1L_TO_AIF 1ADC1L | 0 | Enable ADCL / DMIC (Left) to AIF1 (Left) output 0 = Disabled 1 = Enabled |

| | 0 | AIF2DACR_TO_ AIF1ADC1R | 0 | Enable AIF2 (Right) to AIF1 (Right) output 0 = Disabled 1 = Enabled |

The AIF1 output mixer controls are defined in Table 16

Table 16 AIF1 Output Mixing

DIGITAL SIDETONE VOLUME AND FILTER CONTROL

There are two digital sidetone signal paths, STL and STR.

The STL source is either ADCL or DMICDAT (Left). The Left ADC data will be selected if the corresponding ADC is enabled (ie. if ADCL_ENA = 1). The Left digital microphone (DMIC) data will be selected if the corresponding ADC is disabled (ie. if ADCL_ENA = 0).

The STR source is either ADCR or DMICDAT (Right). The Right ADC data will be selected if the corresponding ADC is enabled (ie. if ADCR_ENA = 1). The Right digital microphone (DMIC) data will be selected if the corresponding ADC is disabled (ie. if ADCR_ENA = 0).

See "Analogue to Digital Converter (ADC)" for details of the ADC control registers.

A digital volume control is provided for the digital sidetone paths. The associated register controls are described in Table 17.

A digital high-pass filter can be enabled in the sidetone paths to remove DC offsets. This filter is enabled using the ST_HPF register bit; the cut-off frequency is configured using ST_HPF_CUT. When the filter is enabled, it is enabled in both digital sidetone paths.

Note that the sidetone filter cut-off frequency scales according to the sample rate of AIF1 or AIF2. When AIF1CLK is selected as the SYSCLK source (SYSCLK_SRC = 0), then the ST_HPF cut-off frequency is scaled according to the AIF1_SR register. When AIF2CLK is selected as the SYSCLK source (SYSCLK_SRC = 1), then the ST_HPF cut-off frequency is scaled according to the AIF2_SR

The AIF2 output mixer controls are defined in Table 20.

Table 20 AIF2 Output Mixing

DIGITAL VOLUME (DAC AND AIF2 OUTPUT PATHS)

The volume level of each DAC output mixer path and each AIF2 output mixer path can be controlled digitally over a range from -71.625dB to +12dBin 0.375dB steps. The level of attenuation for an eight-bit code X is given by:

 $0.375 \times (X-192) \text{ dB for } 1 \leq X \leq 224; \qquad \text{MUTE for } X = 0; \qquad \qquad 12 \text{dB to } 224 \leq X \leq 255$

Each of the digital output mixer paths can be muted using the soft mute control bits described inTable 21. The WM1811A always applies a soft mute, where the volume is decreased gradually. The unmute behaviour is configurable, as described in the "Digital Volume Soft Mute and Soft Un-Mute" section.

The DAC1_VU and AIF2TX_VU bits control the loading of digital volume control data. When DAC1_VU is set to 0, the DAC1L_VOL or DAC1R_VOL control data will be loaded into the respective control register, but will not actually change the digital gain setting. Both left and right gain settings are updated when a 1 is written to DAC1_VU. This makes it possible to update the gain of both channels simultaneously. A similar function for AIF2TXL and AIF2TXR is controlled by the AIF2TX_VU register bit.

Table 22 DAC and AIF2 Output Digital Volume Range

PD, August 2014, Rev 4.2

DIGITAL VOLUME SOFT MUTE AND SOFT UN-MUTE

The WM1811A has a soft mute function which ensures that a gradual attenuation is applied to the DAC output mixers or AIF2 output mixers when the associated mute is asserted. The soft mute rate can be selected using the DAC_MUTERATE bit.

When a mute bit is disabled, the gain will either gradually ramp back up to the digital gain setting, or return instantly to the digital gain setting, depending on the DAC_SOFTMUTEMODE register bit. If the gradual un-mute ramp is selected (DAC_SOFTMUTEMODE = 1), then the un-mute rate is determined by the DAC_MUTERATE bit.

Note that each DAC (or AIF2 output mixer) is soft-muted by default. To play back an audio signal, the mute must first be disabled by setting the applicable mute control to 0 (seeTable 21).

Soft Mute Mode would typically be enabled (DAC_SOFTMUTEMODE = 1) when using mute during playback of audio data so that when the mute is subsequently disabled, the volume increase will not create pop noise by jumping immediately to the previous volume level (e.g. resuming playback after pausing during a track).

Soft Mute Mode would typically be disabled (DAC_SOFTMUTEMODE = 0) when un-muting at the start of a music file, in order that the first part of the track is not attenuated (e.g. when starting playback of a new track, or resuming playback after pausing between tracks).

The DAC soft-mute function is illustrated in Figure 19 for DAC1L and DAC1R. The same function is applicable to AIF2TXL and AIF2TXRalso.

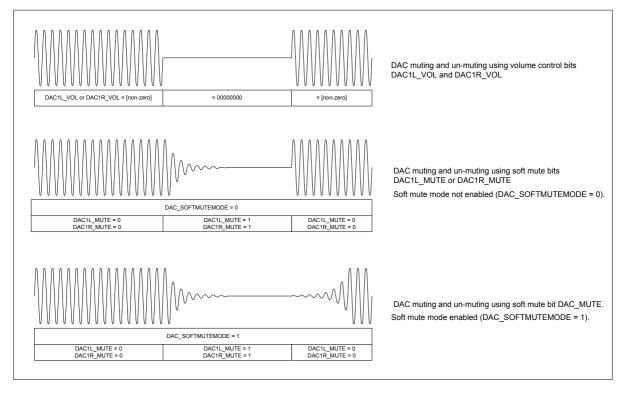

Figure 19 Digital Volume Soft Mute Control

The DAC Soft Mute register controls are defined in Table 23.

The volume ramp rate during soft mute and un-mute is controlled by the DAC_MUTERATE bit. Ramp rates of fs/32 and fs/2 are selectable. The ramp rate determines the rate at which the volume will be increased or decreased. Note that the actual ramp time depends on the extent of the difference between the muted and un-muted volume settings.

| | | | | (Note: ramp rate scales with sample rate.) |

Table 23 Digital Volume Soft-Mute Control

ULTRASONIC (4FS) AIF OUTPUT MODE

The WM1811A provides an ultrasonic mode on the output paths of the AIF1 audio interface. The ultrasonic mode enables high frequency signals (such as ultrasonic microphone signals) to be output.

Ultrasonic mode is enabled on AIF1 using the AIF1ADC_4FS register bit. When the ultrasonic mode is selected, the AIF1output sample rate is increased by a factor of 4. For example, a 48kHz sample rate will be output at 192kHz in ultrasonic mode.

Ultrasonic mode is only supported in AIF Master mode and uses the ADCLRCLK output (not the LRCLK). When ultrasonic mode is enabled, the AIF1 must be configured in Master mode, as described in "Digital Audio Interface Control".See "General Purpose Input/Output" to configure the GPIO1 pin as ADCLRCLK1.The ADCLRCLK1 rate is controlled as described in "Digital Audio Interface Control".

When ultrasonic mode is enabled, the audio band filtering and digital volume controls (see "Digital Volume and Filter Control") are bypassed on the affected output paths.

The Dynamic Range Control (DRC) function is not available on the AIF1output signal paths in ultrasonic mode. Note, however, that the DRC is still available on the AIF input paths in this case.

The ultrasonic (4FS) signal paths are illustrated in Figure 20. The AIF1ADC_4FS register bit is defined in Table 24.

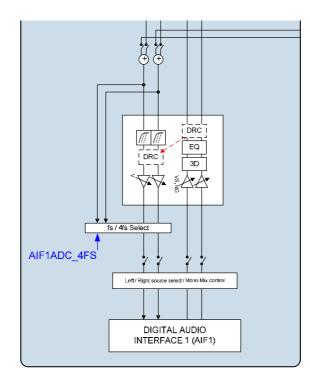

Figure 20 Ultrasonic (4FS) Signal Paths

Table 24 Ultrasonic (4FS) Mode Control

DYNAMIC RANGE CONTROL (DRC)

The Dynamic Range Control (DRC) is a circuit which can be enabled in the digital playback or digital record paths of the WM1811A audio interfaces. The function of the DRC is to adjust the signal gain in conditions where the input amplitude is unknown or varies over a wide range, e.g. when recording from microphones built into a handheld system.

The DRC can apply Compression and Automatic Level Control to the signal path. It incorporates 'anticlip' and 'quick release' features for handling transients in order to improve intelligibility in the presence of loud impulsive noises.

The DRC also incorporates a Noise Gate function, which provides additional attenuation of very lowlevel input signals. This means that the signal path is quiet when no signal is present, giving an improvement in background noise level under these conditions.

The WM1811A provides two stereo Dynamic Range Controllers (DRCs); these are associated with AIF1 and AIF2 respectively. Each DRC can be enabled either in the DAC playback (AIF input) path or in the ADC record (AIF output) path, as described in the "Digital Core Architecture" section.

The DRCs are enabled in the DAC or ADCs audio signal paths using the register bits described in Table 25. Note that enabling any DRC in the DAC and ADC paths simultaneously is an invalid selection.

When the DRC is enabled in any of the ADC (digital record) paths, the associated High Pass Filter (HPF) must be enabled also; this ensures that DC offsets are removed prior to the DRC processing. The output path HPF control registers are described in Table 37 (for AIF1 output paths) and Table 45 (for AIF2 output paths). These are described in the "Digital Volume and Filter Control" section.

Note that, when ultrasonic (4FS) mode is selected on AIF1, then the DRC function is bypassed on the respective ADC (output) signal paths. The DRC may still be selected on the AIF1DAC (input) signal paths.

Table 25 DRC Enable

The following description of the DRC is applicable to both DRCs. The associated register control fields are described inTable 27 and Table 28 for the respective DRCs.

Note that, where the following description refers to register names, the generic prefix [DRC] is quoted:

- For the DRC associated with AIF1, [DRC] = AIF1DRC1.
- For the DRC associated with AIF2, [DRC] = AIF2DRC.

DRC COMPRESSION / EXPANSION /LIMITING

The DRC supports two different compression regions, separated by a "Knee" at a specific input amplitude. In the region above the knee, the compression slope [DRC]_HI_COMP applies; in the region below the knee, the compression slope [DRC]_LO_COMP applies.

The DRC also supports a noise gate region, where low-level input signals are heavily attenuated. This function can be enabled or disabled according to the application requirements. The DRC response in this region is defined by the expansion slope [DRC]_NG_EXP.

For additional attenuation of signals in the noise gate region, an additional "knee" can be defined (shown as "Knee2" in Figure 21). When this knee is enabled, this introduces an infinitely steep dropoff in the DRC response pattern between the [DRC]_LO_COMP and [DRC]_NG_EXP regions.

The overall DRC compression characteristic in "steady state" (i.e. where the input amplitude is nearconstant) is illustrated in Figure 21.

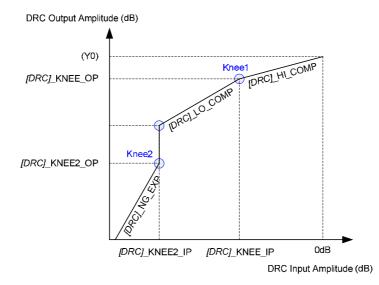

Figure 21 DRC Response Characteristic

The slope of the DRC response is determined by register fields [DRC]_HI_COMP and [DRC]_LO_COMP. A slope of 1 indicates constant gain in this region. A slope less than 1 represents compression (i.e. a change in input amplitude produces only a smaller change in output amplitude). A slope of 0 indicates that the target output amplitude is the same across a range of input amplitudes; this is infinite compression.

When the noise gate is enabled, the DRC response in this region is determined by the [DRC]_NG_EXP register. A slope of 1 indicates constant gain in this region. A slope greater than 1 represents expansion (ie. a change in input amplitude produces a larger change in output amplitude).

When the DRC_KNEE2_OP knee is enabled ("Knee2" in Figure 21), this introduces the vertical line in the response pattern illustrated, resulting in infinitely steep attenuation at this point in the response.

The DRC parameters are listed in Table 26.

| REF | PARAMETER | DESCRIPTION |
|-----|----------------|-------------------------------|
| 1 | [DRC]_KNEE_IP | Input level at Knee1 (dB) |
| 2 | [DRC]_KNEE_OP | Output level at Knee2 (dB) |
| 3 | [DRC]_HI_COMP | Compression ratio above Knee1 |
| 4 | [DRC]_LO_COMP | Compression ratio below Knee1 |
| 5 | [DRC]_KNEE2_IP | Input level at Knee2 (dB) |
| 6 | [DRC]_NG_EXP | Expansion ratio below Knee2 |
| 7 | [DRC]_KNEE2_OP | Output level at Knee2 (dB) |

 Table 26 DRC Response Parameters

The noise gate is enabled when the *[DRC]_*NG_ENA register is set. When the noise gate is not enabled, parameters 5, 6, 7 above are ignored, and the *[DRC]_*LO_COMP slope applies to all input signal levels below Knee1.

The DRC_KNEE2_OP knee is enabled when the [DRC]_KNEE2_OP_ENA register is set. When this bit is not set, then parameter 7 above is ignored, and the Knee2 position always coincides with the low end of the [DRC]_LO_COMP region.

The "Knee1" point in Figure 21 is determined by register fields [DRC]_KNEE_IP and [DRC]_KNEE_OP.

Parameter Y0, the output level for a 0dB input, is not specified directly, but can be calculated from the other parameters, using the equation:

```
Y0 = [DRC]_KNEE_OP - ([DRC]_KNEE_IP * [DRC]_HI_COMP)
```

GAIN LIMITS

The minimum and maximum gain applied by the DRC is set by register fields [*DRC*]_MINGAIN, [*DRC*]_MAXGAIN and [*DRC*]_NG_MINGAIN. These limits can be used to alter the DRC response from that illustrated in Figure 21. If the range between maximum and minimum gain is reduced, then the extent of the dynamic range control is reduced.

The minimum gain in the Compression regions of the DRC response is set by [*DRC*]_MINGAIN. The minimum gain in the Noise Gate region is set by [*DRC*]_NG_MINGAIN. The minimum gain limit prevents excessive attenuation of the signal path.

The maximum gain limit set by [DRC]_MAXGAIN prevents quiet signals (or silence) from being excessively amplified.

DYNAMIC CHARACTERISTICS

The dynamic behaviour determines how quickly the DRC responds to changing signal levels. Note that the DRC responds to the average (RMS) signal amplitude over a period of time.

The *[DRC]_*ATK determines how quickly the DRC gain decreases when the signal amplitude is high. The *[DRC]_*DCY determines how quickly the DRC gain increases when the signal amplitude is low.

These register fields are described in Table 27 and Table 28. Note that the register defaults are suitable for general purpose microphone use.

ANTI-CLIP CONTROL

The DRC includes an Anti-Clip feature to avoid signal clipping when the input amplitude rises very quickly. This feature uses a feed-forward technique for early detection of a rising signal level. Signal clipping is avoided by dynamically increasing the gain attack rate when required. The Anti-Clip feature is enabled using the *[DRC]_ANTICLIP* bit.

Note that the feed-forward processing increases the latency in the input signal path.

Note that the Anti-Clip feature operates entirely in the digital domain. It cannot be used to prevent signal clipping in the analogue domain nor in the source signal. Analogue clipping can only be prevented by reducing the analogue signal gain or by adjusting the source signal.

Note that the Anti-Clip feature should not be enabled at the same time as the Quick Release feature (described below) on the same DRC.

QUICK RELEASE CONTROL

The DRC includes a Quick-Release feature to handle short transient peaks that are not related to the intended source signal. For example, in handheld microphone recording, transient signal peaks sometimes occur due to user handling, key presses or accidental tapping against the microphone. The Quick Release feature ensures that these transients do not cause the intended signal to be masked by the longer time constants of [DRC]_DCY.

The Quick-Release feature is enabled by setting the [*DRC*]_QR bit. When this bit is enabled, the DRC measures the crest factor (peak to RMS ratio) of the input signal. A high crest factor is indicative of a transient peak that may not be related to the intended source signal. If the crest factor exceeds the level set by [*DRC*]_QR_THR, then the normal decay rate ([*DRC*]_DCY) is ignored and a faster decay rate ([*DRC*]_QR_DCY) is used instead.

Note that the Quick Release feature should not be enabled at the same time as the Anti-Clip feature (described above) on the same DRC.

SIGNAL ACTIVITY DETECT

The DRC incorporates a configurable signal detect function, allowing the signal level at the DRC input to be monitored and to be used to trigger other events. This can be used to detect the presence of a microphone signal on an ADC or digital mic channel, or can be used to detect an audio signal received over the digital audio interface.

The Peak signal level or the RMS signal level of the DRC input can be selected as the detection threshold. When the threshold condition is exceeded, an interrupt or GPIO output can be generated. See "General Purpose Input/Output" for a full description of the applicable control fields.

DRC REGISTER CONTROLS

The AIF1DRC control registers are described in Table 27.

The AIF2DRC control registers are described in Table 28.

Table 28 AIF2 DRC Controls

RETUNE[™] MOBILE PARAMETRIC EQUALIZER (EQ)

The ReTune[™] Mobile Parametric EQ is a circuit which can be enabled in the digital playback path of the WM1811A audio interfaces. The function of the EQ is to adjust the frequency characteristic of the output in order to compensate for unwanted frequency characteristics in the loudspeaker (or other output transducer). It can also be used to tailor the response according to user preferences, for example to accentuate or attenuate specific frequency bands to emulate different sound profiles or environments e.g. concert hall, rock etc.

The WM1811A provides two stereo EQ circuits; these are associated with AIF1 and AIF2 respectively. The EQ is enabled in these signal paths using the register bits described in Table 29.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|--|-----|---------------------|---------|--|
| R1152 (0480h) AIF1 DAC1 EQ Gains (1) | 0 | AIF1DAC1_EQ_E NA | 0 | Enable EQ in AIF1DAC playback path 0 = Disabled 1 = Enabled |
| R1408 (0580h) AIF2 EQ Gains (1) | 0 | AIF2DAC_EQ_EN A | 0 | Enable EQ in AIF2DAC playback path 0 = Disabled 1 = Enabled |

Table 29 ReTune[™] Mobile Parametric EQ Enable

The following description of the EQ is applicable to both EQ circuits. The associated register control fields are described in Table 31 and Table 32 for the respective EQs. The EQ provides selective control of 5 frequency bands as described below.

The low frequency band (Band 1) filter can be configured either as a peak filter or a shelving filter. When configured as a shelving filter, is provides adjustable gain below the Band 1 cut-off frequency. As a peak filter, it provides adjustable gain within a defined frequency band that is centred on the Band 1 frequency.

The mid frequency bands (Band 2, Band 3, Band 4) filters are peak filters, which provide adjustable gain around the respective centre frequency.

The high frequency band (Band 5) filter is a shelving filter, which provides adjustable gain above the Band 5 cut-off frequency.

The EQ can be configured to operate in two modes - "Default" mode or "ReTune[™] Mobile" mode.The associated register control fields are described in Table 31 and Table 32 for the respective EQs.

DEFAULT MODE (5-BAND PARAMETRIC EQ)

In default mode, the cut-off/centre frequencies are fixed as per Table 30. The filter bandwidths are also fixed in default mode. The gain of the individual bands (-12dB to +12dB) can be controlled as described in Table 31.

The cut-off / centre frequencies noted in Table 30 are applicable to a sample rate of 48kHz. When using other sample rates, these frequencies will be scaled in proportion to the selected sample rate for the associated Audio Interface (AIF1 or AIF2).

If AIF1 and AIF2 are operating at different sample rates, then the cut-off / centre frequencies will be different for the two interfaces. Note that the frequencies can be set to other values by using the features described in "ReTune[™] Mobile Mode".

| EQ BAND | CUT-OFF/CENTRE FREQUENCY |
|---------|--------------------------|
| 1 | 100 Hz |
| 2 | 300 Hz |
| 3 | 875 Hz |
| 4 | 2400 Hz |
| 5 | 6900 Hz |

Table 33 EQ Gain Control Range

RETUNE[™] MOBILE MODE

ReTune[™] Mobile mode provides a comprehensive facility for the user to define the cut-off/centre frequencies and filter bandwidth for each EQ band, in addition to the gain controls already described. This enables the EQ to be accurately customised for a specific transducer characteristic or desired sound profile.

The EQ enable and EQ gain controls are the same as defined for the default mode. The additional coefficients used in ReTune[™] Mobile mode are held in registers R1154 to R1172 for AIF1, and registers R1410 to R1428 for AIF2. These coefficients are derived using tools provided in Wolfson's WISCE[™] evaluation board control software.

Please contact your local Wolfson representative for more details.

Note that the WM1811A audio interfaces may operate at different sample rates concurrently. The EQ settings for each interface must be programmed relative to the applicable sample rate of the corresponding audio interface. If the audio interface sample rate is changed, then different EQ register settings will be required to achieve a given EQ response.

EQ FILTER CHARACTERISTICS

The filter characteristics for each frequency band are shown in Figure 22 to Figure 26. These figures show the frequency response for all available gain settings, using default cut-off/centre frequencies and bandwidth. Note that EQ Band 1 can also be configured as a Peak Filter if required.

3D STEREO EXPANSION

The 3D Stereo Expansion is an audio enhancement feature which can be enabled in the digital playback path of the WM1811A audio interfaces. This feature uses configurable cross-talk mechanisms to adjust the depth or width of the stereo audio.

The WM1811A provides two 3D Stereo Expansion circuits; these are associated with AIF1 and AIF2 respectively. The 3D Stereo Expansion is enabled and controlled in these signal paths using the register bits described in Table 34.

Table 34 3D Stereo Expansion Control

DIGITAL VOLUME AND FILTER CONTROL

This section describes the digital volume and filter controls of the WM1811A AIF paths.

Digital volume control and High Pass Filter (HPF) control is provided on the AIF1 and AIF2 output (digital record) paths.

Note that, when ultrasonic (4FS) mode is selected on AIF1, then the digital volume control and high pass filter (HPF) control are bypassed on the respective ADC (output) signal paths.

Digital volume, soft-mute and mono mix control is provided on the AIF1 and AIF2 input (digital playback) paths. A configurable noise gate function is available on each of the digital playback paths.

AIF1 - OUTPUT PATH VOLUME CONTROL

A digital volume control is provided on the AIF1 output signal paths, allowing attenuation in the range - 71.625dB to +17.625dB in 0.375dB steps. The level of attenuation for an eight-bit code X is given by:

 $0.375 \times (X-192) dB$ for $1 \le X \le 239$; MUTE for X = 0 +17.625dB for $239 \le X \le 255$

The AIF1ADC1_VU bits control the loading of digital volume control data. When this bit is set to 0, the AIF1ADC1L_VOL and AIF1ADC1R_VOL control data will be loaded into the respective control register, but will not actually change the digital gain setting.

The AIF1ADC1L_VOL and AIF1ADC1R_VOL gain settings are updated when a 1 is written to AIF1ADC1_VU. This makes it possible to update the gain of left and right channels simultaneously.

Table 36 AIF1 Output Path Digital Volume Range

AIF1 - OUTPUT PATH HIGH PASS FILTER

A digital high-pass filter can be enabled in the AIF1 output paths to remove DC offsets. This filter is enabled independently on each output channel using the register bits described in Table 37.

The HPF cut-off frequency for the AIF1 channels is set using AIF1ADC1_HPF_CUT.

In hi-fi mode, the high pass filter is optimised for removing DC offsets without degrading the bass response and has a cut-off frequency of 3.7Hz when the sample rate (fs) = 44.1kHz.

In voice modes, the high pass filter is optimised for voice communication; it is recommended to set the cut-off frequency below 300Hz.

Note that the cut-off frequencies scale with the AIF1 sample rate. (The AIF1 sample rate is set using the AIF1_SR register, as described in the "Clocking and Sample Rates" section.) See Table 38 for the HPF cut-off frequencies at all supported sample rates.

Table 38 AIF1 Output Path High Pass Filter Cut-Off Frequencies

AIF1 - INPUT PATH VOLUME CONTROL

A digital volume control is provided on the AIF1 input signal paths, allowing attenuation in the range - 71.625dB to 0dB in 0.375dB steps. The level of attenuation for an eight-bit code X is given by:

 $0.375 \times (X-192) \text{ dB for } 1 \leq X \leq 192; \qquad \text{MUTE for } X = 0 \qquad \text{0dB for } 192 \leq X \leq 255$

The AIF1DAC1_VU bits control the loading of digital volume control data. When this bit is set to 0, the AIF1DAC1L_VOL and AIF1DAC1R_VOLcontrol data will be loaded into the respective control register, but will not actually change the digital gain setting.

The AIF1DAC1L_VOL and AIF1DAC1R_VOLgain settings are updated when a 1 is written to AIF1DAC1_VU. This makes it possible to update the gain of left and right channels simultaneously.

Note that a digital gain function is also available at the audio interface input, to boost the DAC volume when a small signal is received on DACDAT1. See "Digital Audio Interface Control" for further details.

Digital volume control is also possible within the digital core functions, after the audio signal has passed through the DAC output digital mixers or AIF2 output digital mixers. See "Digital Mixing" for further details.

Table 40 AIF1 Input Path Digital Volume Range

AIF1 - INPUT PATH SOFT MUTE CONTROL

The WM1811A provides a soft mute function for the AIF1 input paths. When the mute function is selected, the WM1811A gradually attenuates the associated signal paths until the path is entirely muted.

When the mute function is de-selected, the gain will either return instantly to the digital gain setting, or will gradually ramp back to the digital gain setting, depending on the AIF1DAC1_UNMUTE_RAMP register field.

The mute and un-mute ramp rate is selectable between two different rates.

The AIF1 input paths are soft-muted by default. To play back an audio signal, the soft-mute must first be de-selected by setting AIF1DAC1_MUTE = 0.

The soft un-mute would typically be used during playback of audio data so that when the Mute is subsequently disabled, a smooth transition is scheduled to the previous volume level and pop noise is avoided. This is desirable when resuming playback after pausing during a track.

The soft un-mute would typically not be required when un-muting at the start of a music file, in order that the first part of the music track is not attenuated. The instant un-mute behaviour is desirable in this case, when starting playback of a new track. See "Digital Volume Soft Mute and Soft Un-Mute" (Figure 19) for an illustration of the soft mute function.

| | | | | 1 = Unmuting the AIF1DAC path (AIF1DAC1_MUTE=0) will cause a gradual volume ramp up to the AIF1DAC1L_VOL and AIF1DAC1R_VOL settings. |

Table 41 AIF1 Input Path Soft Mute Control

AIF1 - INPUT PATH NOISE GATE CONTROL

The WM1811A provides a digital noise gate function for the AIF1 input paths. The noise gate ensures best noise performance when the signal path is idle. When the noise gate is enabled, and the signal level is below the noise gate threshold, then the noise gate is activated, causing the signal path to be muted.

The AIF1 input path noise gate is enabled using the AIF1DAC1_NG_ENA register.

The noise gate threshold (the signal level below which the noise gate is activated) is set using AIF1DAC1_NG_THR.

To prevent erroneous triggering, a time delay is applied before the gate is activated; the signal path is only muted when the signal level stays below the threshold for longer than 'hold time', determined by the AIF1DAC1_NG_HLD register.

When the noise gate is activated, the WM1811A gradually attenuates the AIF1 input signal paths until each is entirely muted. When the signal level increases, and the noise gate is de-activated, the gain will return to the AIF1DAC1L_VOL and AIF1DAC1R_VOL digital gain settings. The un-mute behaviour can be immediate or gradual; this is determined by the AIF1DAC1_MUTERATE and AIF1DAC1_UNMUTE_RAMP registers described in Table 41.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|--|-----|------------------------------|---------|--|

Table 42 AIF1 Input Path Noise Gate Control

AIF1 - INPUT PATH MONO MIX CONTROL

A digital mono mix can be selected on the AIF1 input channels. The mono mix is generated as the sum of the Left and Right AIF channel data. When the mono mix function is enabled, the combined mono signal is applied to the Left channel and the Right channel of the AIF1 signal processing and digital mixing paths. To prevent clipping, 6dB attenuation is applied to the mono mix.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---|-----|-------------------|---------|--|
| R1056 (0420h) AIF1 DAC1 Filters (1) | 7 | AIF1DAC1_ MONO | 0 | AIF1DAC input path Mono Mix Control 0 = Disabled 1 = Enabled |

Table 43 AIF1 Input Path Mono Mix Control

AIF2 - OUTPUT PATH VOLUME CONTROL

A digital volume control is provided on the AIF2 output signal paths, allowing attenuation in the range - 71.625dB to +17.625dB in 0.375dB steps. The level of attenuation for an eight-bit code X is given by:

 $0.375 \times (X-192) \ dB \ \ for \ \ 1 \leq X \leq 239; \qquad MUTE \ \ for \ \ X = 0 \qquad +17.625 dB \ for \ \ 239 \leq X \leq 255$

The AIF2ADC_VU bits control the loading of digital volume control data. When this bit is set to 0, the AIF2ADCL_VOL and AIF2ADCR_VOL control data will be loaded into the respective control register, but will not actually change the digital gain setting.

The AIF2ADCL_VOL and AIF2ADCR_VOL gain settings are updated when a 1 is written to AIF2ADC VU. This makes it possible to update the gain of left and right channels simultaneously.

Digital volume control is also possible within the digital core functions, after the audio signal has passed through the AIF2 output digital mixers. See "Digital Mixing" for further details.

Table 44 AIF2 Output Path Volume Control

AIF2 - OUTPUT PATH HIGH PASS FILTER

A digital high-pass filter can be enabled in the AIF2 output paths to remove DC offsets. This filter is enabled independently on each output channel using the register bits described inTable 45.

The HPF cut-off frequency for the AIF2 channels is set using AIF2ADC_HPF_CUT.

In hi-fi mode, the high pass filter is optimised for removing DC offsets without degrading the bass response and has a cut-off frequency of 3.7Hz when the sample rate (fs) = 44.1kHz.

In voice modes, the high pass filter is optimised for voice communication; it is recommended to set the cut-off frequency below 300Hz.

Note that the cut-off frequencies scale with the AIF2 sample rate. (The AIF2 sample rate is set using the AIF2_SR register, as described in the "Clocking and Sample Rates" section.) See Table 38 for the HPF cut-off frequencies at all supported sample rates.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

Table 45 AIF2 Output Path High Pass Filter

AIF2 - INPUT PATH VOLUME CONTROL

A digital volume control is provided on the AIF2 input signal paths, allowing attenuation in the range - 71.625dB to 0dB in 0.375dB steps. The level of attenuation for an eight-bit code X is given by:

 $0.375 \times (X\text{-}192) \text{ dB for } 1 \leq X \leq 192; \qquad \text{MUTE for } X = 0 \qquad \text{0dB for } 192 \leq X \leq 255$

The AIF2DAC_VU bits control the loading of digital volume control data. When this bit is set to 0, the AIF2DACL_VOL and AIF2DACR_VOL control data will be loaded into the respective control register, but will not actually change the digital gain setting.

The AIF2DACL_VOL and AIF2DACR_VOL gain settings are updated when a 1 is written to AIF2DAC_VU. This makes it possible to update the gain of left and right channels simultaneously.

Note that a digital gain function is also available at the audio interface input, to boost the DAC volume when a small signal is received on DACDAT2. See "Digital Audio Interface Control" for further details.

Digital volume control is also possible within the digital core functions, after the audio signal has passed through the DAC output digital mixers or AIF2 output digital mixers. See "Digital Mixing" for further details.

Table 46 AIF2 Input Path Volume Control

PD, August 2014, Rev 4.2

AIF2 - INPUT PATH SOFT MUTE CONTROL

The WM1811A provides a soft mute function for the AIF2input paths. When the mute function is selected, the WM1811A gradually attenuates the associated signal paths until the path is entirely muted.

When the mute function is de-selected, the gain will either return instantly to the digital gain setting, or will gradually ramp back to the digital gain setting, depending on the AIF2DAC_UNMUTE_RAMP register field.

The mute and un-mute ramp rate is selectable between two different rates.

The AIF2input paths are soft-muted by default. To play back an audio signal, the soft-mute must first be de-selected by setting AIF2DAC_MUTE = 0.

The soft un-mute would typically be used during playback of audio data so that when the Mute is subsequently disabled, a smooth transition is scheduled to the previous volume level and pop noise is avoided. This is desirable when resuming playback after pausing during a track.

The soft un-mute would typically not be required when un-muting at the start of a music file, in order that the first part of the music track is not attenuated. The instant un-mute behaviour is desirable in this case, when starting playback of a new track. See "Digital Volume Soft Mute and Soft Un-Mute" (Figure 19) for an illustration of the soft mute function.

| | | | | 1 = Unmuting the AIF2DAC path (AIF2DAC_MUTE=0) will cause a gradual volume ramp up to the AIF2DACL_VOL and AIF2DACR_VOL settings. |

Table 47 AIF2 Input Path Soft Mute Control

AIF2 - INPUT PATH NOISE GATE CONTROL

The WM1811A provides a digital noise gate function for the AIF2 input paths. The noise gate ensures best noise performance when the signal path is idle. When the noise gate is enabled, and the signal level is below the noise gate threshold, then the noise gate is activated, causing the signal path to be muted.

The AIF2 input path noise gate is enabled using the AIF2DAC_NG_ENA register.

The noise gate threshold (the signal level below which the noise gate is activated) is set using AIF2DAC_NG_THR.

To prevent erroneous triggering, a time delay is applied before the gate is activated; the signal path is only muted when the signal level stays below the threshold for longer than 'hold time', determined by the AIF2DAC_NG_HLD register.

When the noise gate is activated, the WM1811A gradually attenuates the AIF2 input signal paths until each is entirely muted. When the signal level increases, and the noise gate is de-activated, the gain will return to the AIF2DACL_VOL and AIF2DACR_VOL digital gain settings. The un-mute behaviour can be immediate or gradual; this is determined by the AIF2DAC_MUTERATE and AIF2DAC_UNMUTE_RAMP registers described in Table 47.

Table 48 AIF2 Input Path Noise Gate Control

AIF2- INPUT PATH MONO MIX CONTROL

A digital mono mix can be selected on theAIF2input channels. The mono mix is generated as the sum of the Left and Right AIF channel data. When the mono mix function is enabled, the combined mono signal is applied to the Left channel and the Right channel of the AIF2 signal processing and digital mixing paths. To prevent clipping, 6dB attenuation is applied to the mono mix.

Table 49 AIF2 Input Path Mono Mix Control

DIGITAL TO ANALOGUE CONVERTER (DAC)

The WM1811A DACs receive digital input data from the DAC mixers - see "Digital Mixing". The digital audio data is converted to oversampled bit streams in the on-chip, true 24-bit digital interpolation filters. The bitstream data enters two multi-bit, sigma-delta DACs, which convert them to high quality analogue audio signals. The multi-bit DAC architecture reduces high frequency noise and sensitivity to clock jitter. It also uses a Dynamic Element Matching technique for high linearity and low distortion.

A high performance mode of DAC operation can be selected by setting the DAC_OSR128 bit - see "Clocking and Sample Rates" for details.

The analogue outputs from the DACs can be mixed with analogue line/mic inputs using the line output mixers MIXOUTL / MIXOUTR and the speaker output mixers SPKMIXL / SPKMIXR.

The DACs are enabled using the register bits defined in Table 50.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

| | | А | | 0 = Disabled |
| | | | | 1 = Enabled |

Note that the DAC clock must be enabled whenever the DACs are enabled.

Table 50 DAC Enable Control

DAC CLOCKING CONTROL

Clocking for the DACs is derived from SYSCLK.The required clock is enabled when the SYSDSPCLK_ENA register is set.

The DAC clock rate is configured automatically, according to the AIFn_SR, AIFnCLK_RATE and DAC_OSR128 registers. (See "Clocking and Sample Rates" for further details of the system clocks and control registers.)

When AIF1CLK is selected as the SYSCLK source (SYSCLK_SRC = 0), then the DAC clocking is controlled by the AIF1_SR and AIF1CLK_RATE registers.

When AIF2CLK is selected as the SYSCLK source (SYSCLK_SRC = 1), then the DAC clocking is controlled by the AIF2_SR and AIF2CLK_RATE registers.

The supported DAC clocking configurations are described in Table 51 (for DAC_OSR128=0) and Table 52 (for DAC_OSR128=1). Under default conditions, the DAC_OSR128 bit is not set.

Table 52 DAC Clocking - DAC_OSR128 = 1

Note 1 - These clocking rates are only supported for 'simple' DAC-only playback modes, under the following conditions:

- AIF input is enabled on a single interface (AIF1 or AIF2) only, or is enabled on AIF1 and AIF2 simultaneously provided AIF1 and AIF2 are synchronised (ie. AIF1CLK_SRC = AIF2CLK_SRC)
- All AIF output paths are disabled
- All DSP functions (ReTune[™] Mobile Parametric Equaliser, 3D stereo expansion and Dynamic Range Control) are disabled

The clocking requirements in Table 51 and Table 52 are only applicable to the AIF*n*CLK that is selected as the SYSCLK source. Note that both clocks (AIF1CLK and AIF2CLK) must satisfy the requirements noted in the "Clocking and Sample Rates" section.

The applicable clocks (SYSCLK, and AIF1CLK or AIF2CLK) must be present and enabled when using the Digital to Analogue Converters (DACs).

Note that the presence of a suitable clock is automatically detected by the WM1811A; if the clock signal is absent, then any speaker or earpiece output driver(s) associated with the DAC signal paths will be disabled. (This is applicable to the SPKOUTL, SPKOUTR and HPOUT2 outputs only, whenever one or more DAC is routed to these output drivers.)

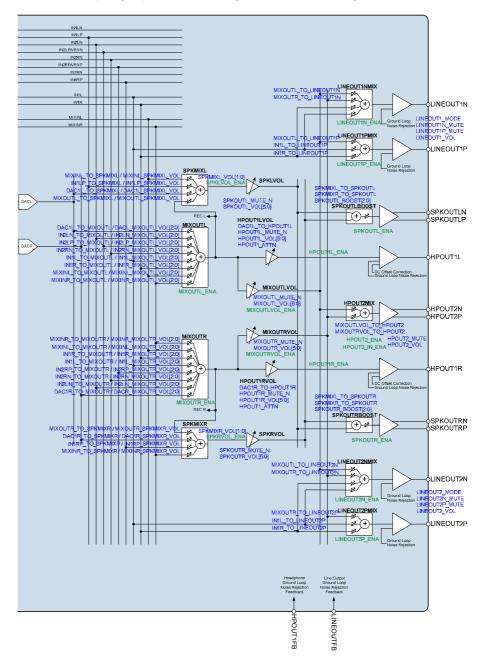

PD, August 2014, Rev 4.2

ANALOGUE OUTPUT SIGNAL PATH

The WM1811A output routing and mixers provide a high degree of flexibility, allowing operation of many simultaneous signal paths through the device to a variety of analogue outputs. The outputs include a ground referenced headphone driver, two Class D loudspeaker drivers, an ear speaker driver and four highly flexible line drivers. See "Analogue Outputs" for further details of these outputs.

The WM1811A output signal paths and control registers are illustrated in Figure 27.

OUTPUT SIGNAL PATHS ENABLE

The output mixers and drivers can be independently enabled and disabled as described in Table 53.

The supply rails for headphone outputs HPOUT1L and HPOUT1R are generated using an integrated dual-mode Charge Pump, which must be enabled whenever the headphone outputs are used. See the "Charge Pump" section for details on enabling and configuring this circuit.

Note that the Headphone Outputs are also controlled by fields located within Register R96, which provide suppression of pops & clicks when enabling and disabling the HPOUT1L and HPOUT1R signal paths. These registers are described in the following "Headphone Signal Paths Enable" section.

For normal operation of the output signal paths, the reference voltage VMID and the bias current must also be enabled. See "Reference Voltages and Master Bias" for details of the associated controls VMID_SEL and BIAS_ENA.

Table 53 Output Signal Paths Enable

HEADPHONE SIGNAL PATHS ENABLE

The HPOUT1L and HPOUT1R output paths can be actively discharged to AGND through internal resistors if desired. This is desirable at start-up in order to achieve a known output stage condition prior to enabling the VMID reference voltage. This is also desirable in shutdown to prevent the external connections from being affected by the internal circuits. The HPOUT1L and HPOUT1R outputs are shorted to AGND by default; the short circuit is removed on each of these paths by setting the applicable fields HPOUT1L_RMV_SHORT or HPOUT1R_RMV_SHORT.

The ground-referenced Headphone output drivers are designed to suppress pops and clicks when enabled or disabled. However, it is necessary to control the drivers in accordance with a defined sequence in start-up and shutdown to achieve the pop suppression. It is also necessary to schedule the DC Servo offset correction at the appropriate point in the sequence (see "DC Servo").

Table 54 and Table 55 describe the recommended sequences for enabling and disabling these output drivers.

| SEQUENCE | HEADPHONE ENABLE |
|----------|---|
| Step 1 | Write 0x0003 to Register R258 (0102h) |
| | Write 0x0C07 to Register R86 (0056h) |
| | Write 0x007E to Register R93 (005Dh) |
| | Write 0x0000 to Register R94 (005Eh) |
| | Write 0x0000 to Register R258 (0102h) |
| | (These register writes must be executed in the order noted above.) |
| Step 2 | HPOUT1L_ENA = 1 |
| | HPOUT1R_ENA = 1 |
| Step 3 | 20μs delay |
| Step 4 | HPOUT1L_DLY = 1 |
| | HPOUT1R_DLY = 1 |
| Step 5 | Run the DC Servo in Start-Up mode: |
| | Write 0x0033 to R84 (0054h) |
| Step 6 | Wait until offset correction is complete: |
| | This is indicated when DCS_STARTUP_COMPLETE=11b |
| Step 7 | Read back DCS_DAC_WR_VAL_0 and DCS_DAC_WR_VAL_1 from Register R89 (0059h) |
| Step 8 | Subtract 0x09 from DCS_DAC_WR_VAL_0 |
| | Subtract 0x05 from DCS_DAC_WR_VAL_1 |
| Step 9 | Write the updated values of DCS_DAC_WR_VAL_0 and DCS_DAC_WR_VAL_1 to Register R89 (0059h) |
| Step 10 | Run the DC Servo in DAC Write mode: |
| | Write 0x000F to R84 (0054h) |
| Step 11 | HPOUT1L_OUTP = 1 |
| | HPOUT1L_RMV_SHORT = 1 |
| | HPOUT1R_OUTP = 1 |
| | HPOUT1R_RMV_SHORT = 1 |

 Table 56 Headphone Output Signal Paths Control

OUTPUT MIXER CONTROL

The Output Mixer path select and volume controls are described in Table 57 for the Left Channel (MIXOUTL) and Table 58 for the Right Channel (MIXOUTR). The gain of each of input path may be controlled independently in the range 0dB to -9dB.

Note that the DAC input levels may also be controlled by the DAC Output Paths digital volume controls(see "Digital Mixing") and also (when applicable) by the Audio Interface Input Paths digital volume controls(see "Digital Volume and Filter Control").

When using the IN2LP, IN2LN, IN2RP or IN2RN signal paths to the output mixers, the buffered VMID reference must be enabled, using the VMID_BUF_ENA register, as described in "Reference Voltages and Master Bias".

Table 58 Right Output Mixer (MIXOUTR) Control

SPEAKER MIXER CONTROL

The Speaker Mixer path select and volume controls are described in Table 59 for the Left Channel (SPKMIXL) and Table 60 for the Right Channel (SPKMIXR).

Care should be taken when enabling more than one path to a speaker mixer in order to avoid clipping. The gain of each input path is adjustable using a selectable -6dB control in each path to facilitate this. Each Speaker Mixer output can also be muted using the SPKMIXL_VOL or SPKMIXR_VOL register.

Note that the DAC input levels may also be controlled by the DAC Output Paths digital volume controls (see "Digital Mixing") and also (when applicable) by the Audio Interface Input Paths digital volume controls (see "Digital Volume and Filter Control").

When using the IN1LP or IN1RP signal paths to the speaker mixers, the buffered VMID reference must be enabled, using the VMID_BUF_ENA register, as described in "Reference Voltages and Master Bias".

Table 60 Right Speaker Mixer (SPKMIXR) Control

OUTPUT SIGNAL PATH VOLUME CONTROL

There are six output PGAs - MIXOUTLVOL, MIXOUTRVOL, HPOUT1LVOL, HPOUT1RVOL, SPKLVOL and SPKRVOL. Each can be independently controlled, with MIXOUTLVOL and MIXOUTRVOL providing volume control to both the earpiece and line drivers, HPOUT1LVOL and HPOUT1RVOL to the headphone driver, and SPKLVOL and SPKRVOL to the speaker drivers.

The volume control of each of these output PGAs can be adjusted over a wide range of values. To minimise pop noise, it is recommended that only the MIXOUTLVOL, MIXOUTRVOL, HPOUT1LVOL, HPOUT1LVOL, SPKLVOL and SPKRVOL are modified while the output signal path is active. Other gain controls are provided in the signal paths to provide scaling of signals from different sources, and to prevent clipping when multiple signals are mixed. However, to prevent pop noise, it is recommended that those other gain controls should not be modified while the signal path is active.

To prevent "zipper noise", a zero-cross function is provided on theoutput PGAs. When this feature is enabled, volume updates will not take place until a zero-crossing is detected. In the case of a long period without zero-crossings, a timeout function is provided. When the zero-cross function is enabled, the volume will update after the timeout period if no earlier zero-cross has occurred. The timeout clock is enabled using TOCLK_ENA; the timeout period is set by TOCLK_DIV. See "Clocking and Sample Rates" for more information on these fields.

The mixer output PGA controls are shown in Table 61.The MIXOUT_VU bits control the loading of the output mixer PGA volume data. When MIXOUT_VU is set to 0, the volume control data will be loaded into the respective control register, but will not actually change the gain setting. The output mixer PGA volume settings are both updated when a 1 is written toeither MIXOUT_VU bit. This makes it possible to update the gain of both output paths simultaneously.

Table 61 Mixer Output PGA (MIXOUTLVOL, MIXOUTRVOL) Control

The headphone output PGA controls are shown inTable 62.The HPOUT1_VU bits control the loading of the headphone PGA volume data. When HPOUT1_VU is set to 0, the volume control data will be loaded into the respective control register, but will not actually change the gain setting. The headphone PGA volume settings are both updated when a 1 is written toeither HPOUT1_VU bit. This makes it possible to update the gain of both output paths simultaneously.

The HPOUT1_ATTN register controls a -3dB attenuation function in the HPOUT1L and HPOUT1R signal paths. (Note that this single register applies to the Left and Right output paths.) The output path Signal to Noise Ratio (SNR) may be improved when the HPOUT1_ATTN bit is set, but the maximum signal level is reduced by 3dB.

Note that, when the HPOUT1_ATTN register is updated in Register Control mode (CP_DYN_PWR=0), the HPOUT1_ATTN function is not fully implemented until a '1' has been written to HPOUT1_VU. See "Charge Pump" for details of the CP_DYN_PWR register bit.

The DAC1L_TO_HPOUT1L and DAC1R_TO_HPOUT1R register bits allow the DACL and DACR outputs to be selected as the single input to the HPOUT1L and HPOUT1R headphone output PGAs respectively. When these bits are asserted, the respective output mixer settings are ignored, and only the DAC path(s) are enabled. Note that these register controls are provided for software compatibility with WM8994; it is not recommended to use these register bits.

SPEAKER BOOST MIXER

Each speaker driver has its own boost mixer which performs a dual role. It allows the output from the left speaker mixer (via SPKLVOL) or the right speaker mixer (via SPKRVOL) to be routed to either speaker driver. The speaker boost mixers are controlled using the registers defined in Table 65 below.

The second function of the speaker boost mixers is that they provide an additional AC gain (boost) function to shift signal levels between the AVDD1 and SPKVDD voltage domains for maximum output power. The AC gain (boost) function is described in the "Analogue Outputs" section.

Table 65 Speaker Boost Mixer (SPKOUTLBOOST, SPKOUTRBOOST) Control

EARPIECE DRIVER MIXER

The earpiece driver has a dedicated mixer, HPOUT2MIX, which is controlled using the registers defined in Table 66. The earpiece driver is configurable to select output from the left output mixer (via MIXOUTLVOL) or the right output mixer (via MIXOUTRVOL).

Care should be taken to avoid clipping when enabling more than one path to the earpiece driver. The HPOUT2VOL volume control can be used to avoid clipping when more than one full scale signal is input to the mixer.

LINE OUTPUT MIXERS

The WM1811A provides two pairsof line outputs, both with highly configurable output mixers. The outputs LINEOUT1N and LINEOUT1P can be configured as two single-ended outputs or as a differential output. In the same manner, LINEOUT2N and LINEOUT2P can be configured either as two single-ended outputs or as a differential output. The respective line output mixers can be configured in single-ended mode or differential mode; each mode supports multiple signal path configurations.

LINEOUT1 single-ended mode is selected by setting LINEOUT1_MODE = 1. In single-ended mode, any of three possible signal paths may be enabled:

- MIXOUTL (left output mixer) to LINEOUT1P
- MIXOUTR (right output mixer) to LINEOUT1N
- MIXOUTL (left output mixer) to LINEOUT1N

LINEOUT1 differential mode is selected by setting LINEOUT1_MODE = 0. In differential mode, any of three possible signal paths may be enabled:

- MIXOUTL (left output mixer) to LINEOUT1N and LINEOUT1P
- IN1L (input PGA) to LINEOUT1Nand LINEOUT1P
- IN1R (input PGA) to LINEOUT1Nand LINEOUT1P

The LINEOUT1output mixers are controlled as described in Table 67. Care should be taken to avoid clipping when enabling more than one path to the line outputmixers. The LINEOUT1_VOL control can be used to provide -6dB attenuation when more than one full scale signal is applied.

When using the LINEOUT1 mixers in single-ended mode, a buffered VMID must be enabled. This is achieved by setting LINEOUT_VMID_BUF_ENA, as described in the "Analogue Outputs" section.

Table 68 LINEOUT2N and LINEOUT2P Control

The WM1811A incorporates a dual-mode Charge Pump which generates the supply rails for the headphone output drivers, HPOUT1L and HPOUT1R.

The Charge Pump has a single supply input, CPVDD, and generates split rails CPVOUTP and CPVOUTN according to the selected mode of operation.

The Charge Pump connections are illustrated in Figure 28 (see "Applications Information" for external component values). An input decoupling capacitor may also be required at CPVDD, depending upon the system configuration.

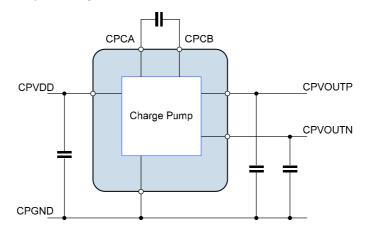

Figure 28 Charge Pump External Connections

The Charge Pump is enabled by setting the CP_ENA bit. When enabled, the charge pump adjusts the output voltages (CPVOUTP and CPVOUTN) as well as the switching frequency in order to optimise the power consumption according to the operating conditions. This can take two forms, which are selected using the CP_DYN_PWR register bit.

- Register control (CP_DYN_PWR = 0)
- Dynamic control (CP_DYN_PWR = 1)

Under Register control, the HPOUT1L_VOL and HPOUT1R_VOL register settings are used to control the charge pump mode of operation.

Under Dynamic control, the audio signal level in the digital audio interface is used to control the charge pump mode of operation. The CP_DYN_SRC_SEL register determines which of the digital signal paths is used for this function - this may be the AIF1 DAC path or the AIF2 DAC path. The CP_DYN_SRC_SEL should be set according to the active source for the HPOUT1L and HPOUT1R outputs.

The Dynamic Charge Pump Control mode is the Wolfson 'Class W' mode, which allows the power consumption to be optimised in real time, but can only be used if a single AIF source is the only signal source. The Class W mode should not be used if any of the bypass paths are used to feed analogue inputs into the output signal path, or if more than one AIF source is used to feed the headphone output via the Digital Mixers.

The Charge Pump operating mode defaults to Register control; Dynamic control may be selected by setting the CP_DYN_PWR register bit, if appropriate.

Note that the charge pump clock is derived from internal clock SYSCLK; either MCLK or the FLL output selectable using the SYSCLK_SRC bit. Under normal circumstances an external clock signal must be present for the charge pump to function. However, the FLL has a free-running mode that does not require an external clock but will generate an internal clock suitable for running the charge pump. The clock division from SYSCLK is handled transparently by the WM1811A without user intervention, as long as SYSCLK and sample rates are set correctly. Refer to the "Clocking and Sample Rates" section for more detail on the FLL and clocking configuration.

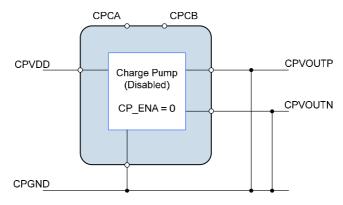

PD, August 2014, Rev 4.2

When the Charge Pump is disabled, the output can be left floating or can be actively discharged, depending on the CP_DISCH control bit.

If the headphone output drivers (HPOUT1L and HPOUT1R) are not used, then the Charge Pump and the associated external components are not required. The Charge Pump and Headphone drivers should not be enabled in this case (CP_ENA=0, HPOUT1L_ENA=0, HPOUT1R_ENA=0).

If the Charge Pump is not used, and the associated external components are omitted, then the CPCA and CPCB pins can be left floating; the CPVOUTP and CPVOUTN pins should be grounded as illustrated in Figure 29.

Note that, when the Charge Pump is disabled, it is still recommended that the CPVDD pin is kept within its recommended operating conditions.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

The Charge Pump control fields are described in Table 69.

Table 69 Charge Pump Control

The WM1811A provides a DC servo circuit on the headphone outputs HPOUT1L and HPOUT1R in order to remove DC offset from these ground-referenced outputs. When enabled, the DC servo ensures that the DC level of these outputs remains within 1mV of ground. Removal of the DC offset is important because any deviation from GND at the output pin will cause current to flow through the load under quiescent conditions, resulting in increased power consumption. Additionally, the presence of DC offsets can result in audible pops and clicks at power up and power down.

DC SERVO ENABLE AND START-UP

The DC Servo circuit is enabled on HPOUT1L and HPOUT1R by setting DCS_ENA_CHAN_0and DCS_ENA_CHAN_1respectively. When the DC Servo is enabled, the DC offset correction can be commanded in two different ways, as described below.

The DCS_TIMER_PERIOD_01 register must be set to 0000 for correct operation of the DC Servo. This register must be set to 0000 before enabling the DC Servo.

Writing a logic 1 to DCS_TRIG_STARTUP_*n* initiates a series of DC offset measurements and applies the necessary correction to the associated output; ('n' = 0for Left channel, 1for Right channel). On completion, the headphone output will be within 1mV of AGND. This mode is recommended for typical applications. Completion of the DC offset correction triggered in this way is indicated by the DCS_STARTUP_COMPLETE field, as described in Table 70. Typically, this operation takes 86ms per channel.

For correct operation of the DC Servo Start-Up mode, it is important that there is no active audio signal present on the signal path while the mode is running. The DC Servo Start-Up mode should be scheduled at the correct position within the Headphone Output Enable sequence, as described in the Analogue Output Signal Path" section. All other stages of the analogue signal path should be fully enabled prior to commanding the Start-Up mode; the DAC Digital Mute function should be used, where appropriate, to ensure there is no active audio signal present during the DC Servo measurements.

Writing a logic 1 to DCS_TRIG_DAC_WR_*n* causes the DC offset correction to be set to the value contained in the DCS_DAC_WR_VAL_*n* fields in Register R89. This mode is useful if the required offset correction has already been determined and stored; it is faster than the DCS_TRIG_STARTUP_*n* mode, but relies on the accuracy of the stored settings. Completion of the DC offset correction triggered in this way is indicated by the DCS_DAC_WR_COMPLETE field, as described in Table 70. Typically, this operation takes 2ms per channel.

For pop-free operation of the DC Servo DAC Write mode, it is important that the mode is scheduled at the correct position within the Headphone Output Enable sequence, as described in the "Analogue Output Signal Path" section.

The current DC offset value for each Headphone output channel can be read from the DCS_DAC_WR_VAL_nfields. These values may form the basis of settings that are subsequently used by the DC Servo in DAC Write mode. Note that these fields have a different definition for Read and Write, as described in Table 70.

When using either of the DC Servo options above, the status of the DC offset correction process is indicated by the DCS_CAL_COMPLETE field; this is the logical OR of the DCS_STARTUP_COMPLETE and DCS_DAC_WR_COMPLETE fields.

The DCS_DAC_WR_COMPLETE bits can be used as inputs to the Interrupt control circuit or used to generate an external logic signal on a GPIO pin. See "Interrupts" and "General Purpose Input/Output" for further details.

The DC Servo control fields associated with start-up operation are described in Table 70. It is important to note that, to minimise audible pops/clicks, the Start-Up and DAC Write modes of DC Servo operation should be commanded as part of a control sequence which includes muting and shorting of the headphone outputs.

Table 70 DC Servo Control

GPIO / INTERRUPT OUTPUTS FROM DC SERVO

When using the DC Servo Start-Up or DAC Write modes, the DCS_CAL_COMPLETE register provides readback of the status of the DC offset correction. This can be read from register R88 as described in Table 70.

The DCS_CAL_COMPLETE bits can also be used as inputs to the Interrupt control circuit and used to trigger an Interrupt event - see "Interrupts".

The DCS_CAL_COMPLETE bits can also be used as inputs to the GPIO function and used to generate external logic signals indicating the DC Servo status. See "General Purpose Input/Output" for details of how to configure a GPIO pin to output the DC Servo status.

ANALOGUE OUTPUTS

The speaker, headphone, earpiece and line outputs are highly configurable and may be used in many different ways.

SPEAKER OUTPUT CONFIGURATIONS

The speaker outputs SPKOUTL and SPKOUTR can be driven by either of the speaker mixers, SPKMIXL or SPKMIXR. Fine volume control is available on the speaker mixer paths using the SPKLVOL and SPKRVOL PGAs. A boost function is available on the speaker output paths. For information on the speaker mixing options, refer to the "Analogue Output Signal Path" section.

The speaker outputs SPKOUTL and SPKOUTR operate in a BTL configuration.

The speaker outputs can be configured as a pair of stereo outputs, or as a single mono output. Note that, for applications requiring only a single speaker output, it is possible to improve the THD performance by configuring the speaker outputs in mono mode.See "Typical Performance" for further details.

The mono configuration is selected by applying a logic high input to the SPKMODE pin (D5), as described in Table 71. For Stereo mode this pin should be connected to GND. Note that SPKMODE is referenced to DBVDD1.

An internal pull-up resistor is enabled by default on the SPKMODE pin; this can be configured using the SPKMODE_PU register bit described in Table 72.

| SPEAKER CONFIGURATION | SPKMODE PIN (D5) |
|-----------------------|------------------|
| Stereo Mode | GND |
| Mono Mode | DBVDD1 |

Table 71 SPKMODE Pin Function

In the mono configuration, the P channels, SPKOUTLP and SPKOUTRP should be connected together on the PCB, and similarly with the N channels, SPKOUTLN and SPKOUTRN, as illustrated in Figure 30. In this configuration bothleft and right speaker drivers should be enabled (SPKOUTL_ENA=1 and SPKOUTR_ENA=1), but path selection and volume controls are available on left channel only (SPKMIXL, SPKLVOL and SPKOUTLBOOST).

Note that the minimum speaker load resistance and the maximum power output has a dependency on the SPKMODE output configuration, and also on the Class D/AB mode selection. See "Electrical Characteristics" for further details.

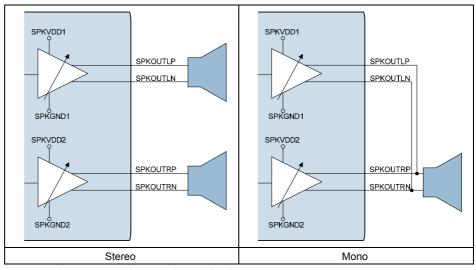

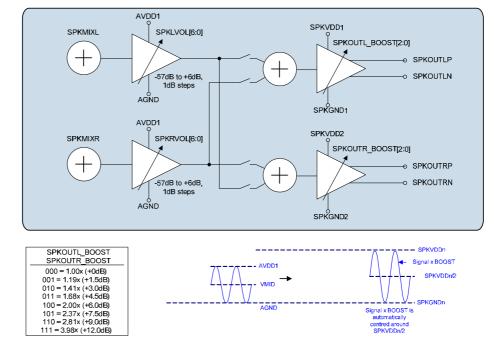

Figure 30 Stereo / Mono Speaker Output Configurations

Eight levels of AC signal boost are provided in order to deliver maximum output power for many commonly-used SPKVDD/AVDD1 combinations. (Note that SPKVDD1 powers the Left Speaker driver, and SPKVDD2 powers the Right Speaker driver; it is assumed that SPKVDD1 = SPKVDD2 = SPKVDD2.)

The signal boost options are available. The AC boost levels from 0dB to +12dB are selected using register bits SPKOUTL_BOOST and SPKOUTR_BOOST. To prevent pop noise, SPKOUTL_BOOST and SPKOUTR_BOOST should not be modified while the speaker outputs are enabled. Figure 31 illustrates the speaker outputs and the mixing and gain/boost options available.

Ultra-low leakage and high PSRR allow the speaker supply SPKVDD to be directly connected to a lithium battery. Note that an appropriate SPKVDD supply voltage must be provided to prevent waveform clipping when speaker boost is used.

DC gain is applied automatically, with a shift from VMID to SPKVDD/2. This provides optimum signal swing for maximum output power.

The AC and DC gain functions are illustrated in Figure 31.

Figure 31 Speaker Output Configuration and AC Boost Operation

Table 72 Speaker Mode and Boost Control

Clocking of the Class D output driver is derived from SYSCLK. The clocking frequency division is configured automatically, according to the AIFn_SR and AIFnCLK_RATE registers. (See "Clocking and Sample Rates" for further details of the system clocks and control registers.)

The Class D switching clock is enabled whenever SPKOUTL_ENA or SPKOUTR_ENA is set. The frequency is as described in Table 73.

When AIF1CLK is selected as the SYSCLK source (SYSCLK_SRC = 0), then the Class D clock frequency is controlled by the AIF1_SR and AIF1CLK_RATE registers.

When AIF2CLK is selected as the SYSCLK source (SYSCLK_SRC = 1), then the Class D clock frequency is controlled by the AIF2_SR and AIF2CLK_RATE registers.

The applicable clocks (SYSCLK, AIF1CLK or AIF2CLK) must be present and enabled when using the speaker outputs in Class D mode. The presence of a suitable clock is automatically detected by the WM1811A; if the clock signal is absent, then the speaker outputs will be disabled.

Production Data

| SAMPLE | SYSCLK RATE (AIFnCLK / fs ratio) | | | | | | | |
|------------|----------------------------------|-------|-------|-------|-------|-------|-------|------|

Table 73 Class D Switching Frequency (kHz)

HEADPHONE OUTPUT CONFIGURATIONS

The headphone outputs HPOUT1L andHPOUT1R are driven by the headphone output PGAs HPOUT1LVOL and HPOUT1RVOL. Each PGA has its own dedicated volume control, as described in the "Analogue Output Signal Path" section. The input to these PGAs can be either the output mixers MIXOUTL and MIXOUTR or the direct DAC outputs DACL and DACR.

The headphone output driver is capable of driving up to 30mW into a 16 Ω load or 25mW into a 32 Ω load such as a stereo headset or headphones. The outputs are ground-referenced, eliminating any requirement for AC coupling capacitors. This is achieved by having separate positive and negative supply rails powered by an on-chip charge pump.A DC Servo circuit removes any DC offset from the headphone outputs, suppressing 'pop' noiseand minimising power consumption. The Charge Pump and DC Servo are described separately (see "Charge Pump" and "DC Servo" respectively).

The typical headphone output connection is illustrated in Figure 32.

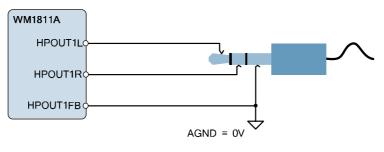

Figure 32 Headphone Output Configuration

The headphone output incorporates a common mode, or ground loop, feedback path which provides rejection of system-related ground noise. The return path is via HPOUT1FB. This pin must be connected to ground for normal operation of the headphone output. No register configuration is required.

Note that the HPOUT1FB pin should be connected to GND close to the headphone jack, as illustrated in Figure 32.

EARPIECE DRIVER OUTPUT CONFIGURATIONS

The earpiece driver outputs HPOUT2P and HPOUT2N are driven by the HPOUT2MIX output mixer, which takes its inputs from the mixer output PGAs MIXOUTLVOL and MIXOUTRVOL. Fine volume control is available using MIXOUTLVOL and MIXOUTRVOL. A selectable -6dB attenuation is available on the HPOUT2MIX output, as described in Table 66 (refer to the "Analogue Output Signal Path" section).

The earpiece outputs are designed to operate in a BTL configuration, driving 50mW into a typical 16 $\!\Omega$ ear speaker.

For suppression of pop noise there are two separate enables for the earpiece driver; HPOUT2_ENA enables the output stage and HPOUT2_IN_ENA enables the mixer and input stage. HPOUT2_IN_ENA should be enabled a minimum of 50µs before HPOUT2_ENA.

LINE OUTPUT CONFIGURATIONS

The four line outputs LINEOUT1P, LINEOUT1N, LINEOUT2P and LINEOUT2N provide a highly flexible combination of differential and single-ended configurations, each driven by a dedicated output mixer. There is a selectable -6dB gain option in each mixer to avoid clipping when mixing more than one signal into a line output. Additional volume control is available at other locations within each of the supported signal paths. For more information about the line output mixing options, refer to the "Analogue Output Signal Path" section.

Typical applications for the line outputs (single-ended or differential) are:

- Handset or headset microphone output to external voice CODEC
- Stereo line output
- Output to external speaker driver(s) to support additional loudspeakers

When single-ended mode is selected for either LINEOUT1 or LINEOUT2, a buffered VMID must be enabled as a reference for the outputs. This is enabled by setting the LINEOUT_VMID_BUF_ENA bit as defined in Table 74.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|----------------------------|-----|--------------------------|---------|--|
| R56 (0038h) AntiPOP (1) | 7 | LINEOUT_VMID_BUF_ ENA | 0 | Enables VMID reference for line outputs in single-ended mode 0 = Disabled 1 = Enabled |

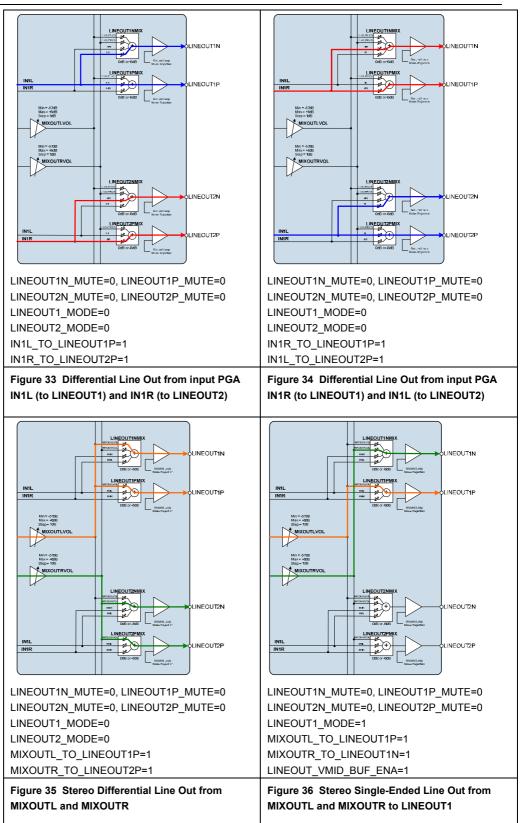

Table 74 LINEOUT VMID Buffer for Single-Ended Operation

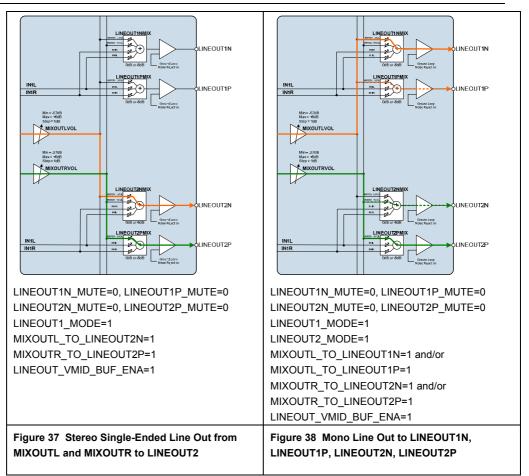

Some example line output configurations are listed and illustrated below.

- Differential line output from Mic/Line input on IN1L PGA
- Differential line output fromMic/Line input on IN1R PGA
- Stereo differential line output from output mixers MIXOUTL and MIXOUTR
- Stereo single-ended line output from output mixer to either LINEOUT1 or LINEOUT2
- Mono single-ended line output from output mixer

Production Data

The line outputs incorporate a common mode, or ground loop, feedback path which provides rejection of system-related ground noise. The return path, via LINEOUTFB, is enabled separately for LINEOUT1 and LINEOUT2 using the LINEOUT1_FB and LINEOUT2_FB bits as defined in Table 75.

Ground loop feedback is a benefit to single-ended line outputs only; it is not applicable to differential outputs, which already inherently offer common mode noise rejection.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|--------------------------------------|-----|-------------|---------|---|
| R55 (0037h) Additional Control | 7 | LINEOUT1_FB | 0 | Enable ground loop noise feedback on LINEOUT1 0 = Disabled 1 = Enabled |
| | 6 | LINEOUT2_FB | 0 | Enable ground loop noise feedback on LINEOUT2 0 = Disabled 1 = Enabled |

Table 75 Line Output Ground Loop Feedback Enable

EXTERNAL ACCESSORY DETECTION

The WM1811A provides external accessory detection functions which can sense the presence and impedance of external components. This can be used to detect the insertion or removal of an external headphone or headset, and to provide an indication of key/button push events.

Jack insertion is detected using the JACKDET pin, which must be connected to switch contacts within the jack socket. An Interrupt event is generated whenever a jack insertion or jack removal event is detected.

Microphones, push-buttons and other accessories can be detected via the MICDET pin. The presence of a microphone, and the status of a hookswitch can be detected. This feature can also be used to detect push-button operation.

Note that clocking is required for all of the external accessory detection functions. The WM1811A can support accessory detection using a low frequency (eg. 32kHz) clock for reduced power consumption.

JACK DETECT

The WM1811A provides support for jack insertion switch detection. The Jack Detect function also enables the device to be configured for low power standby modes; typical use cases are where an application is idle in standby mode until a headphone or headset jack is inserted.

Jack insertion and removal is detected using the JACKDET pin. The recommended external connection circuit is illustrated in Figure 39. The status of the jack insertion switch can be read using the JACKDET_LVL register.

The JACKDET input de-bounce is enabled or disabled using the JACKDET_DB register, as described in Table 77.

The Jack Detect function is enabled whenever JACKDET_MODE > 00. An Interrupt Request (IRQ) event is generated whenever a jack insertion or jack removal is detected (see "Interrupts").

Different settings of JACKDET_MODE allow different low power configurations to be selected. Note that audio and/or microphone detection functions are not supported under these low power conditions. The options provided by the JACKDET_MODE register are summarised in Table 76.

When JACKDET_MODE = 01, the LDO1 regulator output must be configured to be floating when disabled. The LDO1_DISCH bit (see Table 127) must be set to 0 before setting JACKDET_MODE = 01.

Note that, in modes where MICDET (microphone / accessory detect) functionality is required, this must be configured as described in the following section. In modes where the Audio functions are not supported, none of the WM1811A analogue/digital audio record or playback functions are possible.

| JACKDET_MODE | JACK DETECT | MICROPHONE / ACCESSORY DETECT | AUDIO FUNCTIONS | TYPICAL USE CASE | |
|---|----------------------|-------------------------------------|----------------------|--|--|
| 00 | | ✓ | ✓ | Full device operation (eg. audio record/playback). (Note that Jack Detect is not supported.) | |
| 01 | ✓ | ✓ | | Device in idle mode, monitoring accessory activity (eg. button press, jack removal etc.) | |
| 10 | ✓ | | | Device in standby mode, awaiting jack insertion - Lowest power external accessory detection mode. | |
| 11 | ✓ | ✓ | ✓ | Full device operation (eg. audio record/playback). | |
| Note that JACKDET_MODE = 01 or 10 are not supported if AVDD1 or DCVDD is supplied externally. | | | | | |
| These settings must r | not be selected if A | VDD1 or DCVDD is | s supplied externall | y (ie. if LDO1 or LDO2 is not used). | |

Table 76 Jack Detect Modes

When JACKDET_MODE = 01, LDO1 and LDO2 are disabled. AVDD1 is powered from AVDD2, and DCVDD is powered from DBVDD1.

When JACKDET_MODE = 10, LDO1 and LDO2 are disabled. AVDD1 is unpowered, and DCVDD is powered from DBVDD1.

Note that, in both modes described above, the LDO1ENA input pin is ignored. The LDO2ENA pin must be asserted (logic '1') to power DCVDD, although LDO2 will operate in a 'bypass' mode, connecting DCVDD to DBVDD1.

Note that, in both modes described above, the AVDD1 voltage is below the minimum recommended operating level. Analogue or digital audio functions cannot be supported in these modes.

Note that the LDO configuration for JACKDET_MODE = 01 or 10 assumes that AVDD1 and DCVDD are powered from LDO1 and LDO2 respectively. If AVDD1 or DCVDD is powered externally (not from the internal LDOs), then these settings of JACKDET_MODE must not be used.

If AVDD1 or DCVDD is powered externally (not from the internal LDOs), then the Jack Detect function, when required, should be enabled by setting JACKDET_MODE = 11.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

| | | | | |
| | | | | MICDET (microphone/accessory |
| | | | | detection) is not supported when JACKDET_MODE = 10. |
| | | | | Analogue/Digital audio functions |
| | | | | are not supported when |
| | | | | JACKDET_MODE = 01 or 10. |
| | | | | LDO1_DISCH must be set to 0 when JACKDET_MODE=01. |
| | | | | Settings 01 and 10 must not be selected if AVDD1 or DCVDD is supplied externally (ie. if LDO1 or LDO2 is not used). |

The control registers associated with the Jack Detect function are described in Table 77.

Table 77 Jack Detect Control

Clocking for the jack detection function is derived from SYSCLK (defined in the "Clocking and Sample Rates" section). The WM1811A can support accessory detection using a low frequency (eg. 32kHz) clock for reduced power consumption. See the "External Accessory Detection Clocking" section below for further details.

To configure the WM1811A in its lowest power condition, also supporting the Jack Detect function, the following actions are recommended:

- Select lowest power Jack Detection mode (JACKDET_MODE = 10)
- Select 32kHz SYSCLK
- Disable the Thermal sensor (TSHUT_ENA = 0)
- Configure LDO1 output to float when disabled (LDO1_DISCH = 0)
- Minimise any static current leakage paths on digital inputs where internal pull-up or pulldown resistors are enabled (ie. disable the pull-up/pull-down resistors on these inputs)

Care should be taken to restore all applicable device settings when normal operation is resumed following the low power jack detection. In particular, note that the thermal sensor should be enabled for normal operation.

A recommended connection circuit, including headphone output on HPOUT1 and microphone connections, is shown in Figure 39. See "Applications Information" for details of recommended external components.

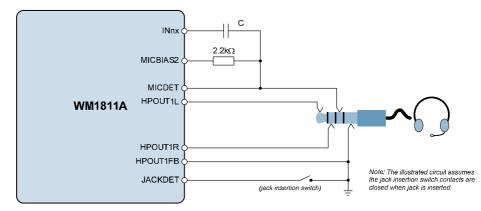

Figure 39 Jack Detect and External Accessory Connections

The internal comparator circuit used to detect the JACKDET status is illustrated in Figure 40.

The threshold voltages for the jack detect circuit are noted in the "Electrical Characteristics". Note that separate thresholds are defined for jack insertion and jack removal.

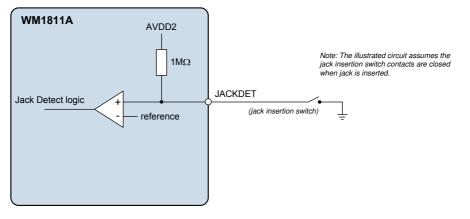

Figure 40 Jack Detect Comparator

MICROPHONE / ACCESSORY DETECT

The WM1811A accessory detection circuit measures the impedance of an external load connected to the MICDET pin. This feature can be used to detect the insertion or removal of a microphone, and the status of the associated hookswitch. It can also be used to detect push-button status or the connection of other external accessories.

The microphone detection circuit measures the impedance connected to MICDET, and reports whether the measured impedance lies within one of 9 pre-defined levels (including the 'no accessory detected' level). This means it can detect the presence of a typical microphone and up to 7 push-buttons. One of the impedance levels is specifically designed to detect a video accessory (typical 75 Ω) load if required.

The microphone detection circuit uses the MICBIAS2 output as a reference. The WM1811A will automatically enable MICBIAS2 when required in order to perform the detection function; this allows the detection function to be supported in low-power standby operating conditions.

Microphone detection is enabled by setting the MICD_ENA register. When microphone detection is enabled, the WM1811A performs a number of measurements in order to determine the MICDET impedance. The measurement process is repeated at a cyclic rate controlled by MICD_RATE.(The MICD_RATE register selects the delay between completion of one measurement and the start of the next.)

For best accuracy, the measured impedance is only deemed valid after more than one successive measurement has produced the same result. The MICD_DBTIME register provides control of the debounce period; this can be either 2 measurements or 4 measurements.

When the microphone detection result has settled (ie. after the applicable de-bounce period), the WM1811A indicates valid data by setting the MICD_VALID bit. The measured impedance is indicated using the MICD_LVL and MICD_STS register bits, as described in Table 78.

The MICD_VALID bit, when set, remains asserted for as long as the microphone detection function is enabled (ie. while MICD_ENA = 1). If the detected impedance changes, then the MICD_LVL and MICD_STS fields will change, but the MICD_VALID bit will remain set, indicating valid data at all times.

Note that the impedance levels quoted in the MICD_LVL description assume that a microphone (475 Ω to 30k Ω impedance) is also present on the MICDET pin. The limits quoted in the "Electrical Characteristics" refer to the combined effective impedance on the MICDET pin. Typical external components are described in the "Applications Information" section.

The microphone detection reports a measurement result in one of the pre-defined impedance levels. Each measurement level can be enabled or disabled independently; this provides flexibility according to the required thresholds, and offers a faster measurement time in some applications. The MICD_LVL_SEL register is described in detail later in this section.

Clocking for the microphone detection function is derived from SYSCLK (defined in the "Clocking and Sample Rates" section). The WM1811A can support accessory detection using a low frequency (eg. 32kHz) clock for reduced power consumption. See the "External Accessory Detection Clocking" section below for further details.

The microphone detection function is an input to the Interrupt control circuit and can be used to trigger an Interrupt event every time an accessory insertion, removal or impedance change is detected. See "Interrupts" for further details.

The microphone detection function can also generate a GPIO output, providing an external indication of the microphone detection. This GPIO output is pulsed every time an accessory insertion, removal or impedance change is detected. See "General Purpose Input/Output" for details of how to configure a GPIO pin to output the microphone detection signal.

The register fields associated with Microphone Detection (or other accessories) are described in Table 78. The external circuit configuration is illustrated in Figure 41.

Table 78 Microphone Detect Control

The external connections for the Microphone Detect circuit are illustrated in Figure 41. In typical applications, it can be used to detect a microphone or button press.

The microphone detection function uses MICBIAS2 as a reference. The microphone detection function will automatically enable MICBIAS2 when required for MICDET impedance measurement.

If MICBIAS2 is not already enabled (ie. if MICB2_ENA = 0), then MICBIAS2 will be enabled for short periods of time only, every time the impedance measurement is scheduled. To allow time for the MICBIAS2 source to start-up, a time delay is applied before the measurement is performed; this is configured using the MICD_BIAS_STARTTIME register, as described in Table 78.

The MICD_BIAS_STARTTIME register should be set to 16ms or more if MICB2_RATE = 1 (pop-free start-up / shut-down). The MICD_BIAS_STARTTIME register should be set to 0.25ms or more if MICB2_RATE = 0 (fast start-up / shut-down).

If the MICBIAS2 reference is not enabled continuously (ie. if MICB2_ENA = 0), then the MICBIAS2 discharge bit (MICB2_DISCH) should be set to 0.

The MICBIAS sources are configured using the registers described in Table 1, in the "Analogue Input Signal Path" section.

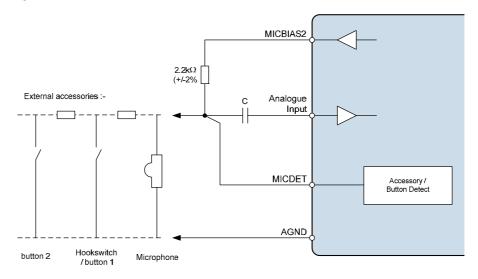

Figure 41 Microphone Detect Interface

The MICD_LVL_SEL [7:0] register bits allow each of the impedance measurement levels to be enabled or disabled independently. This allows the function to be tailored to the particular application requirements.

If one or more bits within the MICD_LVL_SEL register is set to 0, then the corresponding impedance levelwill be disabled. Any measured impedance which lies in a disabled level will be reported as the next lowest, enabled level.

For example, the MICD_LVL_SEL [3] bit enables the detection of impedances around 77 Ω . If MICD_LVL_SEL [3] = 0, then an external impedance of 77 Ω will not be indicated as 77 Ω but will be indicated as 47 Ω ; this would be reported in the MICD_LVL register as MICD_LVL [3] = 1.

With all measurement levels enabled, the WM1811A can detect the presence of a typical microphone and up to 7 push-buttons. The microphone detect function is specifically designed to detect a video accessory (typical 75 Ω) load if required.

See "Applications Information" for typical recommended external components for microphone, video or push-button accessory detection.

The microphone detection circuit assumes that a $2.2k\Omega(2\%)$ resistor is connected to MICBIAS2, as illustrated. Different resistor values will lead to inaccuracy in the impedance measurement.

PD, August 2014, Rev 4.2

The measurement accuracy of the microphone detect function is assured whenever the connected load is within the applicable limits specified in the "Electrical Characteristics". Note that a $2.2k\Omega$ (2%) resistor must also be connected between MICDET and MICBIAS2.

Note that the connection of a microphone will change the measured impedance on the MICDET pin; see "Applications Information" for recommended components for typical applications.

The measurement time varies between $100\mu s$ and $500\mu s$ according to the impedance of the external load. A high impedance will be measured faster than a low impedance.

The timing of the microphone detect function is illustrated in Figure 42. Two different cases are shown, according to whether MICBIAS2 is enabled periodically by the impedance measurement function (MICB2_ENA=0), or is enabled at all times (MICB2_ENA=1).

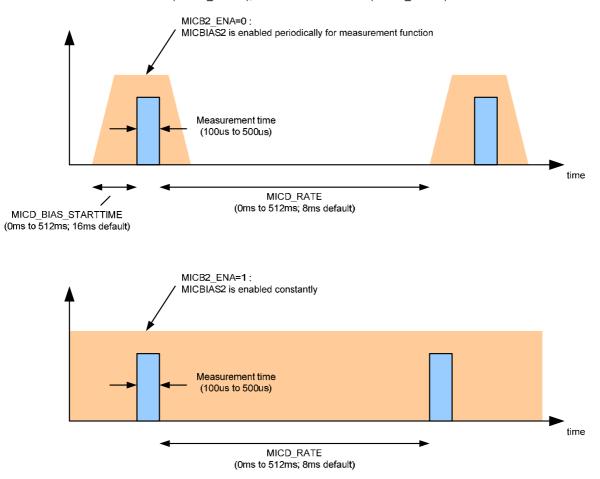

Figure 42 Microphone Detect Timing

EXTERNAL ACCESSORY DETECTION CLOCKING

Clocking for the jack detect and microphone detection functions is derived from SYSCLK (defined in the "Clocking and Sample Rates" section).

When AIF1CLK is selected as the SYSCLK source (SYSCLK_SRC = 0), then AIF1CLK must be present and enabled when using the external accessory detect functions. The AIF1_SR and AIF1CLK_RATE registers must be set to values that are consistent with the available AIF1CLK frequency.

When AIF2CLK is selected as the SYSCLK source (SYSCLK_SRC = 1), then AIF2CLK must be present and enabled when using the external accessory detect functions. The AIF2_SR and AIF2CLK_RATE registers must be set to values that are consistent with the available AIF2CLK frequency.

The accessory detection functions can also be supported using a low frequency (eg. 32kHz) clock, as described below - see "External Accessory Detection with Low Frequency SYSCLK".

The Frequency Locked Loop (FLL) free-running mode provides flexibility to clock the accessory detection functions without any external reference clock, eg. in low-power standby operating conditions. See "Clocking and Sample Rates" for details of the WM1811A clocking options and FLL.

EXTERNAL ACCESSORY DETECTION WITH LOW FREQUENCY SYSCLK

Clocking for the jack detect and microphone detection function can be derived from AIF1CLK or AIF2CLK, as described earlier.

Under normal circumstances, the AIFn_SR and AIFnCLK_RATE registers must be set to values that are consistent with the available AIFnCLK frequency. The register settings support AIFnCLK frequencies of 1.024MHz or higher.

The microphone detection function can also be supported using a low frequency (eg. 32kHz) clock. In this case, the selected SYSCLK source (AIF1CLK or AIF2CLK) should be configured with the following register settings:

- AIFnCLK_RATE = 0001 (AIFnCLK / fs = 128)
- AIFn_SR = 0000 (fs = 8kHz)

The register settings above configure the WM1811A for AIFnCLK = 1.024MHz. If the available clock is a different frequency (eg. 32kHz), then the timings set by the MICD_RATE and MICD_BIAS_STARTUP registers will be scaled accordingly. In the case of a 32kHz clock, these times will be extended by a factor of 32 (calculated as 1024000 / 32000).

For example, under normal circumstances, setting MICD_RATE = 0011 selects a 1ms delay between successive measurements. Using a 32kHz reference clock, and the register settings above, then MICD_RATE = 0011 will select a 32ms delay.

GENERAL PURPOSE INPUT/OUTPUT

The WM1811A provides a number of GPIO functions to enable interfacing and detection of external hardware and to provide logic outputs to other devices. The input functions can be polled directly or can be used to generate an Interrupt (IRQ) event. The GPIO and Interrupt circuits support the following functions:

- Alternate interface functions (AIF3)
- Button detect (GPIO input)
- Logic '1' and logic '0' output (GPIO output)
- Interrupt (IRQ) status output
- Over-Temperature detection
- Microphone accessory status detection
- Frequency Locked Loop (FLL) Lock status output
- Sample Rate Conversion (SRC) Lock status output
- Dynamic Range Control (DRC) Signal activity detection
- Digital Core FIFO error status output
- Clock output (SYSCLK divided by OPCLK_DIV)
- Frequency Locked Loop (FLL) Clock output

GPIO CONTROL

For each GPIO, the selected function is determined by the GPn_FN field, where n identifies the GPIO pin (1, 8, 9, 10, 11). The pin direction, set by GPn_DIR, must be set according to function selected by GPn_FN.

The digital audio interface AIF3 is supported using GPIO pins; the applicable pin functions are selected by setting the corresponding GPn_FN register to 00h. The ADCLRCLK1 function for AIF1 is supported on GPIO1. See Table 80 for the definition of which AIF function is available on each GPIO pin.

See "Digital Audio Interface Control" for details of AIF2 and AIF3.

When a pin is configured as a GPIO input (GPn_DIR = 1), the logic level at the pin can be read from the respective GPn_LVL bit. Note that GPn_LVL is not affected by the GPn_POL bit.

A de-bounce circuit can be enabled on any GPIO input, to avoid false event triggers. This is enabled on each pin by setting the respective GPn_DB bit.

When a pin is configured as a Logic Level output (GPn_DIR = 0, GPn_FN = 01h), its level can be set to logic 0 or logic 1 using the GPn_LVL field.

When a pin is configured as an output ($GPn_DIR = 0$), the polarity can be inverted using the GPn_POL bit. When $GPn_POL = 1$, then the selected output function is inverted. In the case of Logic Level output ($GPn_FN = 01h$), the external output will be the opposite logic level to GPn_LVL when $GPn_POL = 1$.

A GPIO output can be either CMOS driven or Open Drain. This is selected on each pin using the respective GPn_OP_CFG bit.

Internal pull-up and pull-down resistors may be enabled using the GPn_PU and GPn_PD fields; this allows greater flexibility to interface with different signals from other devices.(Note that if GPn_PU and GPn_PD are both set for any GPIO pin, then the pull-up and pull-down will be disabled.)

Each of the GPIO pins is an input to the Interrupt control circuit and can be used to trigger an Interrupt event. An interrupt event is triggered on the rising and falling edge of the GPIO input. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

PD, August 2014, Rev 4.2

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

| | 6 | GPn_LVL | 0 | GPIOn level. Write to this bit to set a GPIO output. Read from this bit to read GPIO input level. |
| | | | | For output functions only, when GPn_POL is set, the register contains the opposite logic level to the external pin. |
| | 4:0 | GPn_FN [4:0] | | GPIOn Pin Function |
| | | | | (see Table 80 for details) |
| | | | | GP1_FN default = 0000 |
| | | | | GP8_FN default = 0001 |
| | | | | GP9_FN default = 0001 |
| | | | | GP10_FN default = 0001 |
| | | | | GP11_FN default = 0001 |

The register fields that control the GPIO pins are described inTable 79.

Note: *n* is a number (1, 8, 9, 10, 11) that identifies the individual GPIO. Table 79 GPIO1, GPIO8, GPIO9, GPIO10 to GPIO11 Control

GPIO FUNCTION SELECT

The available GPIO functions are described in Table 80. The function of each GPIO is set using the GPn_FN register, where n identifies the GPIO pin (1, 8, 9, 10, 11). Note that the respective GPn_DIR must also be set according to whether the function is an input or output.

Table 80 GPIO Function Select

BUTTON DETECT (GPIO INPUT)

Button detect functionality can be selected on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". The same functionality can be used to support a Jack Detect input function.

It is recommended to enable the GPIO input de-bounce feature when using GPIOs as button input or Jack Detect input.

The GPn_LVL fields may be read to determine the logic levels on a GPIO input, after the selectable de-bounce controls.Note that GPn_LVL is not affected by the GPn_POL bit.

The de-bounced GPIO signals are also inputs to the Interrupt control circuit. An interrupt event is triggered on the rising and falling edge of the GPIO input. The associated interrupt bits are latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

LOGIC '1' AND LOGIC '0' OUTPUT (GPIO OUTPUT)

The WM1811A can be programmed to drive a logic high or logic low level on any GPIO pin by selecting the "GPIO Output" function as described in "GPIO Control". The output logic level is selected using the respective GPn_LVL bit.

Note that the polarity of the GPIO output can be inverted using the GPn_POL registers. If $GPn_POL = 1$, then the external output will be the opposite logic level to GPn_LVL .

INTERRUPT (IRQ) STATUS OUTPUT

The WM1811A has an Interrupt Controller which can be used to indicate when any selected Interrupt events occur. An interrupt can be generated by any of the events described throughout the GPIO function definition above. Individual interrupts may be masked in order to configure the Interrupt as required. See "Interrupts" for further details.

The Interrupt (IRQ) status may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

OVER-TEMPERATURE DETECTION

The WM1811A incorporates a temperature sensor which detects when the device temperature is within normal limits or if the device is approaching a hazardous temperature condition.

The Temperature status may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". Any GPIO pin can be used to indicate either a Warning Temperature event or the Shutdown Temperature event. De-bounce can be applied to the applicable signal using the register bits described in Table 81.

The Warning Temperature and Shutdown Temperature status are inputs to the Interrupt control circuit, after the selectable de-bounce. An interrupt event may be triggered on the rising and falling edges of these signals. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

Note that the temperature sensor can be configured to automatically disable the audio outputs of the WM1811A (see "Thermal Shutdown"). In some applications, it may be preferable to manage the temperature sensor event through GPIO or Interrupt functions, allowing a host processor to implement a controlled system response to an over-temperature condition.

The temperature sensor must be enabled by setting the TSHUT_ENA register bit. When the TSHUT_OPDIS is also set, then a device over-temperature condition will cause the speaker outputs (SPKOUTL and SPKOUTR) of the WM1811A to be disabled.

PD, August 2014, Rev 4.2

Table 81 Temperature Sensor Enable and GPIO/Interrupt Control

MICROPHONE ACCESSORY STATUS DETECTION

The WM1811A provides an impedance measurement circuit on the MICDET pin to detect the connection of a microphone or other external accessory.See "External Accessory Detection" for further details.

A logic signal from the microphone detect circuit may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". This logic signal is set high for a single pulse duration of 31μ s whenever an accessory insertion, removal or impedance change is detected.

The microphone detection circuit is also an input to the Interrupt control circuit. An interrupt event is triggered whenever an accessory insertion, removal or impedance change is detected. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

FREQUENCY LOCKED LOOP (FLL) LOCK STATUS OUTPUT

The WM1811A maintains a flag indicating the lock status of each of FLLs, which may be used to control other events if required. See "Clocking and Sample Rates" for more details of the FLL.

The FLL Lock signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The FLL Lock signals are inputs to the Interrupt control circuit. An interrupt event is triggered on the rising and falling edges of the FLL Lock signals. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

SAMPLE RATE CONVERTER (SRC) LOCK STATUS OUTPUT

The WM1811A maintains a flag indicating the lock status of each of Sample Rate Converters, which may be used to control other events if required. See "Sample Rate Conversion" for more details of the Sample Rate Converters.

The SRC Lock signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The SRC Lock signals are inputs to the Interrupt control circuit, after the selectable de-bounce. An interrupt event is triggered on the rising and falling edges of the SRC Lock signals. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

DYNAMIC RANGE CONTROL (DRC) SIGNAL ACTIVITY DETECTION

Signal activity detection is provided on each of the Dynamic Range Controllers (DRCs). These may be configured to indicate when a signal is present on the respective signal path. The signal activity status signals may be used to control other events if required. See "Digital Core Architecture" for more details of the DRCs and the available digital signal paths.

When a DRC is enabled, as described in "Dynamic Range Control (DRC)", then signal activity detection can be enabled by setting the respective [*DRC*]_SIG_DET register bit. The applicable threshold can be defined either as a Peak level (Crest Factor) or an RMS level, depending on the [*DRC*]_SIG_DET_MODE register bit. When Peak level is selected, the threshold is determined by [*DRC*]_SIG_DET_PK, which defines the applicable Crest Factor (Peak to RMS ratio) threshold. If RMS level is selected, then the threshold is set using [*DRC*]_SIG_DET_RMS. These register fields are set independently for each of the three Dynamic Range Controllers, as described in Table 82.

When the DRC is enabled in any of the ADC (digital record) paths, the associated High Pass Filter (HPF) must be enabled also; this ensures that DC offsets are removed prior to the DRC processing. The output path HPF control registers are described in Table 37 (for AIF1 output paths) and Table 45 (for AIF2 output paths). These are described in the "Digital Volume and Filter Control" section.

The DRC Signal Detect signals may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The DRC Signal Detect signals are inputs to the Interrupt control circuit. An interrupt event is triggered on the rising edge of the DRC Signal Detect signals. The associated interrupt bits are latched once set; they can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

Table 82 DRC Signal Activity Detect GPIO/Interrupt Control

DIGITAL CORE FIFO ERROR STATUS DETECTION

The WM1811A monitors the Digital Core for error conditions which may occur if a clock rate mismatch is detected. Under these conditions, the digital audio may become corrupted.

The most likely cause of a Digital Core FIFO Error condition is an incorrect system clocking configuration. See "Clocking and Sample Rates" for the WM1811A system clocking requirements.

The Digital Core FIFO Error function is provided in order that the systemconfiguration can be verified during product development.

The FIFO Error signal may be output directly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

The FIFO Error signal is an input to the Interrupt control circuit. An interrupt event is triggered on the rising edge of the FIFO Error signal. The associated interrupt bit is latched once set; it can be polled at any time or used to control the IRQ signal. See "Interrupts" for more details of the Interrupt event handling.

OPCLK CLOCK OUTPUT

A clock output (OPCLK) derived from SYSCLK may be output on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control". This clock is enabled by register bit OPCLK_ENA, and its frequency is controlled by OPCLK_DIV.

| ŝ | See "Clocking an | d Sample | e Rates" for mo | re details of t | the System Clock (SYSCLK). |

Table 83 OPCLK Control

FLL CLOCK OUTPUT

The FLL Clock outputs may be outputdirectly on any GPIO pin by setting the respective GPIO registers as described in "GPIO Control".

See "Clocking and Sample Rates" for more details of the WM1811A system clocking and for details of how to enable and configure the Frequency Locked Loops.

INTERRUPTS

The Interrupt Controller has multiple inputs. These include the GPIO input pins, the FLL Lock circuits, SRC Lock circuit, Microphone activity detection, Over-temperature indication and Digital FIFO error detection. Any combination of these inputs can be used to trigger an Interrupt Request (IRQ) event.

There is an Interrupt register field associated with each of the interrupt inputs. These fields are asserted whenever a logic edge is detected on the respective input. Some inputs are triggered on rising edges only; some are triggered on both edges, as noted in Table 84. The Interrupt register fields are held in Registers R1840 and R1841. The Interrupt flags can be polled at any time from these registers, or else in response to the Interrupt Request (IRQ) output being signalled via a GPIO pin.

All of the Interrupts are edge-triggered, as noted above. Many of these are triggered on both the rising and falling edges and, therefore, the Interrupt registers cannot indicate which edge has been detected. The "Raw Status" fields in Register R1842 provide readback of the current value of selected inputs to the Interrupt Controller. Note that the logic levels of any GPIO inputs can be read using the GPn_LVL registers, as described in Table 79.

Individual mask bits can select or deselect different functions from the Interrupt controller. These are listed within the Interrupt Status Mask registers, as described in Table 84. Note that the Interrupt register fields remain valid, even when masked, but the masked interrupts will not cause the Interrupt Request (IRQ) output to be asserted.

The Interrupt Request (IRQ) output represents the logical 'OR' of all the unmasked interrupts. The Interrupt register fields are latching fields and, once they are set, they are not reset until a '1' is written to the respective register bit(s). The Interrupt Request (IRQ) output is not reset until each of the unmasked interrupts has been reset.

De-bouncing of the GPIO inputs can be enabled using the register bits described in Table 79. Debouncing is also available on the Temperature Warning and Temperature Shutdown inputs to the Interrupt Controller, in order to avoid false detections - see Table 84 for the associated registers.

The Interrupt Request (IRQ) output can be globally masked by setting the IM_IRQ register. Under default conditions, the Interrupt Request (IRQ) is not masked.

The Interrupt Request (IRQ) flag may be output on a GPIO pin - see "General Purpose Input/Output".

The WM1811A Interrupt Controller circuit is illustrated in Figure 43. (Note that not all interrupt inputs are shown.) The associated control fields are described in Table 84.

Table 84 Interrupt Configuration

DIGITAL AUDIO INTERFACE

The WM1811A provides digital audio interfaces for inputting DAC data and outputting ADCor Digital Microphone data. Flexible routing options also allow digital audio to be switched or mixed between interfaces without involving any DAC or ADC.

The WM1811A provides two full audio interfaces, AIF1 and AIF2. A third interface, AIF3, supports Mono PCM digital audio paths to/from the AIF2 DSP functions. AIF3 can also be configured using multiplexers to provide alternate connections to AIF1 or AIF2.

The digital audio interfaces provide flexible connectivity with multiple processors (eg. Applications processor, Baseband processor and Wireless transceiver). A typical configuration is illustrated in Figure 44.

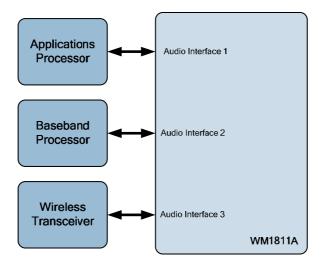

Figure 44 Typical AIF Connections

In the general case, the digital audio interface uses four pins:

- ADCDAT: ADC data output
- DACDAT: DAC data input
- LRCLK: Left/Right data alignment clock
- BCLK: Bit clock, for synchronisation

In master interface mode, the clock signals BCLK and LRCLK are outputs from the WM1811A. In slave mode, these signals are inputs, as illustrated below.

As an option (AIF1 only), a GPIO pin can be configured as the Left/Right clock for the ADC. In this case, the LRCLK pin is dedicated to the DAC, allowing the ADC and DAC to be clocked independently.

Four different audio data formats are supported each digital audio interface:

- Left justified
- Right justified
- I²S
- DSP mode

All four of these modes are MSB first. They are described in the following sections. Refer to the "Signal Timing Requirements" section for timing information.

Time Division Multiplexing (TDM) is available in all four data format modes. The WM1811A can be configured to transmit and receive in one of two timeslots.

Two variants of DSP mode are supported - 'Mode A' and 'Mode B'. Mono operation can be selected on either audio interface in both DSP modes. PCM operation is supported using the DSP mode.

MASTER AND SLAVE MODE OPERATION

The WM1811A digital audio interfaces can operate as a master or slave as shown in Figure 45 and Figure 46. The associated control bits are described in "Digital Audio Interface Control".

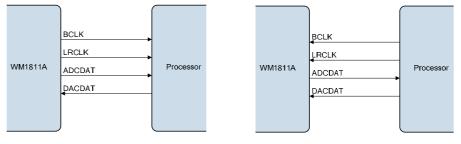

Figure 45 Master Mode

Figure 46 Slave Mode

OPERATION WITH TDM

Time division multiplexing (TDM) allows multiple devices to transfer data simultaneously on the same bus. The WM1811A ADCs and DACs support TDM in master and slave modes for all data formats and word lengths. TDM is enabled and configured using register bits defined in the "Digital Audio Interface Control" section.

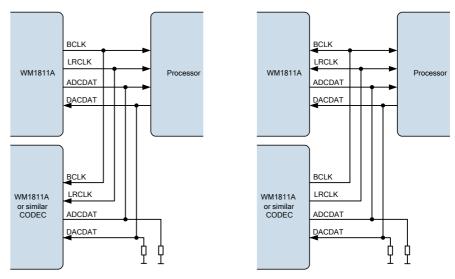

Figure 47 TDM with WM1811A as Master

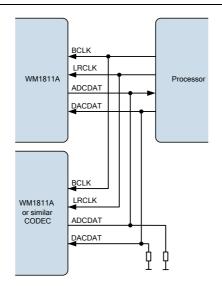

Figure 49 TDM with Processor as Master

Note: The WM1811A is a 24-bit device. If the user operates the WM1811A in 32-bit mode then the 8 LSBs will be ignored on the receiving side and not driven on the transmitting side. It is therefore recommended to add a pull-down resistor if necessary to the DACDAT line and the ADCDAT line in TDM mode.

AUDIO DATA FORMATS (NORMAL MODE)

The audio data modes supported by the WM1811A are described below. Note that the polarity of the BCLK and LRCLK signals can be inverted if required; the following descriptions all assume the default, non-inverted polarity of these signals.

In Right Justified mode, the LSB is available on the last rising edge of BCLK before a LRCLK transition. All other bits are transmitted before (MSB first). Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles after each LRCLK transition.

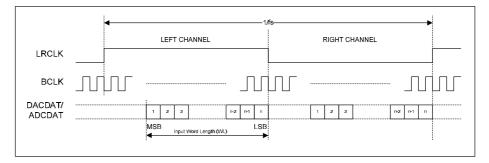

Figure 50 Right Justified Audio Interface (assuming n-bit word length)

In Left Justified mode, the MSB is available on the first rising edge of BCLK following a LRCLK transition. The other bits up to the LSB are then transmitted in order. Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles before each LRCLK transition.

Figure 51 Left Justified Audio Interface (assuming n-bit word length)

In I²S mode, the MSB is available on the second rising edge of BCLK following a LRCLK transition. The other bits up to the LSB are then transmitted in order. Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles between the LSB of one sample and the MSB of the next.

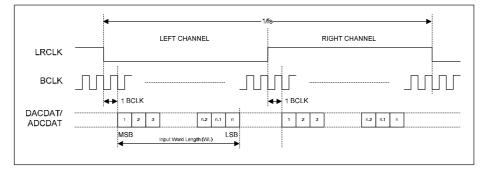

Figure 52 I2S Justified Audio Interface (assuming n-bit word length)

In DSP mode, the left channel MSB is available on either the 1st (mode B) or 2nd (mode A) rising edge of BCLK following a rising edge of LRCLK. Right channel data immediately follows left channel data. Depending on word length, BCLK frequency and sample rate, there may be unused BCLK cycles between the LSB of the right channel data and the next sample.

The selected mode (Mode A or Mode B) is determined by the AIFnDAC_LRCLK_INV bits for the AIFn digital input (playback) signal paths, and by the AIFnADC_LRCLK_INV bits for the AIFn digital output (record) signal paths.

Note that the DSP Mode is selected independently for the input/output paths of each digital audio interface.

In device master mode, the LRCLKoutput will resemble the frame pulse shown in Figure 53 and Figure 54. In device slave mode, Figure 55 and Figure 56, it is possible to use any length of frame pulse less than 1/fs, providing the falling edge of the frame pulse occurs greater than one BCLK period before the rising edge of the next frame pulse.

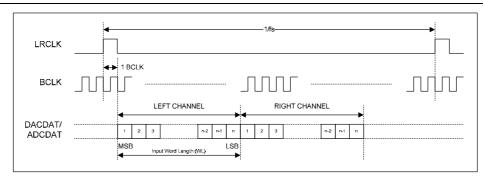

Figure 53 DSP Mode A (AIFnDAC_LRCLK_INV / AIFnADC_LRCLK_INV=0, Master)

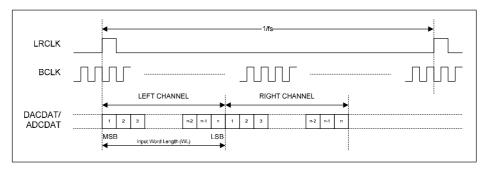

Figure 54 DSP B Mode (AIFnDAC_LRCLK_INV / AIFnADC_LRCLK_INV=1, Master)

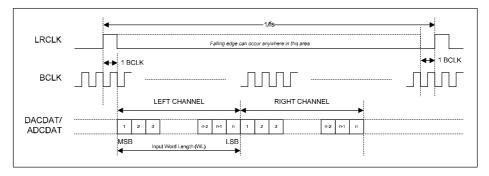

Figure 55 DSP Mode A(AIFnDAC_LRCLK_INV / AIFnADC_LRCLK_INV=0, Slave)

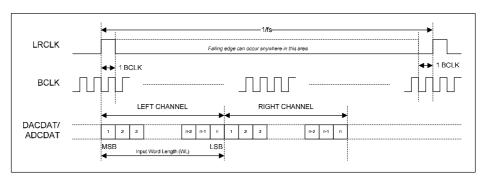

Figure 56 DSP Mode B (AIFnDAC_LRCLK_INV / AIFnADC_LRCLK_INV=1, Slave)

Mono mode operation is available in DSP interface mode. When Mono mode is enabled, the audio data is transmitted or received starting on either the 1st (mode B) or 2nd (mode A) rising edge of BCLK following a rising edge of LRCLK.

PCM operation is supported in DSP interface mode. WM1811A ADC data that is output on the Left Channel will be read as mono PCM data by the receiving equipment. Mono PCM data received by the WM1811A will be treated as Left Channel data. This data may be routed to the Left/Right DACs using the control fields described in the "Digital Mixing" and "Digital Audio Interface Control" sections.

AUDIO DATA FORMATS (TDM MODE)

TDM is supported in master and slave modes. All audio interface data formats support time division multiplexing (TDM) for ADC and DAC data.

On AIF1, the TDM format is enabled by register control (AIF1ADC_TDM and AIF1DAC_TDM for the output and input paths respectively). When TDM is enabled on AIF1, the data formats shown in Figure 57 to Figure 61 are always selected, and the WM1811A transmits or receives AIF1 data in one of the two available timeslots; the ADCDAT1 output is tri-stated when not outputting data.

Two AIF1 time slots are available (Slot 0 and Slot 1), selected by register bits AIF1ADC_TDM_CHAN and AIF1DAC_TDM_CHAN; these determine the active time slot for the ADC data and the DAC data respectively.

On AIF2, the TDM format is enabled by register control (AIF2ADC_TDM and AIF2DAC_TDM for the output and input paths respectively). When TDM is enabled on AIF2, the data formats shown in Figure 57 to Figure 61 are always selected, and the WM1811A transmits or receives AIF2 data in one of the two available timeslots; the ADCDAT2 output is tri-stated when not outputting data.

Two AIF2 time slots are available (Slot 0 and Slot 1), selected by register bits AIF2ADC_TDM_CHAN and AIF2DAC_TDM_CHAN; these determine the active time slot for the ADC data and the DAC data respectively.

When TDM is enabled, the ADCDAT pin will be tri-stated immediately before and immediately after data transmission, to allow another ADC device to drive this signal line for the remainder of the sample period. Note that it is important that two ADC devices do not attempt to drive the data pin simultaneously. A short circuit may occur if the transmission time of the two ADC devices overlap with each other. See "Audio Interface Timing" for details of the ADCDAT output relative to BCLK signal. Note that it is possible to ensure a gap exists between transmissions by setting the transmitted word length to a value higher than the actual length of the data. For example, if 32-bit word length is selected where only 24-bit data is available, then the WM1811A interface will tri-state after transmission of the 24-bit data, ensuring a gap after the WM1811A TDM slot.

When TDM is enabled, the BCLK frequency must be high enough to allow data from both time slots to be transferred. The relative timing of Slot 0 and Slot 1 depends upon the selected data format, as shown in Figure 57 to Figure 61.

DIGITAL AUDIO INTERFACE CONTROL

This section describes the configuration of the WM1811A digital audio interface paths.

Interfaces AIF1 and AIF2 can be configured as Master or Slave, or can be tri-stated. Each input and output signal path can be independently enabled or disabled. AIF output (digital record) and AIF input (digital playback) paths can use a common Left/Right clock, or can use separate clocks for mixed sample rates.

Interfaces AIF1 and AIF2 each support flexible formats, word-length, TDM configuration, channel swapping and input path digital boost functions. 8-bit companding modes and digital loopback is also possible.

A third interface, AIF3, supports Mono PCM digital audio paths to/from the AIF2 DSP functions. AIF3 can also be configured using multiplexers to provide alternate connections to AIF1 or AIF2. Note that AIF3 operates in Master mode only.

AIF1 - MASTER / SLAVE AND TRI-STATE CONTROL

The Digital Audio Interface AIF1 can operate in Master or Slave modes, selected by AIF1_MSTR. In Master mode, the BCLK1 and LRCLK1 signals are generated by the WM1811A when one or more AIF1 channels is enabled.

When AIF1_LRCLK_FRC or AIF1_CLK_FRC is set in Master mode, then LRCLK1 and ADCLRCLK1 are output at all times, including when none of the AIF1 audio channels is enabled. Note that LRCLK1 and ADCLRCLK1 are derived from BCLK1, and either an internal or external BCLK1 signal must also be present to generate LRCLK1 or ADCLRCLK1.

When AIF1_CLK_FRC is set in Master mode, then BCLK1is output at all times, including when none of the AIF1 audio channels is enabled.

The AIF1 interface can be tri-stated by setting the AIF1_TRI register. When this bit is set, then all of the AIF1 outputs are un-driven (high-impedance).Note that the ADCLRCLK1/GPI01 pin is a configurable pin which may take different functions independent of AIF1. The AIF1_TRI register only controls the ADCLRCLK1/GPI01 pin when its function is set to ADCLRCLK1. See "General Purpose Input/Output" to configure the GPI01 pin.

Table 85 AIF1 Master / Slave and Tri-state Control

AIF1 - SIGNAL PATH ENABLE

The AIF1 interface supports two input channels and two output channels. Each of the available channels can be enabled or disabled using the register bits defined in Table 86. These register controls are illustrated in Figure 66.

Table 86 AIF1 Signal Path Enable

AIF1 - BCLK AND LRCLK CONTROL

The BCLK1 frequency is controlled relative to AIF1CLK by the AIF1_BCLK_DIV divider. See "Clocking and Sample Rates" for details of the AIF1 clock, AIF1CLK.

The LRCLK1 frequency is controlled relative to BCLK1 by the AIF1DAC_RATE divider.

In Master mode, the LRCLK1 output is generated by the WM1811A when any of the AIF1 channels is enabled. (Note that, when GPIO1 is configured as ADCLRCLK1, then only the AIF1 DAC channels will cause LRCLK1 to be output.)

In Slave mode, the LRCLK1 output is disabled by default to allow another digital audio interface to drive this pin. It is also possible to force the LRCLK1 signal to be output, using the AIF1DAC_LRCLK_DIR or AIF1ADC_LRCLK_DIR register bits, allowing mixed master and slave modes. (Note that, when GPIO1 is configured as ADCLRCLK1, then only the AIF1DAC_LRCLK_DIR bit will force the LRCLK1 signal.)

When the GPIO1 pin is configured as ADCLRCLK1, then the ADCLRCLK1 frequency is controlled relative to BCLK1 by the AIF1ADC_RATE divider. In this case, the ADCLRCLK1 is dedicated to AIF1 output, and the LRCLK1 pin is dedicated to AIF1 input, allowing different sample rates to be supported in the two paths.

In Master mode, with GPIO1 pin configured as ADCLRCLK1, this output is enabled when any of the AIF1 ADC channels is enabled. The ADCLRCLK1 signal can also be enabled in Slave mode, using the AIF1ADC_LRCLK_DIR bit, allowing mixed master and slave modes.

When the GPIO1 pin is not configured as ADCLRCLK1, then the LRCLK1 signal applies to the ADC and DAC channels, at a rate set by AIF1DAC_RATE.

See "General Purpose Input/Output" for the configuration of GPIO1.Note that, in Ultrasonic (4FS) mode, the GPIO1 pin must be configured as ADCLRCLK1.

The BCLK1 output can be inverted using the AIF1_BCLK_INV register bit. The LRCLK1 and ADCLRCLK1 output (when selected) can be inverted using the AIF1DAC_LRCLK_INV and AIF1ADC_LRCLK_INV register controls respectively.

Note that in Slave mode, when BCLK1 is an input, the AIF1_BCLK_INV register selects the polarity of the received BCLK1 signal. Under default conditions, DACDAT1 input is captured on the rising edge of BCLK1, as illustrated in Figure 4. When AIF1_BCLK_INV = 1, DACDAT1 input is captured on the falling edge of BCLK1.

Table 87 AIF1 BCLK and LRCLK Control

AIF1 - DIGITAL AUDIO DATA CONTROL

The register bits controlling the audio data format, word length, left/right channel selection and TDM control for AIF1 are described in Table 88.

When TDM mode is enabled on AIF1, the WM1811A can transmit and receive audio data in Slot 0 or Slot 1. In this case, the ADCDAT1 output is tri-stated during the unused timeslot, allowing another device to transmit data on the same pin. See "Signal Timing Requirements" for the associated timing details.(Note that, when TDM is not enabled on AIF1, the ADCDAT1 output is driven logic '0' during the unused timeslot.)

In DSP mode, the left channel MSB is available on either the 1st (mode B) or 2nd (mode A) rising edge of BCLK following a rising edge of LRCLK (assuming default BCLK polarity).

When the AIF1DAC_LRCLK_INV bit is set in DSP mode, then DSP Mode B is selected for the AIF1 digital input (playback) signal path. When the AIF1DAC_LRCLK_INV bit is not set, then DSP Mode A is selected.

When the AIF1ADC_LRCLK_INV bit is set in DSP mode, then DSP Mode B is selected for the AIF1 digital output (record) signal path. When the AIF1ADC_LRCLK_INV bit is not set, then DSP Mode A is selected.

Note that the DSP Mode is selected independently for the input/output paths of each digital audio interface. Also note that the AIF1ADCLRCLK_INV bits remain valid even when the LRCLK signal is common for both paths. See Table 87 for details of the AIF1DAC_LRCLK_INV and AIF1ADC_LRCLK_INV register fields.

A digital gain function is available at the audio interface input path to boost the DAC volume when a small signal is received on DACDAT1. This is controlled using the AIF1DAC_BOOST register. To prevent clipping, this function should not be used when the boosted data is expected to be greater than 0dBFS.

Table 88 AIF1 Digital Audio Data Control

AIF1 - MONO MODE

AIF1 can be configured to operate in mono DSP mode by setting AIF1_MONO = 1 as described in Table 89. Note that mono mode is only supported in DSP mode, ie when AIF1_FMT = 11.

In mono mode, the Left channel data or the Right channel data may be selected for output on ADCDAT1. The selected channel is determined by the AIF1ADC1L_ENA and AIF1ADC1R_ENA bits. (If both bits are set, then the Right channel data is selected.)

In mono mode, the DACDAT1 input can be enabled on the Left and/or Right signal paths using the AIF1DAC1L_ENA and AIF1DAC1R_ENA bits. The mono input can be enabled on both paths at the same time if required.

Table 89 AIF1 Mono Mode Control

AIF1 - COMPANDING

The WM1811A supports A-law and μ -law companding on both transmit (ADC) and receive (DAC) sides of AIF1. This is configured using the register bits described inTable 90.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|-----------|---------|---------------------------------|
| R769 (0301h) | 4 | AIF1DAC_C | 0 | AIF1 Receive Companding Enable |
| AIF1 Control | | OMP | | 0 = Disabled |
| (2) | | | | 1 = Enabled |

| | 1 | AIF1ADC_C | 0 | AIF1 Transmit Companding Type |
| | 0 | OMPMODE | | 0 = µ-law |
| | | | | 1 = A-law |

Table 90 AIF1 Companding

Companding involves using a piecewise linear approximation of the following equations (as set out by ITU-T G.711 standard) for data compression:

 μ -law (where μ =255 for the U.S. and Japan):

| $F(x) = \ln(1 + \mu x) / \ln(1 + \mu)$ | } for -1 ≤ x ≤ 1 |
|--|------------------|
|--|------------------|

A-law (where A=87.6 for Europe):

| F(x) = A x / (1 + InA) | $for x \leq 1/A$ |
|---------------------------------------|-----------------------|
| $F(x) = (1 + \ln A x) / (1 + \ln A)$ | $for 1/A \le x \le 1$ |

The companded data is also inverted as recommended by the G.711 standard (all 8 bits are inverted for μ -law, all even data bits are inverted for A-law). The data will be transmitted as the first 8 MSBs of data.

Companding converts 13 bits (μ -law) or 12 bits (A-law) to 8 bits using non-linear quantization. This provides greater precision for low amplitude signals than for high amplitude signals, resulting in a greater usable dynamic range than 8 bit linear quantization. The companded signal is an 8-bit word comprising sign (1 bit), exponent (3 bits) and mantissa (4 bits).

AIF1 8-bit mode is selected whenever AIF1DAC_COMP=1 or AIF1ADC_COMP=1. The use of 8-bit data allows samples to be passed using as few as 8 BCLK1 cycles per LRCLK1 frame. When using DSP mode B, 8-bit data words may be transferred consecutively every 8 BCLK1 cycles.

AIF1 8-bit mode (without Companding) may be enabled by setting AIF1DAC_COMPMODE=1 or AIF1ADC_COMPMODE=1, when AIF1DAC_COMP=0 and AIF1ADC_COMP=0.

AIF1 - DIGITAL PULL-UP AND PULL-DOWN

The WM1811A provides integrated pull-up and pull-down resistors on each of the DACDAT1, LRCLK1 and BCLK1 pins. This provides a flexible capability for interfacing with other devices.

Each of the pull-up and pull-down resistors can be configured independently using the register bits described in Table 93. Note that if the Pull-up and Pull-down are both enabled for any pin, then the pull-up and pull-down will be disabled.

Table 93 AIF1 Digital Pull-Up and Pull-Down Control

AIF2 - MASTER / SLAVE AND TRI-STATE CONTROL

The Digital Audio Interface AIF2 can operate in Master or Slave modes, selected by AIF2_MSTR. In Master mode, the BCLK2 and LRCLK2 signals are generated by the WM1811A when one or more AIF2 channels is enabled.

When AIF2_LRCLK_FRC or AIF2_CLK_FRC is set in Master mode, then LRCLK2 is output at all times, including when none of the AIF2 audio channels is enabled. Note that LRCLK2 is derived from BCLK2, and either an internal or external BCLK2 signal must be present to generate LRCLK2.

When AIF2_CLK_FRC is set in Master mode, then BCLK2 is output at all times, including when none of the AIF2 audio channels is enabled.

The AIF2 interface can be tri-stated by setting the AIF2_TRI register. When this bit is set, then all of the AIF2 outputs are un-driven (high-impedance). The AIF2_TRI register only affects those pins which are configured for AIF2 functions; it does not affect pins which are configured for other functions.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

AIF2 - SIGNAL PATH ENABLE

The AIF2 interface supports two input channels and two output channels. Each of the available channels can be enabled or disabled using the register bits defined in Table 95. These register controls are illustrated in Figure 66.

Table 95 AIF2 Signal Path Enable

AIF2 - BCLK AND LRCLK CONTROL

The BCLK2 frequency is controlled relative to AIF2CLK by the AIF2_BCLK_DIV divider. See "Clocking and Sample Rates" for details of the AIF2 clock, AIF2CLK.

The LRCLK2 frequency is controlled relative to BCLK2 by the AIF2DAC_RATE divider.Note that the LRCLK2 signal is shared by the AIF2 input and AIF2 output paths; accordingly, the AIF2 input and AIF2 output must always operate at the same sample rate.

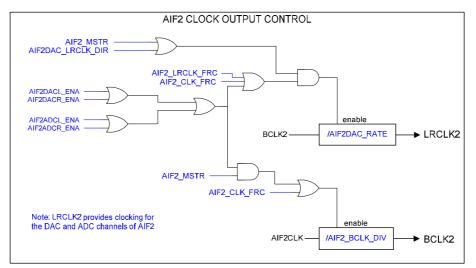

In Master mode, the LRCLK2 output is generated by the WM1811A when any of the AIF2 channels is enabled.

In Slave mode, the LRCLK2 output is disabled by default to allow another digital audio interface to drive this pin. It is also possible to force the LRCLK2 signal to be output, using the AIF2DAC_LRCLK_DIR register bit, allowing mixed master and slave modes.

The BCLK2 and LRCLK2 output can be inverted using the AIF2_BCLK_INV and AIF2DAC_LRCLK_INV register bits respectively.

Note that in Slave mode, when BCLK2 is an input, the AIF2_BCLK_INV register selects the polarity of the received BCLK2 signal. Under default conditions, DACDAT2 input is captured on the rising edge of BCLK2, as illustrated in Figure 4. When AIF2_BCLK_INV = 1, DACDAT2 input is captured on the falling edge of BCLK2.

The AIF2 clock generators are controlled as illustrated in Figure 65.

Table 96 AIF2 BCLK and LRCLK Control

AIF2 - DIGITAL AUDIO DATA CONTROL

The register bits controlling the audio data format, word length, left/right channel selection and TDM control for AIF2 are described in Table 97.

When TDM mode is enabled on AIF2, the WM1811A can transmit and receive audio data in Slot 0 or Slot 1. In this case, the ADCDAT2 output is tri-stated during the unused timeslot, allowing another device to transmit data on the same pin. See "Signal Timing Requirements" for the associated timing details.(Note that, when TDM is not enabled on AIF2, the ADCDAT2 output is driven logic '0' during the unused timeslot.)

In DSP mode, the left channel MSB is available on either the 1st (mode B) or 2nd (mode A) rising edge of BCLK following a rising edge of LRCLK (assuming default BCLK polarity).

When the AIF2DAC_LRCLK_INV bit is set in DSP mode, then DSP Mode B is selected for the AIF2 digital input (playback) signal path. When the AIF2DAC_LRCLK_INV bit is not set, then DSP Mode A is selected.

When the AIF2ADC_LRCLK_INV bit is set in DSP mode, then DSP Mode B is selected for the AIF2 digital output (record) signal path. When the AIF2ADC_LRCLK_INV bit is not set, then DSP Mode A is selected.

Note that the DSP Mode is selected independently for the input/output paths of each digital audio interface. The LRCLK signal is common for both paths so, for typical applications, the AIF2DAC_LRCLK_INV and AIF2ADC_LRCLK_INV bits should be set to the same value. The AIF2DAC_LRCLK_INV bit is defined in Table 96.

A digital gain function is available at the audio interface input path to boost the DAC volume when a small signal is received on DACDAT2. This is controlled using the AIF2DAC_BOOST register. To prevent clipping, this function should not be used when the boosted data is expected to be greater than 0dBFS.

Table 97 AIF2 Digital Audio Data Control

AIF2 - MONO MODE

AIF2 can be configured to operate in mono DSP mode by setting AIF2_MONO = 1 as described in Table 98. Note that mono mode is only supported in DSP mode, ie when AIF2_FMT = 11.

In mono mode, the Left channel data or the Right channel data may be selected for output on ADCDAT2. The selected channel is determined by the AIF2ADCL_ENA and AIF2ADCR_ENA bits. (If both bits are set, then the Right channel data is selected.)

In mono mode, the DACDAT2 input can be enabled on the Left and/or Right signal paths using the AIF2DACL_ENA and AIF2DACR_ENA bits. The mono input can be enabled on both paths at the same time if required.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|-------------------------------------|-----|-----------|---------|---|
| R785 (0311h) AIF2 Control (2) | 8 | AIF2_MONO | 0 | AIF2 DSP Mono Mode 0 = Disabled 1 = Enabled Note that Mono Mode is only supported when AIF2_FMT = 11. |

Table 98 AIF2 Mono Mode Control

AIF2 - COMPANDING

The WM1811A supports A-law and μ -law companding on both transmit (ADC) and receive (DAC) sides of AIF2. This is configured using the register bits described in Table 99.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

For more details on Companding, see the Audio Interface AIF1 description above.

Table 99 AIF2 Companding

AIF2 - LOOPBACK

The AIF2 interface can provide a Loopback option. When the AIF2_LOOPBACK bit is set, then AIF2 digital audio output is routed to the AIF2 digital audio input. The normal input (DACDAT2) is not used when AIF2 Loopback is enabled.

Table 100 AIF2 Loopback

AIF2 - DIGITAL PULL-UP AND PULL-DOWN

The WM1811A provides integrated pull-up and pull-down resistors on each of the DACDAT2, DACLRCLK2 and BCLK2 pins. This provides a flexible capability for interfacing with other devices.

Each of the pull-up and pull-down resistors can be configured independently using the register bits described inTable 101.Note that if the Pull-up and Pull-down are both enabled for any pin, then the pull-up and pull-down will be disabled.

Table 101 AIF2 Digital Pull-Up and Pull-Down Control

AIF3 - SIGNAL PATH CONFIGURATION AND TRI-STATE CONTROL

The AIF3 interface provides Mono PCM digital audio paths to/from the AIF2 DSP functions. The AIF3 interface can also support stereo digital audio paths via multiplexers to provide alternate connections to AIF1 or AIF2. The relevant multiplexers are illustrated in Figure 66.

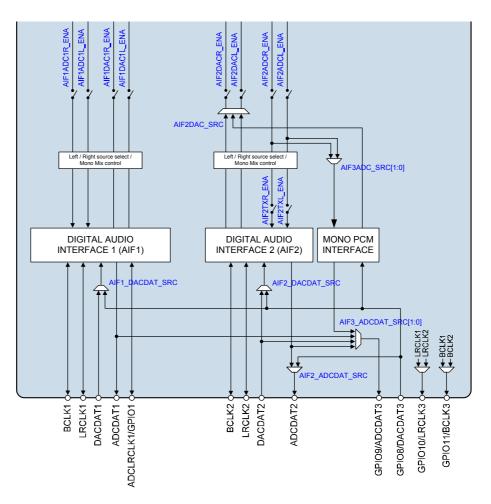

Figure 66 Audio Interface AIF3 Configuration

Note that all of the AIF3 connections are supported on pins which also provide GPIO functions. These pins must be configured as AIF functions when used as audio interface pins. See "General Purpose Input/Output".

The GPIO8 pin supports the DACDAT3 function, which provides the input to the AIF3 Mono PCM interface.

When AIF3 Mono PCM input is used, this must be configured as an input to the AIF2 input paths using the AIF2DAC_SRC register as described in Table 102. The AIF3 Mono input may be selected on either channel (Left or Right), with AIF2 input enabled on the opposite channel at the same time.

When AIF3 Mono PCM input is used, the AIF2 input paths must be enabled using the AIF2DACR_ENA and AIF2DACL_ENA register bits defined in Table 95.

The DACDAT3 input pin can also be used as an input (mono or stereo) to AIF1 or AIF2. The data input source for AIF1 is selected using the AIF1_DACDAT_SRC register. The data input source for AIF2 is selected using the AIF2_DACDAT_SRC register.

The DACDAT3 input pin can also be routed to the ADCDAT2 output. The ADCDAT2 source is selected using the AIF2_ADCDAT_SRC register.

The GPIO9 pin supports the ADCDAT3 function, which supports the output from the AIF3 Mono PCM interface. The source for the ADCDAT3 pin is selected using the AIF3_ADCDAT_SRC register.

When AIF3 Mono PCM output is used, the data source must be configured using the AIF3ADC_SRC register; this selects either the Left or Right AIF2 output paths as the data source.

When AIF3 Mono PCM output is used, the AIF2 output paths must be enabled using the AIF2ADCR_ENA and AIF2ADCL_ENA register bits. Note that, if AIF3 Mono PCM output is required and AIF2 output is not used, then the AIF2 output can be disabled using the AIF2TXL_ENA and AIF2TXR_ENA registers.See Table 95 for details of these registers.

The ADCDAT3 pin can also be used as an alternate data output (mono or stereo) from AIF1 or AIF2, or can be connected to the DACDAT2 data input.

The AIF3 interface can be tri-stated by setting the AIF3_TRI register. When this bit is set, then all of the AIF3 outputs are un-driven (high-impedance). The AIF3_TRI register only affects those pins which are configured for AIF3 functions; it does not affect pins which are configured for other functions.

Table 102 AIF3 Signal Path Configuration

AIF3 - BCLK AND LRCLK CONTROL

The GPIO10 pin supports the LRCLK3 function. When configured as LRCLK3, this pin outputs the LRCLK signal from AIF1 or AIF2. The applicable AIF source is determined automatically as defined in Table 103. Note that the LRCLK3 signal is also controlled by the logic illustrated in Figure 62 (AIF1) or Figure 65 (AIF2), depending on the selected AIF source.

The GPIO11 pin supports the BCLK3 function. When configured as BCLK3, this pin outputs the BCLK signal from AIF1 or AIF2. The applicable AIF source is determined automatically as defined in Table 103. Note that the BCLK3 signal is also controlled by the logic illustrated in Figure 62 (AIF1) or Figure 65 (AIF2), depending on the selected AIF source.

| CONDITION | DESCRIPTION |
|---|--|
| AIF1_DACDAT_SRC = 1 | AIF1 selected as BCLK3 / LRCLK3 source |
| (DACDAT3 selected as AIF1 data input) | |
| or | |
| AIF3_ADCDAT_SRC[1:0] = 00 (AIF1 data output selected on ADCDAT3) | |
| All other conditions | AIF2 selected as BCLK3 / LRCLK3 source |

Table 103 BCLK3 / LRCLK3 Configuration

The LRCLK3 output can be inverted by setting the AIF3_LRCLK_INV register. Note that AIF3 operates in Master mode only.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|-----------|---------|--|
| R800 (0320h) | 7 | AIF3_LRCL | 0 | Right, left and I ² S modes – LRCLK3 polarity |
| AIF3 Control | | K_INV | | 0 = normal LRCLK3 polarity |

| | | | | DSP Mode – mode A/B select |
| | | | | 0 = MSB is available on 2nd BCLK3 rising edge after LRCLK3 rising edge (mode A) |
| | | | | 1 = MSB is available on 1st BCLK3 rising edge after LRCLK3 rising edge (mode B) |

Table 104 AIF3 LRCLK Control

AIF3 - DIGITAL AUDIO DATA CONTROL

The register bits controlling the AIF3Mono PCM interface are described in Table 105.

Note that these registers control the AIF3 Mono PCM interface only; they are not applicable to the ADCDAT3 and DACDAT3 signal paths when these pins are selected as alternate inputs to the AIF1 or AIF2 interfaces.

The audio data format for AIF3 is set the same as AIF2; this is controlled using the AIF2_FMT register, as described in see Table 97.

In DSP mode, the AIF3 Mono channel MSB is available on either the 1st (mode B) or 2nd (mode A) rising edge of BCLK following a rising edge of LRCLK. The applicable DSP mode is selected using the AIF3_LRCLK_INV bit, as described in Table 104.

In Left justified, Right justified and I2S modes, the AIF3 Mono interface data is transmitted and received in the Left channel data bits of the ADCDAT3 and DACDAT3 channels.

A digital gain function is available at the audio interface input path to boost the DAC volume when a small signal is received on DACDAT3. This is controlled using the AIF3DAC_BOOST register. To prevent clipping, this function should not be used when the boosted data is expected to be greater than 0dBFS.

Table 105 AIF3 Digital Audio Data Control

AIF3 - COMPANDING

The WM1811A supports A-law and μ -law companding on both transmit (ADC) and receive (DAC) sides of AIF3. This is configured using the register bits described in Table 106.

Note that these registers control the AIF3 Mono PCM interface only; they are not applicable to the ADCDAT3 and DACDAT3 signal paths when these pins are selected as alternate inputs to the AIF1 or AIF2 interfaces.

For more details on Companding, see the Audio Interface AIF1 description above.

Table 106 AIF3 Companding

AIF3 - LOOPBACK

The AIF3 interface can provide a Loopback option. When the AIF3_LOOPBACK bit is set, then AIF3 Mono PCM output is routed to the AIF3Mono PCM input. The normal input (DACDAT3) is not used when AIF3 Loopback is enabled.

Table 107 AIF3 Loopback

CLOCKING AND SAMPLE RATES

The WM1811A requires a clock for each of the Digital Audio Interfaces (AIF1 and AIF2). These may be derived from a common clock reference, or from independent references. Under typical clocking configurations, many commonly-used audio sample rates can be derived directly from the external reference; for additional flexibility, the WM1811A incorporates two Frequency Locked Loop (FLL) circuits to perform frequency conversion and filtering.

External clock signals may be connected via MCLK1 and MCLK2. In AIF Slave modes, the BCLK or LRCLK signals may be used as a reference for the AIF clocks.

The WM1811A performs stereo full-duplex sample rate conversion between the audio interfaces AIF1 and AIF2, enabling digital audio to be routed between the interfaces, and asynchronous audio data to be mixed together. See "Sample Rate Conversion" for further details.

In AIF Slave modes, it is important to ensure the applicable AIF clock (AIF1CLK or AIF2CLK) is synchronised with the associated external LRCLK. This can be achieved by selecting an MCLK input that is derived from the same reference as the LRCLK, or can be achieved by selecting the external BCLK or LRCLK signals as a reference input to one of the FLLs, as a source for the AIF clock.

If the AIF clock is not synchronised with the LRCLK, then clicks arising from dropped or repeated audio samples will occur, due to the inherent tolerances of multiple, asynchronous, system clocks. See "Applications Information" for further details on valid clocking configurations.

Clocking for the Audio Interfaces is provided by AIF1CLK and AIF2CLK for AIF1 and AIF2 respectively. An additional internal clock, SYSCLK is derived from either AIF1CLK or AIF2CLK in order to support the DSP core functions, Charge Pump, Class D switching amplifier, DC servo control and other internal functions.

The following operating limits must be observed when configuring the WM1811A clocks. Failure to observe these limits will result in degraded performance and/or incorrect system functionality. Latency in the WM1811A signal paths is reduced at high SYSCLK frequencies; power consumption is reduced at low SYSCLK frequencies.

- SYSCLK ≤ 12.5MHz
- SYSCLK ≥4.096MHz
- SYSCLK ≥256 x fs (where fs = fastest audio sample rate in use)
- AIF1CLK ≤ 12.5MHz
- AIF1CLK ≥ 256 x AIF1 sample rate (AIF1_SR)
- AIF2CLK \leq 12.5MHz
- AIF2CLK ≥ 256 x AIF2 sample rate (AIF2_SR)

Note that, if DAC_OSR128 = 0 and ADC_OSR128 = 0, then a slower SYSCLK frequency is possible; in this case, the requirement is SYSCLK \geq 2.048MHz.

Note that, under specific operating conditions, clocking ratios of 128 x fs and 192 x fs are possible; this is described in the "Digital to Analogue Converter (DAC)" section.

The SYSCLK frequency must be \geq 256 x fs, (where fs is the faster rate of AIF1_SR or AIF2_SR). The SYSCLK frequency is derived from AIF1CLK or AIF2CLK, as selected by the SYSCLK_SRC register (see Table 112).

Note that the bandwidth of the digital audio mixing paths will be determined by the sample rate of whichever AIF is selected as the SYSCLK source. When using only one audio interface, the active interface should be selected as the SYSCLK source. For best audio performance when using AIF1 and AIF2 simultaneously, the SYSCLK source must select the AIF with the highest sample rate (AIFn_SR).

The AIF*n*CLK / fs ratio is the ratio of AIF*n*CLK to the AIF*n* sample rate, where '*n*' identifies the applicable audio interface AIF1 or AIF2. The AIF clocking ratio and sample rate are set by the AIF*n*CLK_RATE and AIF*n*_SR register fields, defined in Table 109 and Table 111.

Note that, in the case of mixed input/output path sample rates (supported on AIF1 only), then AIF*n*CLK_RATE and AIF*n*_SR are set according to the higher of the two sample rates.

The clocking configuration for AIF1CLK, AIF2CLK andSYSCLK illustrated in Figure 67.The SYSCLK_SRC register is defined in Table 112.

The WM1811A provides integrated pull-up and pull-down resistors on the MCLK1 and MCLK2 pins. This provides a flexible capability for interfacing with other devices. This is configured as described in Table 112. Note that if the Pull-up and Pull-down are both enabled for any pin, then the pull-up and pull-down will be disabled.

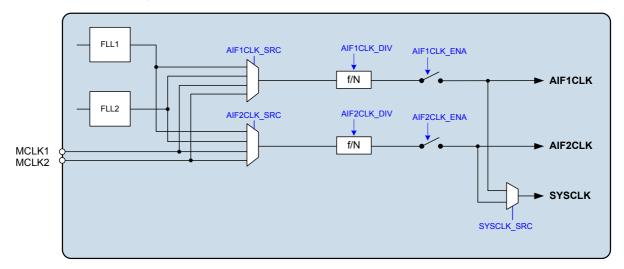

Figure 67 Audio Interface Clock Control

AIF1CLK ENABLE

The AIF1CLK_SRC register is used to select the AIF1CLK source. The source may be MCLK1, MCLK2, FLL1 or FLL2. If either of the Frequency Locked Loops is selected as the source, then the FLL(s) must be enabled and configured as described later.

The AIF1CLK clock may be adjusted by the AIF1CLK_DIV divider, which provides a divide-by-two option. The selected source may also be inverted by setting the AIF1CLK_INV bit.

The maximum AIF1CLK frequency is specified in the "Electrical Characteristics" section. Note that, when AIF1CLK_DIV = 1, the maximum frequency limit applies to the divided-down AIF1CLK frequency.

The AIF1CLK is enabled by the register bit AIF1CLK_ENA. This bit should be set to 0 when reconfiguring the clock sources. It is not recommended to change AIF1CLK_SRC while the AIF1CLK_ENA bit is set.

Table 108 AIF1CLK Enable

AIF1 CLOCKING CONFIGURATION

The WM1811A supports a wide range of standard audio sample rates from 8kHz to 96kHz. The AIF1 clocking configuration is selected using 4 control fields, which are set according to the required AIF digital audio sample rate, and the ADC/DAC clocking rate.

The AIF1_SR register is set according to the AIF1 sample rate. Note that 88.2kHz and 96kHz modes are supported for AIF1 input (DAC playback) only.

The AIF1CLK_RATE register is set according to the ratio of AIF1CLK to the AIF1 sample rate. Note that there are some restrictions on the supported clocking ratios, depending on the selected sample rate and operating conditions. The supported configurations are detailed in the "Digital Microphone Interface", "Analogue to Digital Converter (ADC)" and "Digital to Analogue Converter (DAC)" sections, according to each applicable function.

The AIF1 audio interface can support different sample rates for the input data (DAC path) and output data (ADC path) simultaneously. In this case, the AIF1_SR and AIF1CLK_RATE fields should be set according to the faster of the two sample rates.

When different sample rates are used for input data (DAC path) and output data (ADC path), the clocking of the slower path is set using AIF1DAC_DIV (if the AIF input path has the slower sample rate) or AIF1ADC_DIV (if the AIF output path has the slower sample rate). The appropriate divider is set according to the ratio of the two sample rates.

For example, if AIF1 input uses 48kHz sample rate, and AIF1 output uses 8kHz, then AIF1ADC_DIV should be set to 110b (divide by 6).

Note that the audio interface cannot support every possible combination of input and output sample rate simultaneously, but only where the ratio of the sample rates matches the available AIF1ADC_DIV or AIF1DAC_DIV divider settings.

Note that the WM1811A performs sample rate conversion, where necessary, to provide digital mixing and interconnectivity between the Audio Interfaces and the DSP Core functions. One stereo Sample Rate Converter (SRC) is provided for audio input; a second stereo SRC is provided for audio output. Each SRC is automatically configured on AIF1 or AIF2, depending on the selected Clocking and Sample Rate settings. The WM1811A cannot support configurations that would require SRC on the input or output paths of both interfaces simultaneously. See "Sample Rate Conversion" for further details.

AIF2 CLOCKING CONFIGURATION

The WM1811A supports a wide range of standard audio sample rates from 8kHz to 96kHz. The AIF2 clocking configuration is selected using 2control fields, which are set according to the required AIF digital audio sample rate, and the ADC/DAC clocking rate.

The AIF2_SR register is set according to the AIF2 sample rate. Note that 88.2kHz and 96kHz modes are supported for AIF2 input (DAC playback) only.

The AIF2CLK_RATE register is set according to the ratio of AIF2CLK to the AIF2 sample rate. Note that there are some restrictions on the supported clocking ratios, depending on the selected sample rate and operating conditions. The supported configurations are detailed in the "Digital Microphone Interface", "Analogue to Digital Converter (ADC)" and "Digital to Analogue Converter (DAC)" sections, according to each applicable function.

The AIF2 audio interface cannot support different sample rates for the input data (DAC path) and output data (ADC path) simultaneously. The AIF2_SR register sets the sample rate for both paths.

Note that the WM1811A performs sample rate conversion, where necessary, to provide digital mixing and interconnectivity between the Audio Interfaces and the DSP Core functions. One stereo Sample Rate Converter (SRC) is provided for audio input; a second stereo SRC is provided for audio output. Each SRC is automatically configured on AIF1 or AIF2, depending on the selected Clocking and Sample Rate settings. The WM1811A cannot support configurations that would require SRC on the input or output paths of both interfaces simultaneously. See "Sample Rate Conversion" for further details.

Table 111 AIF2 Clocking Configuration

MISCELLANEOUS CLOCK CONTROLS

SYSCLK provides clocking for many of the WM1811A functions. SYSCLK clock is required to support DSP Core functions and also the Charge Pump, Class D switching amplifier, DC servo control and other internal functions.

The SYSCLK_SRC register is used to select the SYSCLK source. The source may be AIF1CLK or AIF2CLK, as illustrated in Figure 68. Note that the bandwidth of the digital audio mixing paths will be determined by the sample rate of whichever AIF is selected as the SYSCLK source. When using only one audio interface, the active interface should be selected as the SYSCLK source. For best audio performance when using AIF1 and AIF2 simultaneously, the SYSCLK source must select the AIF with the highest sample rate (AIFn_SR).

The AIF1 DSP processing clock is derived from SYSCLK, and enabled by AIF1DSPCLK_ENA.

The AIF2 DSP processing clock is derived from SYSCLK, and enabled by AIF2DSPCLK_ENA.

The clocking of the WM1811A ADC, DAC, digital mixer and digital microphone functions is enabled by setting SYSDSPCLK_ENA. See "Digital Microphone Interface" for details of the DMICCLK frequency.

Two modes of ADC / Digital Microphone operation can be selected using the ADC_OSR128 bit. This bit is enabled by default, giving best audio performance. De-selecting this bit provides a low power alternative setting.

A high performance mode of DAC operation can be selected by setting the DAC_OSR128 bit. When the DAC_OSR128 bit is set, the audio performance is improved, but power consumption is also increased.

A clock is required for the Charge Pump circuit when the ground-referenced headphone outputs (HPOUT1L and HPOUT1R) are enabled. The Charge Pump clock is derived from SYSCLK whenever the Charge Pump is enabled. The Charge Pump clock division is configured automatically.

A clock is required for the Class D speaker driver circuit when the speaker outputs (SPKOUTL and SPKOUTR) are enabled. The Class D clock is derived from SYSCLK whenever these outputs are enabled in Class D mode. The Class D clock division is configured automatically. See "Analogue Outputs" for details of the Class D switching frequency.

A clock output (OPCLK) derived from SYSCLK may be output on a GPIO pin. This clock is enabled by register big OPCLK_ENA, and its frequency of this clock is controlled by OPCLK_DIV. See General Purpose Input/Output" to configure a GPIO pin for this function.

A slow clock (TOCLK) is derived internally in order to control volume update timeouts when the zerocross option is selected. This clock is enabled by register bit TOCLK_ENA, and its frequency is controlled by TOCLK_DIV.

A de-bounce control is provided for GPIO inputs and for other functions that may be selected as GPIO outputs. The de-bounced clock frequency is controlled by DBCLK_DIV.

The WM1811A generates a 256kHz clock for internal functions; TOCLK and DBCLK are derived from this 256kHz clock. In order to generate this clock correctly when SYSCLK_SRC = 0, valid settings are required for AIF1_SR and AIF1CLK_RATE. To generate this clock correctly when SYSCLK_SRC = 1, valid settings are required for AIF2_SR and AIF2CLK_RATE.

The WM1811A Clocking is illustrated in Figure 68.

Table 112 System Clocking

BCLK AND LRCLK CONTROL

The digital audio interfaces (AIF1 and AIF2) use BCLK and LRCLK signals for synchronisation. In master mode, these are output signals, generated by the WM1811A. In slave mode, these are input signals to the WM1811A. It is also possible to support mixed master/slave operation.

The BCLK and LRCLK signals are controlled as illustrated in Figure 69. See the "Digital Audio Interface Control" section for further details of the relevant control registers.

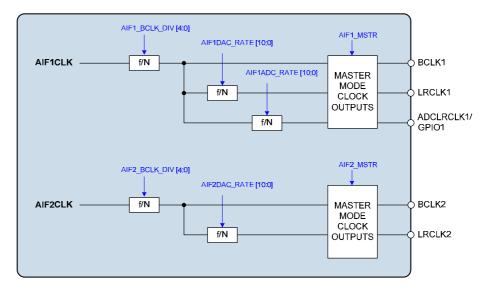

Figure 69 BCLK and LRCLK Control

CONTROL INTERFACE CLOCKING

Register map access is possible with or without a system clock. Clocking is provided from SYSCLK; the SYSCLK_SRC register selects either AIF1CLK or AIF2CLK as the applicable SYSCLK source.

When AIF1CLK is the SYSCLK source (ie. SYSCLK_SRC = 0), and AIF1CLK_ENA = 1, then an active clock source for AIF1CLK must be present for control interface clocking. If the AIF1CLK source is stopped, then AIF1CLK_ENA must be set to 0 for control register access.

When AIF2CLK is the SYSCLK source (ie. SYSCLK_SRC = 1), and AIF2CLK_ENA = 1, then an active clock source for AIF2CLK must be present for control interface clocking. If the AIF2CLK source is stopped, then AIF2CLK_ENA must be set to 0 for control register access.

FREQUENCY LOCKED LOOP (FLL)

Two integrated FLLs are provided to support the clocking requirements of the WM1811A. These can be enabled and configured independently according to the available reference clocks and the application requirements. The reference clock may be a high frequency (eg. 12.288MHz) or low frequency (eg. 32.768kHz).

The FLL is tolerant of jitter and may be used to generate a stable AIF clock from a less stable input reference. The FLL characteristics are summarised in "Electrical Characteristics". Note that the FLL can be used to generate a free-running clock in the absence of an external reference source. This is described in the "Free-Running FLL Clock" section below.

The input reference for FLL1 is selected using FLL1_REFCLK_SRC. The available options are MCLK1, MCLK2, BCLK1 or LRCLK1. The input reference for FLL2 is selected using FLL2_REFCLK_SRC. The available options are MCLK1, MCLK2, BCLK2 or LRCLK2.

The FLLs can be bypassed using the FLL1_BYP or FLL2_BYP registers. This allows the BCLK*n* clock to be used as the AIF*n*CLK reference, without enabling the respective FLL.

The FLL input reference and bypass configurations are illustrated in Figure 70.

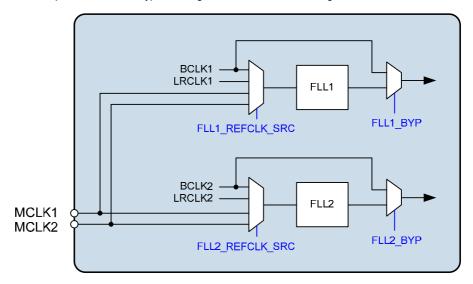

Figure 70 FLL Input Reference Selection

The following description is applicable to FLL1 and FLL2. The associated register control fields are described in Table 115 for FLL1 and Table 116 for FLL2.

The FLL control registers are illustrated in Figure 71.

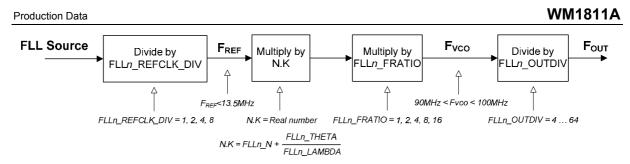

Figure 71 FLL Configuration

The FLL is enabled using the FLLn_ENA register bit (where n = 1 for FLL1 and n = 2 for FLL2). Note that the other FLL registers should be configured before enabling the FLL; the FLLn_ENA register bit should be set as the final step of the FLLn enable sequence.

When changing FLL settings, it is recommended that the digital circuit be disabled via FLL*n_*ENA and then re-enabled after the other register settings have been updated. When changing the input reference frequency F_{REF} , it is recommended that the FLL be reset by setting FLL*n_*ENA to 0.

The field FLL*n*_REFCLK_DIV provides the option to divide the input reference (MCLK, BCLK or LRCLK) by 1, 2, 4 or 8. This field should be set to bring the reference down to 13.5MHz or below. For best performance, it is recommended that the highest possible frequency - within the 13.5MHz limit - should be selected.

The FLL output frequency is directly determined from FLLn_FRATIO, FLLn_OUTDIV and the real number represented by N.K.

The integer value, N, is held in the FLL n_N register field. The fractional portion, K, is determined by the ratio FLL n_T HETA / FLL n_L AMBDA.

Note that the FLLn_EFS_ENA register bit must be enabled in fractional mode (ie. whenever FLLn_THETA > 0).

The FLL output frequency is generated according to the following equation:

 $F_{OUT} = (F_{VCO} / FLLn_OUTDIV)$

The FLLoperating frequency, F_{VCO} is set according to the following equation:

F_{VCO} = (F_{REF} x N.K x FLL*n*_FRATIO)

F_{REF} is the input frequency, as determined by FLLn_REFCLK_DIV.

F_{VCO} must be in the range 90-100 MHz. Frequencies outside this range cannot be supported.

Note that the output frequencies that do not lie within the ranges quoted above cannot be guaranteed across the full range of device operating conditions.

In order to follow the above requirements for F_{VCO} , the value of FLLn_OUTDIV should be selected according to the desired output F_{OUT} . The divider, FLLn_OUTDIV, must be set so that F_{VCO} is in the range 90-100MHz. The available divisions are integers from 4 to 64. Some typical settings of FLLn_OUTDIV are noted in Table 113.

| OUTPUT FREQUENCY Fout | FLLn_OUTDIV |
|------------------------|-----------------------|
| 1.875 MHz - 2.0833 MHz | 101111 (divide by 48) |
| 2.8125 MHz - 3.125 MHz | 011111 (divide by 32) |
| 3.75 MHz - 4.1667 MHz | 010111 (divide by 24) |
| 5.625 MHz - 6.25 MHz | 001111 (divide by 16) |
| 11.25 MHz - 12.5 MHz | 000111 (divide by 8) |
| 18 MHz - 20 MHz | 000100 (divide by 5) |
| 22.5 MHz - 25 MHz | 000011 (divide by 4) |

Table 113 Selection of FLLn_OUTDIV

| The value of FLL <i>n</i> FRATIO should be selected as described in Table 114. |
|--|
|--|

| REFERENCE FREQUENCY FREF | FLLn_FRATIO |
|--------------------------|-------------------|
| 1MHz - 13.5MHz | 0h (divide by 1) |
| 256kHz - 1MHz | 1h (divide by 2) |
| 128kHz - 256kHz | 2h (divide by 4) |
| 64kHz - 128kHz | 3h (divide by 8) |
| Less than 64kHz | 4h (divide by 16) |

Table 114 Selection of FLLn_FRATIO

In order to determine the remaining FLL parameters, the FLL operating frequency, F_{VCO} , must be calculated, as given by the following equation:

F_{VCO} = (F_{OUT} x FLL*n*_OUTDIV)

The value of N.K can then be determined as follows:

N.K = F_{VCO} / (FLL*n*_FRATIO x F_{REF})

Note that, in the above equations:

FLLn_OUTDIV is the F_{OUT} clock ratio.

 F_{REF} is the input frequency, after division by FLL_REFCLK_DIV, where applicable.

FLLn_FRATIO is the F_{VCO} clock ratio (1, 2, 4, 8 or 16).

The value of N is held in the FLLn_N register field.

The value of K is determined by the ratio FLL*n*_THETA / FLL*n*_LAMBDA.

The FLL n_N , FLL n_T HETA and FLL n_L AMBDA fields are all coded as integers (LSB = 1).

In Fractional Mode (FLLn_THETA > 0 and FLLn_EFS_ENA = 1), the register fields FLLn_THETA and FLLn_LAMBDA can be calculated as follows:

Calculate GCD(FLL) using the 'Greatest Common Denominator' function:

 $GCD(FLL) = GCD(FLLn_FRATIO \times F_{REF}, F_{VCO})$

where GCD(x, y) is the greatest common denominator of x and y

Next, calculate FLL*n*_THETA and FLL*n*_LAMBDA using the following equations:

 $FLLn_THETA = (F_{VCO} - (FLLn_N x FLLn_FRATIO x F_{REF})) / GCD(FLL)$

 $FLLn_LAMBDA = (FLLn_FRATIO \times F_{REF}) / GCD(FLL)$

Note that, in Fractional Mode, the values of FLL*n*_THETA and FLL*n*_LAMBDA must be co-prime (ie. not divisible by any common integer). The calculation above ensures that the values will be co-prime.

The value of K must be a fraction less than 1 (ie. FLLn_THETA must be less than FLLn_LAMBDA).

The FLL1 control registers are described in Table 115. The FLL2 control registers are described in Table 116. Example settings for a variety of reference frequencies and output frequencies are shown in Table 118.

Table 116 FLL2 Register Map

FREE-RUNNING FLL CLOCK

The FLL can generate a clock signal even when no external reference is available. However, it should be noted that the accuracy of this clock is reduced, and a reference source should always be used where possible. The free-running FLL modes are not sufficiently accurate for hi-fi ADC or DAC operations, but are suitable for clocking most other functions, including the Charge Pump, DC Servo and Class D loudspeaker driver. The free-running FLL operation is ideal for clocking the accessory detection function during low-power standby operating conditions (see "External Accessory Detection").

If an accurate reference clock is initially available, then the FLL should be configured as described above. The FLL will continue to generate a stable output clock after the reference input is stopped or disconnected.

If no reference clock is available at the time of starting up the FLL, then an internal clock frequency of approximately 12MHz can be generated by implementing the following sequence:

- Enable the FLL Analogue Oscillator (FLLn_OSC_ENA = 1)
- Set the F_{OUT} clock divider to divide by 8 (FLLn_OUTDIV = 000111)
- Configure the oscillator frequency by setting FLLn_FRC_NCO = 1 and FLLn_FRC_NCO_VAL = 19h

Note that the free-running FLL mode is not suitable for hi-fi CODEC applications. In the absence of any reference clock, the FLL output is subject to a very wide tolerance; see "Electrical Characteristics" for details of the FLL accuracy.

Note that the free-running FLL clock is selected as SYSCLK using the registers noted inFigure 67.

The free-running FLL clock may be used to support analogue functions, for which the digital audio interface is not used, and there is no applicable Sample Rate (fs). When SYSCLK is required for circuits such the Class D, DC Servo or Charge Pump, then valid Sample Rate register settings are still required, even though the digital audio interface is not active.

For correct functionality when SYSCLK_SRC = 0, valid settings are required for AIF1_SR and AIF1CLK_RATE. In the case where SYSCLK_SRC = 1, then valid settings are required for AIF2_SR and AIF2CLK_RATE.

The control registers applicable to FLL free-running modes are described in Table 117.

Table 117 FLL Free-Running Mode

GPIO OUTPUTS FROM FLL

For each FLL, the WM1811A has an internal signal which indicates whether the FLL Lock has been achieved. The FLL Lock status is an input to the Interrupt control circuit and can be used to trigger an Interrupt event - see "Interrupts".

The FLL Lock signal can be output directly on a GPIO pin as an external indication of FLL Lock. See "General Purpose Input/Output" for details of how to configure a GPIO pin to output the FLL Lock signal.

The FLL Clock can be output directly on a GPIO pin as a clock signal for other circuits. Note that the FLL Clock may be output even if the FLL is not selected as the WM1811A SYSCLK source. The FLL clocking configuration is illustrated in Figure 70. See "General Purpose Input/Output" for details of how to configure a GPIO pin to output the FLL Clock.

EXAMPLE FLL CALCULATION

The following example illustrates how to derive the FLL1 registers to generate 12.288 MHz output (F_{OUT}) from a 12.000 MHz reference clock (F_{REF}):

- Set FLL1_REFCLK_DIV in order to generate F_{REF}<=13.5MHz: FLL1_REFCLK_DIV = 00 (divide by 1)
- Set FLL1_OUTDIV for the required output frequency as shown in Table 113:-F_{OUT} = 12.288 MHz, therefore FLL1_OUTDIV = 7h (divide by 8)
- Set FLL1_FRATIO for the given reference frequency as shown in Table 114: F_{REF} = 12MHz, therefore FLL1_FRATIO = 0h (divide by 1)
- Calculate F_{vco} as given by F_{vco} = F_{out} x FLL1_OUTDIV:- F_{vco} = 12.288 x 8 = 98.304MHz
- Calculate N.K as given by N.K = F_{VCO} / (FLL1_FRATIO x F_{REF}): N.K = 98.304 / (1 x 12) = 8.192
- Set FLL1_EFS_ENA according to whether N.K is an integer. N.K has a fractional part, therefore FLL1_EFS_ENA = 1
- Determine FLL1_N from the integer portion of N.K:-FLL_N =8.
- Determine GCD(FLL), as given by GCD(FLL) = GCD(FLL1_FRATIO x F_{REF}, F_{VCO}): GCD(FLL)= GCD(1 x 1200000, 98304000) = 96000
- Determine FLL1_THETA, as given by FLL1_THETA = (F_{VCO} - (FLL1_N x FLL1_FRATIO x F_{REF})) / GCD(FLL): FLL1_THETA = (98304000 - (8 x 1 x 12000000)) / 96000 FLL1_THETA = 24 (0018h)
- Determine FLL_LAMBDA, as given by FLL1_LAMBDA = (FLL1_FRATIO x F_{REF}) / GCD(FLL): FLL1_LAMBDA = (1 x 12000000) / 96000 FLL1_LAMBDA = 125 (007Dh)

EXAMPLE FLL SETTINGS

Table 118 provides example FLL settings for generating common SYSCLK frequencies from a variety of low and high frequency reference inputs.

| F _{SOURCE} | F _{OUT} (MHz) | F _{REF} Divider | N.K | FRATIO | F _{vco} (MHz) | OUTDIV | FLLn_N | FLLn_ EFS_EN A | FLLn_ THETA | FLLn_ LAMBDA |

 F_{OUT} = (F_{SOURCE} / F_{REF} Divider) * N.K * FRATIO / OUTDIV

The values of N and K are contained in the FLLn_N, FLLn_THETA and FLLn_LAMBDA registers as shown above.

See Table 115 and Table 116 for the coding of the FLLn_REFCLK_DIV, FLLn_FRATIO and FLLn_OUTDIV registers.

Table 118 Example FLL Settings

SAMPLE RATE CONVERSION

The WM1811A supports two main digital audio interfaces, AIF1 and AIF2. These interfaces are configured independently and may operate entirely asynchronously to each other. The WM1811A performs stereo full-duplex sample rate conversion between the audio interfaces, allowing digital audio to be routed between the interfaces, and allowing asynchronous audio data to be mixed together.

The Sample Rate Converters (SRCs) are configured automatically within the WM1811A, and no user settings are required. The SRCs are enabled automatically when required and are disabled at other times. Synchronisation between the audio interfaces is not instantaneous when the clocking or sample rate configurations are updated; the lock status of the SRCs is signalled via the GPIO or Interrupt circuits, as described in "General Purpose Input/Output" and "Interrupts".

Separate clocks can be used for AIF1 and AIF2, allowing asynchronous operation on these interfaces. The digital mixing core is clocked by SYSCLK, which is linked to either AIF1CLK or AIF2CLK, as described in "Clocking and Sample Rates". The digital mixing core is, therefore, always synchronised to AIF1, or to AIF2, or to both interfaces at once.

SAMPLE RATE CONVERTER 1 (SRC1)

SRC1 performs sample rate conversion of digital audio data input to the WM1811A. Sample Rate Conversion is required when digital audio data is received on an audio interface that is not synchronised to the digital mixing core.

SRC1 is automatically configured on AIF1 or AIF2, depending on the selected Clocking and Sample Rate configuration. Note that SRC1 cannot convert input data on AIF1 and AIF2 simultaneously.

The SRC1 Lock status indicates when audio data can be received on the interface channel that is not synchronised to the digital mixing core. No audio will be present on this signal path until SRC1 Lock is achieved.

SAMPLE RATE CONVERTER 2 (SRC2)

SRC2 performs sample rate conversion of digital audio data output from the WM1811A. Sample Rate Conversion is required when digital audio data is transmitted on an audio interface that is not synchronised to the digital mixing core.

SRC2 is automatically configured on AIF1 or AIF2, depending on the selected Clocking and Sample Rate configuration. Note that SRC2 cannot convert output data on AIF1 and AIF2 simultaneously.

The SRC2 Lock status indicates when audio data can be transmitted on the interface channel that is not synchronised to the digital mixing core. No audio will be present on this signal path until SRC2 Lock is achieved.

SAMPLE RATE CONVERTER RESTRICTIONS

The following restrictions apply to the configuration of the WM1811A Sample Rate Converters.

No SRC capability when using 88.2kHz or 96kHz AIF input (DAC playback). If either interface is configured for 88.2kHz or 96kHz sample rate, then the digital mixing core must also be configured for this sample rate. Sample Rate Conversion cannot be supported in this mode, therefore AIF output is not supported at any sample rate under these conditions.

Restricted Sample Rate options when AIF1 and AIF2 are not synchronised. When a different clock source is used for AIF1CLK and AIF2CLK, then the AIF to which the SYSCLK is synchronised cannot be mixed sample rates.

- If AIF1CLK_SRC ≠ AIF2CLK_SRC
- And SYSCLK_SRC =0
- Then AIF1DAC_DIV and AIF1ADC_DIV must be set to 000

SAMPLE RATE CONVERTER CONFIGURATION ERROR INDICATION

The WM1811A verifies the register settings relating to Clocking, Sample Rates and Sample Rate Conversion. If an invalid configuration is attempted, then the SR_ERROR register will indicate the error by showing a non-zero value. This read-only field may be checked to confirm that the WM1811A can support the selected Clocking and Sample Rate settings.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|----------|---------|--|
| R530 (0212h) | 3:0 | SR_ERROR | 0000 | Sample Rate Configuration status |
| Rate Status | | [3:0] | | Indicates an error with the register settings related to sample rate configuration |
| | | | | 0000 = No errors |
| | | | | 0001 = Invalid sample rate |
| | | | | 0010 = Invalid AIF divide |
| | | | | 0011 = ADC and DAC divides both set in an interface |
| | | | | 0100 = Invalid combination of AIF divides and sample-rate |
| | | | | 0101 = Invalid set of enables for 96kHz mode |
| | | | | 0110 = Invalid SYSCLK rate (derived from AIF1CLK_RATE or AIF2CLK_RATE) |
| | | | | 0111 = Mixed ADC and DAC rates in SYSCLK AIF when AIFs are asynchronous |
| | | | | 1000 = Invalid combination of sample rates when both AIFs are from the same clock source |
| | | | | 1001 = Invalid combination of mixed ADC/DAC AIFs when both from the same clock source |

Table 119 Sample Rate Converter Configuration Status

CONTROL INTERFACE

The WM1811A is controlled by writing to registers through a 2-wire serial control interface. Readback is available for all registers, including Chip ID and power management status.

Note that the Control Interface function can be supported with or without system clocking. Where possible, the register map access is synchronised with SYSCLK in order to ensure predictable operation of cross-domain functions. See "Clocking and Sample Rates" for further details of Control Interface clocking.

The WM1811A is a slave device on the control interface; SCLK is a clock input, while SDAT is a bidirectional data pin. To allow arbitration of multiple slaves (and/or multiple masters) on the same interface, the WM1811A transmits logic 1 by tri-stating the SDAT pin, rather than pulling it high. An external pull-up resistor is required to pull the SDAT line high so that the logic 1 can be recognised by the master.

In order to allow many devices to share a single 2-wire control bus, every device on the bus has a unique 8-bit device ID (this is not the same as the address of each register in the WM1811A). The device ID is selectable on the WM1811A, using the ADDR pin as shown in Table 120. The LSB of the Device ID is the Read/Write bit; this bit is set to logic 1 for "Read" and logic 0 for "Write".

An internal pull-down resistor is enabled by default on the ADDR pin; this can be configured using the ADDR_PD register bit described in Table 122.

| ADDR | DEVICE ID |
|------|-----------------|
| Low | 0011 0100 (34h) |
| High | 0011 0110 (36h) |

Table 120 Control Interface Device ID Selection

The WM1811A operates as a slave device only. The controller indicates the start of data transfer with a high to low transition on SDAT while SCLK remains high. This indicates that a device ID, register address and data will follow. The WM1811A responds to the start condition and shifts in the next eight bits on SDAT (8-bit device ID, including Read/Write bit, MSB first). If the device ID received matches the device ID of the WM1811A, then the WM1811A responds by pulling SDAT low on the next clock pulse (ACK). If the device ID is not recognised or the R/W bit is set incorrectly, the WM1811A returns to the idle condition and waits for a new start condition and valid address.

If the device ID matches the device ID of the WM1811A, the data transfer continues as described below. The controller indicates the end of data transfer with a low to high transition on SDAT while SCLK remains high. After receiving a complete address and data sequence the WM1811A returns to the idle state and waits for another start condition. If a start or stop condition is detected out of sequence at any point during data transfer (i.e. SDAT changes while SCLK is high), the device returns to the idle condition.

The WM1811A supports the following read and write operations:

- Single write
- Single read
- Multiple write using auto-increment
- Multiple read using auto-increment

The sequence of signals associated with a single register write operation is illustrated in Figure 72.

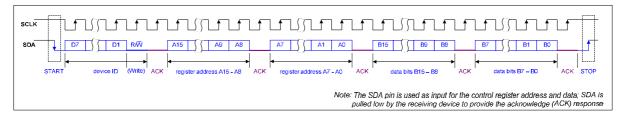

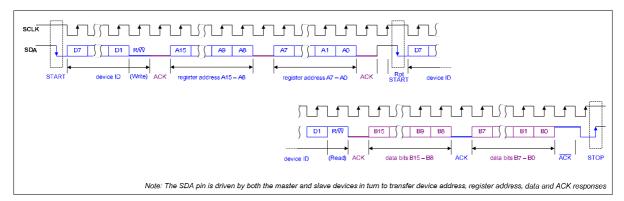

Figure 72 Control Interface 2-wire (I2C) Register Write

The sequence of signals associated with a single register read operation is illustrated in Figure 73.

Figure 73 Control Interface 2-wire (I2C) Register Read

The Control Interface also supports other register operations, as listed above. The interface protocol for these operations is summarised below. The terminology used in the following figures is detailed in Table 121.

Note that, for multiple write and multiple read operations, the auto-increment option must be enabled. This feature is enabled by default, as noted inTable 122.

| TERMINOLOGY | DESCRIPTION | | | |
|---------------|--------------------------------------|--------------------|--|--|

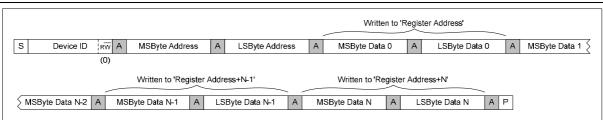

Figure 76 Multiple Register Write to Specified Address using Auto-increment

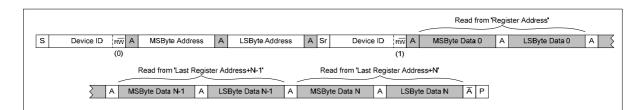

Figure 77 Multiple Register Read from Specified Address using Auto-increment

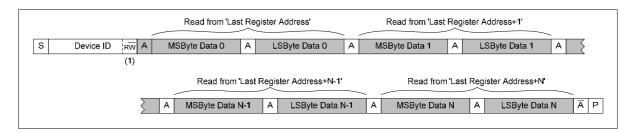

Figure 78 Multiple Register Read from Last Address using Auto-increment

Multiple Write and Multiple Read operations enable the host processor to access sequential blocks of the data in the WM1811A register map faster than is possible with single register operations. The auto-increment option is enabled when the AUTO_INC register bit is set. This bit is defined in Table 122. Auto-increment is enabled by default.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |

| | | | | 1 = Enabled |

Table 122 Control Interface Configuration

POP SUPPRESSION CONTROL

The WM1811A incorporates a number of features, including Wolfson's SilentSwitch[™] technology, designed to suppress pops normally associated with Start-Up, Shut-Down or signal path control. Note that, to achieve maximum benefit from these features, careful attention is required to the sequence and timing of these controls.

The Pop Suppression controls relating to the Headphone / Line Output drivers are described in the "Analogue Output Signal Path" section.

Additional bias controls are described in the "Reference Voltages and Master Bias" section.

DISABLED LINE OUTPUT CONTROL

The line outputs are biased to VMID in normal operation. To avoid audible pops caused by a disabled signal path dropping to AGND, the WM1811A can maintain these connections at VMID when the relevant output stage is disabled. This is achieved by connecting a buffered VMID reference to the output.

The buffered VMID reference is enabled by setting VMID_BUF_ENA. The output resistance is selectable, using the VROI register bit.

Note that, if LINEOUTn_DISCH=1 (see Table 124), then the respective output will be discharged to AGND, and will not be connected to VMID.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|--------------------------------------|-----|------------------|---------|--|
| R55 (0037h) Additional Control | 0 | VROI | 0 | Buffered VMID to Analogue Line Output Resistance (Disabled Outputs) $0 = 20k\Omega$ from buffered VMID to output $1 = 500\Omega$ from buffered VMID to output |
| R57 (0039h) AntiPOP (2) | 3 | VMID_BUF _ENA | 0 | VMID Buffer Enable 0 = Disabled 1 = Enabled (provided VMID_SEL > 00) |

Table 123 Disabled Line Output Control

LINE OUTPUT DISCHARGE CONTROL

The line output paths can be actively discharged to AGND through internal resistors if desired. This is desirable at start-up in order to achieve a known output stage condition prior to enabling the soft-start VMID reference voltage. This is also desirable in shut-down to prevent the external connections from being affected by the internal circuits.

The line outputs LINEOUT1P and LINEOUT1N are discharged to AGND by setting LINEOUT1_DISCH. The line outputs LINEOUT2P and LINEOUT2N are discharged to AGND by setting LINEOUT2_DISCH.

The discharge resistance is dependent upon the respective LINEOUTn_ENA bit, and also according to the VROI bit (see Table 123). The discharge resistance is noted in the "Electrical Characteristics" section.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|----------------------------|-----|--------------------|---------|--|
| R56 (0038h) AntiPOP (1) | 5 | LINEOUT1_DISC H | 0 | Discharges LINEOUT1P and LINEOUT1N outputs 0 = Not active 1 = Actively discharging LINEOUT1P and LINEOUT1N |
| | 4 | LINEOUT2_DISC H | 0 | Discharges LINEOUT2P and LINEOUT2N outputs 0 = Not active 1 = Actively discharging LINEOUT2P and LINEOUT2N |

Table 124 Line Output Discharge Control

VMID REFERENCE DISCHARGE CONTROL

The VMID reference can be actively discharged to AGND through internal resistors. This is desirable at start-up in order to achieve a known initial condition prior to enabling the soft-start VMID reference; this ensures maximum suppression of audible pops associated with start-up. VMID is discharged by setting VMID_DISCH.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|------------|---------|-------------------------|
| R57 (0039h) | 0 | VMID_DISCH | 0 | Connects VMID to ground |
| AntiPOP (2) | | | | 0 = Disabled |
| | | | | 1 = Enabled |

Table 125 VMID Reference Discharge Control

INPUT VMID CLAMPS

The analogue inputs can be clamped to Vmid using the INPUTS_CLAMP bit described below. This allows pre-charging of the input AC coupling capacitors during power-up. Note that all eight inputs are clamped using the same control bit.

Note that INPUTS_CLAMP must be set to 0 when the analogue input signal paths are in use.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|--------------|---------|------------------------|
| R21 (15h) | 6 | INPUTS_CLAMP | 0 | Input pad VMID clamp |
| Input Mixer (1) | | | | 0 = Clamp de-activated |
| | | | | 1 = Clamp activated |

Table 126 Input VMID Clamps

LDO REGULATORS

The WM1811A provides two integrated Low Drop-Out Regulators (LDOs). These are provided to generate the appropriate power supplies for internal circuits, simplifying and reducing the requirements for external supplies and associated components. A reference circuit powered by AVDD2 ensures the accuracy of the LDO regulator voltage settings.

Note that the integrated LDOs are only intended for generating the AVDD1 and DCVDD supply rails for the WM1811A; they are not suitable for powering any additional or external loads.

LDO1 is intended for generating AVDD1 - the primary analogue power domain of the WM1811A. LDO1 is powered by LDO1VDD and is enabled when a logic '1' is applied to the LDO1ENA pin. The logic level is determined with respect to the DBVDD1 voltage domain. The LDO1 start-up time is dependent on the external AVDD1 and VREFC capacitors; the start-up time is noted in the "Electrical Characteristics" section for the recommended external component conditions.

When LDO1 is enabled, the output voltage is controlled by the LDO1_VSEL register field. Note that the LDO1 voltage difference LDO1VDD - AVDD1 must be higher than the LDO1 Drop-Out voltage (see "Electrical Characteristics").

When LDO1 is disabled(by applying a logic '0' to the LDO1ENA pin), the output can be left floating or can be actively discharged, depending on the LDO1_DISCH control bit.

It is possible to supply AVDD1 from an external supply. If AVDD1 is supplied externally, then LDO1 should be disabled, and the LDO1 output left floating (LDO1DISCH = 0). Note that the LDO1VDD voltage must be greater than or equal to AVDD1; this ensures that there is no leakage path through the LDO for the external supply.

Note that the WM1811A can operate with AVDD1 tied to 0V; power consumption may be reduced, but the analogue audio functions will not be supported.

LDO2 is intended for generating the DCVDD power domain which supplies the digital core functions on the WM1811A. LDO2 is powered by DBVDD1 and is enabled when a logic '1' is applied to the LDO2ENA pin. The logic level is determined with respect to the DBVDD1 voltage domain. The LDO2 start-up time is dependent on the external DCVDD and VREFC capacitors; the start-up time is noted in the "Electrical Characteristics" section for the recommended external component conditions.

When LDO2 is enabled, the output voltage is controlled by the LDO2_VSEL register field.

When LDO2 is disabled (by applying a logic '0' to the LDO2ENA pin), the output can be left floating or can be actively discharged, depending on the LDO2_DISCH control bit.

It is possible to supply DCVDD from an external supply. If DCVDD is supplied externally, the LDO2ENA and LDO2DISCH bits should be set to 0. Note that the DBVDD1 voltage must be greater than or equal to DCVDD; this ensures that there is no leakage path through the LDO for the external supply.

An internal pull-down resistor is enabled by default on the LDO1ENA and LDO2ENA pins. These pulldown resistors can be configured using the register bits described in Table 127.

Decoupling capacitors should be connected to the voltage reference pin, VREFC, and also to the LDO outputs, AVDD1 and DCVDD. See "Applications Information" for further details.

The LDO Regulator connections and controls are illustrated in Figure 79. The register controls are defined in Table 127.

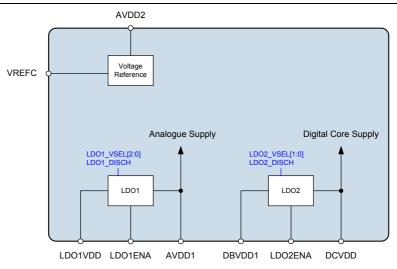

Figure 79 LDO Regulators

Table 127 LDO Regulator Control

REFERENCE VOLTAGES AND MASTER BIAS

This section describes the analogue reference voltage and bias current controls. It also describes the VMID soft-start circuit for pop suppressed start-up and shut-down.

The analogue circuits in the WM1811A require a mid-rail analogue reference voltage, VMID. This reference is generated from AVDD1 via a programmable resistor chain. Together with the external VMID decoupling capacitor, the programmable resistor chain determines the charging characteristic on VMID. This is controlled by VMID_SEL[1:0], and can be used to optimise the reference for normal operation or low power standby as described in Table 128.

A buffered mid-rail reference voltage is provided. This is required for the single-ended configuration of the Input PGAs, and also for direct signal paths from the input pins to the Input Mixers, Output Mixers or Speaker Mixers. These requirements are noted in the relevant "Analogue Input Signal Path" and "Analogue Output Signal Path" sections. The buffered mid-rail reference is enabled by setting the VMID_BUF_ENA register bit.

The analogue circuits in the WM1811A require a bias current. The normal bias current is enabled by setting BIAS_ENA. Note that the normal bias current source requires VMID to be enabled also.

| REGISTER ADDRESS | BIT | LABEL | DEFAUL T | DESCRIPTION |
|--|-----|-------------------|-------------|---|
| R1 (0001h) Power Management (1) | 2:1 | VMID_SEL [1:0] | 00 | VMID Divider Enable and Select 00 = VMID disabled (for OFF mode) $01 = 2 \times 40 k\Omega$ divider (for normal operation) $10 = 2 \times 240 k\Omega$ divider (for low power standby) |
| | | | | 11 = Reserved |
| | 0 | BIAS_ENA | 0 | Enables the Normal bias current generator (for all analogue functions) |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |
| R57 (0039h) | 3 | VMID_BUF_ | 0 | VMID Buffer Enable |
| AntiPOP (2) | | ENA | | 0 = Disabled |
| | | | | 1 = Enabled (provided VMID_SEL > 00) |

Table 128 Reference Voltages and Master Bias Enable

A pop-suppressed start-up requires VMID to be enabled smoothly, without the step change normally associated with the initial stage of the VMID capacitor charging. A pop-suppressed start-up also requires the analogue bias current to be enabled throughout the signal path prior to the VMID reference voltage being applied. The WM1811A incorporates pop-suppression circuits which address these requirements.

An alternate bias current source (Start-Up Bias) is provided for pop-free start-up; this is enabled by the STARTUP_BIAS_ENA register bit. The start-up bias is selected (in place of the normal bias) using the BIAS_SRC bit. It is recommended that the start-up bias is used during start-up, before switching back to the higher quality, normal bias.

A soft-start circuit is provided in order to control the switch-on of the VMID reference. The soft-start control circuit offers two slew rates for enabling the VMID reference; these are selected and enabled by VMID_RAMP. When the soft-start circuit is enabled prior to enabling VMID_SEL, the reference voltage rises smoothly, without the step change that would otherwise occur. It is recommended that the soft-start circuit and the output signal path be enabled before VMID is enabled by VMID_SEL.

A soft shut-down is provided, using the soft-start control circuit and the start-up bias current generator. The soft shut-down of VMID is achieved by setting VMID_RAMP, STARTUP_BIAS_ENA and BIAS_SRC to select the start-up bias current and soft-start circuit prior to setting VMID_SEL=00.

Note that, if the VMID_RAMP function is enabled for soft start-up or soft shut-down then, after setting VMID_SEL = 00 to disable VMID, the soft-start circuit must be reset before re-enabling VMID. The soft-start circuit is reset by setting VMID_RAMP = 00. After resetting the soft-start circuit, the VMID_RAMP register may be updated to the required setting for the next VMID transition.

The VMID soft-start register controls are defined in Table 129.

Production Data

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|----------------------------|-----|----------------------|---------|--|
| R57 (0039h) AntiPOP (2) | 6:5 | VMID_RAMP [1:0] | 10 | VMID soft start enable / slew rate control |

| | | | | 0 = Normal bias |
| | | | | 1 = Start-Up bias |

Table 129 Soft Start Control

POWER MANAGEMENT

The WM1811A has control registers that allow users to select which functions are active. For minimum power consumption, unused functions should be disabled. To minimise pop or click noise, it is important to enable or disable functions in the correct order. See "Analogue Output Signal Path" for details of recommended output driver control sequences.

| | | | | the FLL2 enable sequence, ie. after the other FLL registers have been |
| | | | | configured. |

Table 130 Power Management

THERMAL SHUTDOWN

The WM1811A incorporates a temperature sensor which detects when the device temperature is within normal limits or if the device is approaching a hazardous temperature condition. The temperature sensor can be configured to automatically disable the audio outputs of the WM1811A in response to an overtemperature condition (approximately 150°C).

The temperature status can be output directly on a GPIO pin, as described in the "General Purpose Input/Output" section. The temperature sensor can also be used to generate Interrupt events, as described in the "Interrupts" section. The GPIO and Interrupt functions can be used to indicate either a Warning Temperature event or the Shutdown Temperature event.

The temperature sensor is enabled by setting the TSHUT_ENA register bit. When the TSHUT_OPDIS is also set, then a device over-temperature condition will cause the speaker outputs (SPKOUTL and SPKOUTR) of the WM1811A to be disabled; this response is likely to prevent any damage to the device attributable to the large currents of the output drivers.

Note that, to prevent pops and clicks, TSHUT_ENA and TSHUT_OPDIS should only be updated whilst the speaker and headphone outputs are disabled.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|---------------------|-----|-------------|---------|---|

| | | | | if an overtemperature occurs. The thermal sensor must also be enabled.) |
| | | | | , |
| | | | | 0 = Disabled |
| | | | | 1 = Enabled |

Table 131 Thermal Shutdown

The WM1811A includes a Power-On Reset (POR) circuit, which issued to reset the digital logic into a default state after power up. The POR circuit derives its output from AVDD2 and DCVDD. The internal POR signal is asserted low when AVDD2 and DCVDD are below minimum thresholds.

The specific behaviour of the circuit will vary, depending on relative timing of the supply voltages. Typical scenarios are illustrated in Figure 80 and Figure 81.

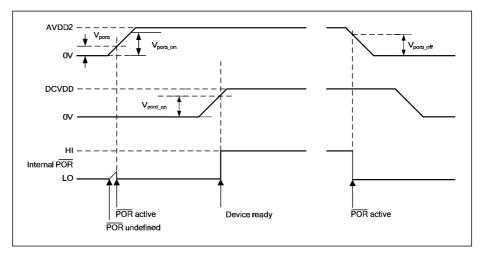

Figure 80 Power On Reset Timing – AVDD2 enabled/disabled first

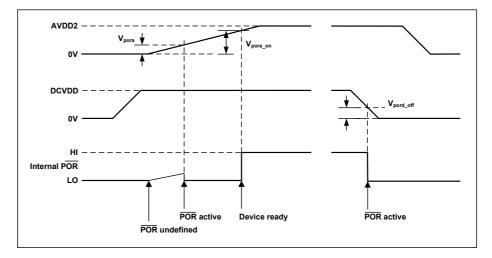

Figure 81 Power On Reset Timing - DCVDD enabled/disabled first

The \overrightarrow{POR} signal is undefined until AVDD2 has exceeded the minimum threshold, V_{pora} . Once this threshold has been exceeded, \overrightarrow{POR} is asserted low and the chip is held in reset. In this condition, all writes to the control interface are ignored. Once AVDD2 and DCVDD have reached their respective power on thresholds, \overrightarrow{POR} is released high, all registers are in their default state, and writes to the control interface may take place.

Note that a power-on reset period, T_{POR} , applies afterAVDD2 and DCVDD have reached their respective power on thresholds. This specification is guaranteed by design rather than test.

On power down, POR is asserted low when either AVDD2 or DCVDD falls below their respective power-down thresholds.

| SYMBOL | DESCRIPTION | TYP | UNIT |
|-----------------------|-------------------------------|------|------|
| V _{pora_on} | Power-On threshold (AVDD2) | 1.15 | V |
| V _{pora_off} | Power-Off threshold (AVDD2) | 1.14 | V |
| V _{pord_on} | Power-On threshold (DCVDD) | 0.56 | V |
| V _{pord_off} | Power-Off threshold (DCVDD) | 0.55 | V |
| T _{POR} | Minimum Power-On Reset period | 100 | ns |

Typical Power-On Reset parameters for the WM1811A are defined in Table 132.

Table 132 Typical Power-On Reset Parameters

Table 133 describes the status of the WM1811A digital I/O pins when the Power On Reset has completed, prior to any register writes. The same conditions apply on completion of a Software Reset (described in the "Software Reset and Device ID" section).

Table 133 WM1811A Digital I/O Status in Reset

Note that the dual function IN2LN/DMICDAT pin defaults to IN2LN (analogue input) after Power On Reset is completed. The IN2LN function is referenced to the AVDD1 power domain.

SOFTWARE RESET AND DEVICE ID

The device ID can be read back from register R0. Writing to this register will reset the device.

The software reset causes all control registers to be reset to their default state.

The status of the WM1811A digital I/O pins following a software reset is described in Table 133.

The Customer ID and Device Revision can be read back from register R256.

| REGISTER ADDRESS | BIT | LABEL | DEFAULT | DESCRIPTION |
|-----------------------------|------|--------------------|---------|---|
| R0 (0000h) Software | 15:0 | SW_RESET [15:0] | 1811h | Writing to this register resets all registers to their default state. |
| Reset | | | | Reading from this register will indicate device ID 1811h. |
| R256 | 15:8 | CUST_ID [7:0] | | Customer ID |
| (0100h) Chip Revision | 3:0 | CHIP_REV [3:0] | | Chip revision |

APPLICATIONS INFORMATION

RECOMMENDED EXTERNAL COMPONENTS

AUDIO INPUT PATHS

The WM1811A provides 8 analogue audio inputs. Each of these inputs is referenced to the internal DC reference, VMID. A DC blocking capacitor is required for each input pin used in the target application. The choice of capacitor is determined by the filter that is formed between that capacitor and the input impedance of the input pin. The circuit is illustrated in Figure 82.

If the input impedance is known, and the cut-off frequency is known, then the minimum capacitor value may be derived easily. However, it can be seen from the representation in Figure 82 that the input impedance is not fixed in all applications but can vary with gain and boost amplifier settings.

| IN1L_VOL[4:0], IN2L_VOL[4:0], | VOLUME (dB) | - | SISTANCE Ω) |

| 11110 | +28.5 | 2.9 | 1.5 | |
| 11111 | +30.0 | 2.5 | 1.3 | |

Table 135 PGA Input Pin Resistance

The appropriate input capacitor may be selected using the PGA input resistance data provided in Table 135, depending on the required PGA gain setting(s).

The choice of capacitor for a 20Hz cut-off frequency is shown in Table 136 for a selection of typical input impedance conditions.

| INPUT IMPEDANCE | MINIMUM CAPACITANCE FOR 20HZ PASS BAND |
|-----------------|---|
| 2kΩ | 4 μF |
| 15kΩ | 0.5 μF |
| 30kΩ | 0.27 μF |
| 60kΩ | 0.13 μF |

Table 136 Audio InputDC Blocking Capacitors

Using the figures in Table 136, it follows that a 1μ F capacitance for all input connections will give good results in most cases. Tantalum electrolytic capacitors are particularly suitable as they offer high stability in a small package size.

Ceramic equivalents are a cost effective alternative to the superior tantalum packages, but care must be taken to ensure the desired capacitance is maintained at the AVDD1 operating voltage. Also, ceramic capacitors may show microphonic effects, where vibrations and mechanical conditions give rise to electrical signals. This is particularly problematic for microphone input paths where a large signal gain is required.

A single capacitor is required for a line input or single-ended microphone connection. In the case of a differential microphone connection, a DC blocking capacitor is required on both input pins.

HEADPHONE OUTPUT PATH

The headphone output on WM1811A is ground referenced and therefore does not require the large, expensive capacitors necessary for VMID reference solutions. The headphone load may be connected directly to the HPOUT1L and HPOUT1R pins, as illustrated in the "Analogue Outputs" section.

EARPIECE DRIVER OUTPUT PATH

The earpiece driver on HPOUT2P and HPOUT2Nis designed as a 32ohm BTL speaker driver. The outputs are referenced to the internal DC reference VMID, but direct connection to the speaker is possible because of the BTL configuration. There is no requirement for DC blocking capacitors.

LINE OUTPUT PATHS

The WM1811A provides four line outputs (LINEOUT1P, LINEOUT1N, LINEOUT2P and LINEOUT2N). Each of these outputs is referenced to the internal DC reference, VMID. In any case where a line output is used in a single-ended configuration (i.e. referenced to AGND), a DC blocking capacitor will be required in order to remove the DC bias. In the case where a pair of line outputs is configured as a BTL differential pair, then the DC blocking capacitor should be omitted.

The choice of capacitor is determined from the filter that is formed between the capacitor and the load impedance – see Figure 83.

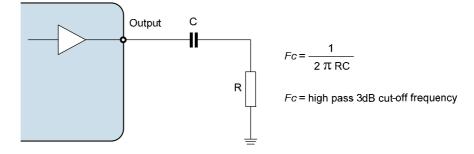

Figure 83 Line Output Path Components

| LOAD IMPEDANCE | MINIMUM CAPACITANCE FOR 20HZ PASS BAND |
|----------------|---|
| 10kΩ | 0.8 μF |
| 47 kΩ | 0.17 μF |

Table 137 Line Output Frequency Cut-Off

Using the figures in Table 137, it follows that that a 1μ F capacitance would be a suitable choice for a line load. Tantalum electrolytic capacitors are again particularly suitable but ceramic equivalents are a cost effective alternative. Care must be taken to ensure the desired capacitance is maintained at the appropriate operating voltage.

POWER SUPPLY DECOUPLING

Electrical coupling exists particularly in digital logic systems where switching in one sub-system causes fluctuations on the power supply. This effect occurs because the inductance of the power supply acts in opposition to the changes in current flow that are caused by the logic switching. The resultant variations (or 'spikes') in the power supply voltage can cause malfunctions and unintentional behavior in other components. A decoupling (or 'bypass') capacitor can be used as an energy storage component which will provide power to the decoupled circuit for the duration of these power supply variations, protecting it from malfunctions that could otherwise arise.

Coupling also occurs in a lower frequency form when ripple is present on the power supply rail caused by changes in the load current or by limitations of the power supply regulation method. In audio components such as the WM1811A, these variations can alter the performance of the signal path, leading to degradation in signal quality. A decoupling (or 'bypass') capacitor can be used to filter these effects, by presenting the ripple voltage with a low impedance path that does not affect the circuit to be decoupled.

These coupling effects are addressed by placing a capacitor between the supply rail and the corresponding ground reference. In the case of systems comprising multiple power supply rails, decoupling should be provided on each rail.

| POWER SUPPLY | DECOUPLING CAPACITOR | | |
|---|-------------------------|--|--|
| LDO1VDD, DBVDD1, DBVDD2, DBVDD3, AVDD2 | 0.1µF ceramic(see Note) | | |
| SPKVDD1, SPKVDD2 | 4.7µF ceramic | | |
| AVDD1 | 4.7µF ceramic | | |
| DCVDD | 1.0μF ceramic | | |
| CPVDD | 4.7µF ceramic | | |
| VMIDC | 4.7µF ceramic | | |
| VREFC | 1.0µF ceramic | | |

The recommended power supply decoupling capacitors for WM1811A are listed below in Table 138.

Table 138 Power Supply Decoupling Capacitors

Note: 0.1μ F is required with 4.7μ F a guide to the total required power rail capacitance, including that at the regulator output.

All decoupling capacitors should be placed as close as possible to the WM1811A device. The connection between AGND, the AVDD1 decoupling capacitor and the main system ground should be made at a single point as close as possible to the AGND ball of the WM1811A.

The VMID capacitor is not, technically, a decoupling capacitor. However, it does serve a similar purpose in filtering noise on the VMID reference. The connection between AGND, the VMID decoupling capacitor and the main system ground should be made at a single point as close as possible to the AGND ball of the WM1811A.

Due to the wide tolerance of many types of ceramic capacitors, care must be taken to ensure that the selected components provide the required capacitance across the required temperature and voltage ranges in the intended application. For most applications, the use of ceramic capacitors with capacitor dielectric X5R is recommended.

CHARGE PUMP COMPONENTS

A fly-back capacitor is required between the CPCA and CPCB pins. The required capacitance is $2.2\mu\text{F}$ at 2V.

A decoupling capacitor is required on CPVOUTP and CPVOUTN; the recommended value is $2.2\mu F$ at 2V.

The positioning of the Charge Pump capacitors is important, particularly the fly-back capacitor. These capacitors should be placed as close as possible to the WM1811A.

Due to the wide tolerance of many types of ceramic capacitors, care must be taken to ensure that the selected components provide the required capacitance across the required temperature and voltage ranges in the intended application. For most applications, the use of ceramic capacitors with capacitor dielectric X5R is recommended.

MICROPHONE BIAS CIRCUIT

The WM1811A is designed to interface easily with up to four analogue microphones. These may be connected in single-ended or differential configurations, as illustrated in Figure 84. The single-ended method allows greater capability for the connection of multiple audio sources simultaneously, whilst the differential method provides better performance due to its rejection of common-mode noise.

In either configuration, the analogue microphone requires a bias current (electret condenser microphones) or voltage supply (silicon microphones), which can be provided by MICBIAS1 or MICBIAS2.

A current-limiting resistor is required when using an electret condenser microphone (ECM). The resistance should be chosen according to the minimum operating impedance of the microphone and MICBIAS voltage so that the maximum bias current of the WM1811A is not exceeded. Wolfson recommends a $2.2k\Omega$ current limiting resistor as it provides compatibility with a wide range of microphone models.

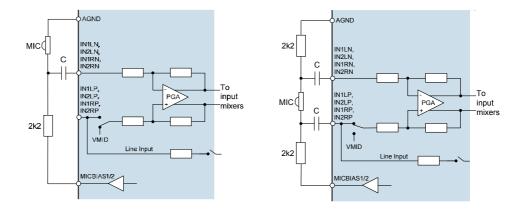

Figure 84 Single-Ended and Differential Analogue Microphone Connections

The WM1811A also supports up to two digital microphone inputs. The MICBIAS1 generator is suitable for use as a low noise supply for digital microphones, as shown in Figure 85.

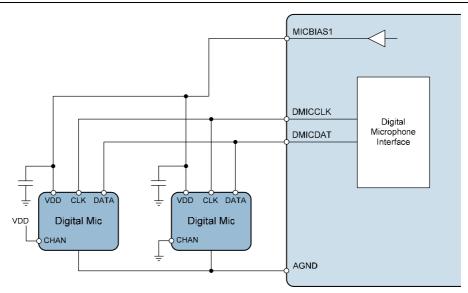

Figure 85 Digital Microphone Connection

The MICBIAS generators can each operate as a voltage regulator or in bypass mode. See "Analogue Input Signal Path" for details of the MICBIAS generators.

In Regulator mode, the MICBIAS regulators are designed to operate without external decoupling capacitors. It is important that parasitic capacitances on the MICBIAS1 or MICBIAS2 pins do not exceed the specified limit in Regulator mode (see "Electrical Characteristics").

If the capacitive load on MICBIAS1 or MICBIAS2 exceeds the specified limit (eg. due to a decoupling capacitor or long PCB trace), then the respective generator must be configured in Bypass mode.

The maximum output current is noted in the "Electrical Characteristics". This limit must be observed on each MICBIAS output, especially if more than one microphone is connected to a single MICBIAS pin. Note that the maximum output current differs between Regulator mode and Bypass mode. The MICBIAS output voltage can be adjusted using register control in Regulator mode.

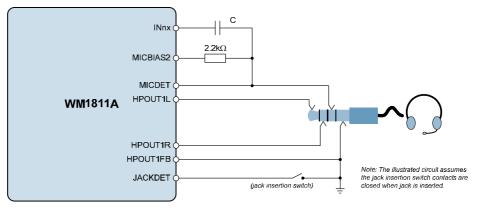

EXTERNAL ACCESSORY DETECTION COMPONENTS

The external accessory detection circuit measures jack insertion using the JACKDET pin. The insertion switch status is detected using an internal pull-up resistor circuit on the JACKDET pin.

Microphone detection and key-button press detection is supported using the MICDET pin. This pin should be connected to the MICBIAS2 output, via a $2.2k\Omega$ current-limiting resistor, as described in the "Microphone Bias Circuit" section.

A recommended circuit configuration, including headphone output on HPOUT1 and microphone connections, is shown in Figure 86. See "Audio Input Paths" for details of the DC-blocking microphone input capacitor selection.

The recommended external components and connections for microphone / push-button detection are illustrated in Figure 87.

The microphone / accessory detection circuit measures the impedance of an external load connected to the MICDET pin.

This function uses the MICBIAS2 output as a reference. Note that the WM1811A will automatically enable MICBIAS2 when required in order to perform the detection function.

The WM1811A can detect the presence of a typical microphone and up to 7 push-buttons, using the components shown in Figure 87. When the microphone detection circuit is enabled, then each of the push-buttons shown will cause a different bit within the MICD_LVL register to be set.

The microphone detect function is specifically designed to detect a video accessory (typical 75 Ω) load if required. A measured external impedance of 75 Ω will cause the MICD_LVL [4] bit to be set.

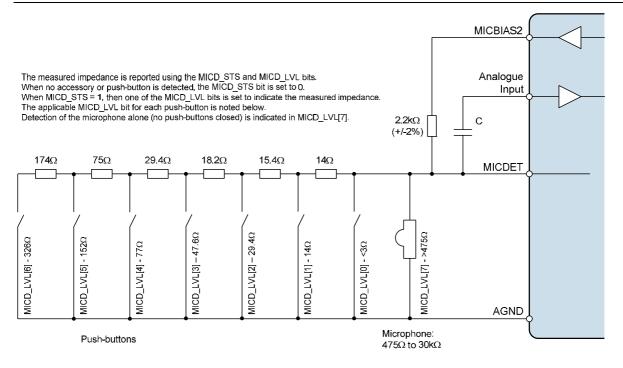

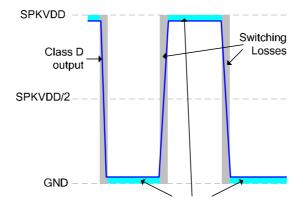

Figure 87 Microphone / Push-Button External Components

CLASS D SPEAKER CONNECTIONS

The WM1811A incorporates two Class D speaker drivers, which offer high amplifier efficiency at large signal levels. As the Class D output is a pulse width modulated signal, the choice of speakers and tracking of signals is critical for ensuring good performance and reducing EMI in this mode.

The efficiency of the speaker drivers is affected by the series resistance between the WM1811A and the speaker (e.g. PCB track loss and inductor ESR) as shown in Figure 88. This resistance should be as low as possible to maximise efficiency.

Losses due to resistance between WM1811A and speaker (e.g. inductor ESR) This resistance must be minimised in order to maximise efficiency.

Figure 88 Speaker Connection Losses

The Class D output requires external filtering in order to recreate the audio signal. This may be implemented using a 2nd order LC or 1st order RC filter, or else may be achieved by using a loudspeaker whose internal inductance provides the required filter response. An LC or RC filter should be used if the loudspeaker characteristics are unknown or unsuitable, or if the length of the loudspeaker connection is likely to lead to EMI problems.

In applications where it is necessary to provide Class D filter components, a 2nd order LC filter is the recommended solution as it provides more attenuation at higher frequencies and minimises power dissipated in the filter when compared to a first order RC filter (lower ESR). This maximises both rejection of unwanted switching frequencies and overall speaker efficiency. A suitable implementation is illustrated in Figure 89.

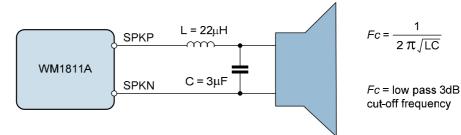

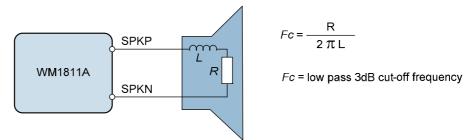

Figure 89 Class D Output Filter Components

A simple equivalent circuit of a loudspeaker consists of a serially connected resistor and inductor, as shown in Figure 90. This circuit provides a low pass filter for the speaker output. If the loudspeaker characteristics are suitable, then the loudspeaker itself can be used in place of the filter components described earlier. This is known as 'filterless' operation.

For filterless Class D operation, it is important to ensure that a speaker with suitable inductance is chosen. For example, if we know the speaker impedance is 8Ω and the desired cut-off frequency is 20kHz, then the optimum speaker inductance may be calculated as:

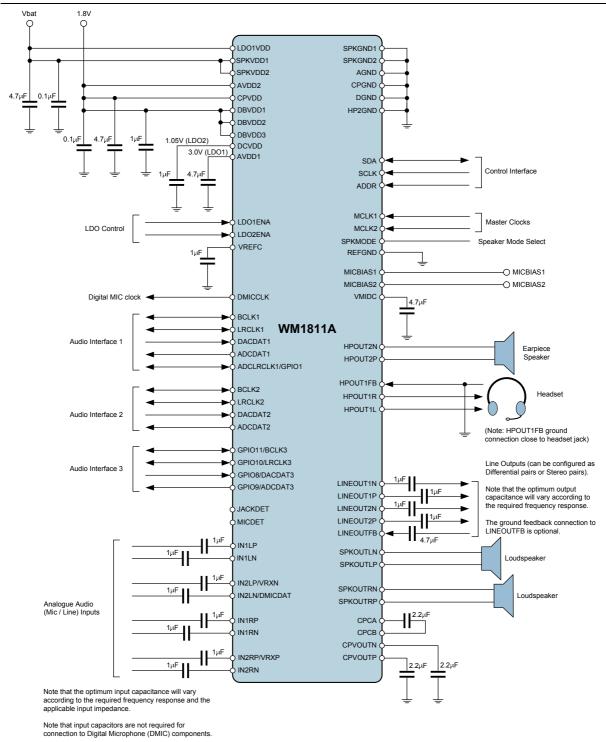

$$L = \frac{R}{2 \pi Fc} = \frac{8\Omega}{2 \pi * 20 \text{kHz}} = 64 \mu \text{H}$$

 8Ω loudspeakers typically have an inductance in the range 20μ H to 100μ H, however, it should be noted that a loudspeaker inductance will not be constant across the relevant frequencies for Class D operation (up to and beyond the Class D switching frequency). Care should be taken to ensure that the cut-off frequency of the loudspeaker's filtering is low enough to suppress the high frequency energy of the Class D switching and, in so doing, to prevent speaker damage. The Class D outputs of the WM1811A operate at much higher frequencies than is recommended for most speakers and it must be ensured that the cut-off frequency is low enough to protect the speaker.

RECOMMENDED EXTERNAL COMPONENTS DIAGRAM

Figure 91provides a summary of recommended external components for WM1811A. Note that this diagram does not include any components that are specific to the end application e.g. it doesnot include filtering on the speaker outputs (assume filterless Class D operation), RF decoupling, or RF filtering for pins which connect to the external world i.e. headphone or speaker outputs.

DIGITAL AUDIO INTERFACE CLOCKING CONFIGURATIONS

The WM1811A provides 3 digital audio interfaces and supports many different clocking configurations. The asynchronous sample rate converter enables more than one digital audio interface to be supported simultaneously, even when there is no synchronisation between these interfaces. In a typical application, this enables audio mixing between a multimedia applications processor and a baseband voice call processor, for example.

The AIF1 and AIF2 audio interfaces can be configured in Master or Slave modes, and can also support defined combinations of mixed sample rates. In all applications, it is important that the system clocking configuration is correctly designed. Incorrect clock configurations will lead to audible clicks arising from dropped or repeated audio samples; this is caused by the inherent tolerances of multiple asynchronous system clocks.

To ensure reliable clocking of the audio interface functions, it is a requirement that, for each audio interface, the external interface clocks (eg. BCLK, LRCLK) are derived from the same clock source as the respective AIF clock (AIFnCLK).

In AIF Master mode, the external BCLK and LRCLK signals are generated by the WM1811A and synchronisation of these signals with AIFnCLK is guaranteed. In this case, clocking of the AIF is derived from the MCLK1 or MCLK2 inputs, either directly or via one of the Frequency Locked Loop (FLL) circuits.

In AIF Slave mode, the external BCLK and LRCLK signals are generated by another device, as inputs to the WM1811A. In this case, it must be ensured that the respective AIF clock is generated from a source that is synchronised to the external BCLK and LRCLK inputs. In a typical Slave mode application, the BCLK input is selected as the clock reference, using the FLL to perform frequency shifting. It is also possible to use the MCLK1 or MCLK2 inputs, but only if the selected clock is synchronised externally to the BCLK and LRCLK inputs.

The valid AIF clocking configurations are listed in Table 139 for AIF Master and AIF Slave modes.

| AUDIO INTERFACE MODE | DE CLOCKING CONFIGURATION | | |
|----------------------|---|--|--|
| AIF Master Mode | AIFnCLK_SRC selects FLL1 or FLL2 as AIFnCLK source; FLLn_REFCLK_SRC selects MCLK1 or MCLK2 as FLLn source. | | |
| | AIFnCLK_SRC selects MCLK1 or MCLK2 as AIFnCLK source. | | |
| AIF Slave Mode | AIFnCLK_SRC selects FLL1 or FLL2 as AIFnCLK source; FLLn_REFCLK_SRC selects BCLKn as FLLn source. | | |
| | AIFnCLK_SRC selects MCLK1 or MCLK2 as AIFnCLK source, provided MCLK is externally synchronised to the BCLKn input. | | |
| | AIFnCLK_SRC selects FLL1 or FLL2 as AIFnCLK source; FLLn_REFCLK_SRC selects MCLK1 or MCLK2 as FLLn source, provided MCLK is externally synchronised to the BCLKn input. | | |

Table 139 Audio Interface Clocking Confgurations

In each case, the AIFnCLK frequency must be a valid ratio to the LRCLKn frequency; the supported clocking ratios are defined by the AIFnCLK_RATE register.

The valid AIF clocking configurations are illustrated in Figure 92 to Figure 96below.Note that, where MCLK1 is illustrated as the clock source, it is equally possible to select MCLK2 as the clock source. Similarly, in cases where FLL1 is illustrated, it is equally possible to select the FLL2.

PCB LAYOUT CONSIDERATIONS

Poor PCB layout will degrade the performance and be a contributory factor in EMI, ground bounce and resistive voltage losses. All external components should be placed as close to the WM1811A device as possible, with current loop areas kept as small as possible. Specific factors relating to Class D loudspeaker connection are detailed below.

CLASS D LOUDSPEAKER CONNECTION

Long, exposed PCB tracks or connection wires will emit EMI. The distance between the WM1811A and the loudspeaker should therefore be kept as short as possible. Where speakers are connected to the PCB via a cable form, it is recommended that a shielded twisted pair cable is used. The shield should be connected to the main system, with care taken to ensure ground loops are avoided.

Further reduction in EMI can be achieved using PCB ground (or VDD) planes and also by using passive LC components to filter the Class D switching waveform. When passive filtering is used, low ESR components should be chosen in order to minimise the series resistance between the WM1811A and the speaker, maximising the power efficiency.

LC passive filtering will usually be effective at reducing EMI at frequencies up to around 30MHz. To reduce emissions at higher frequencies, ferrite beads can also be used. These should be positioned as close to the device as possible.

These techniques for EMI reduction are illustrated in Figure 97.

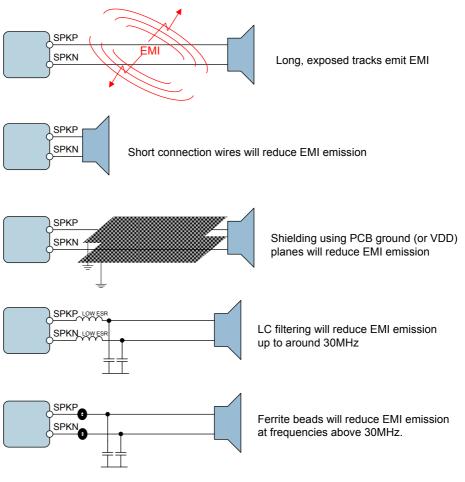

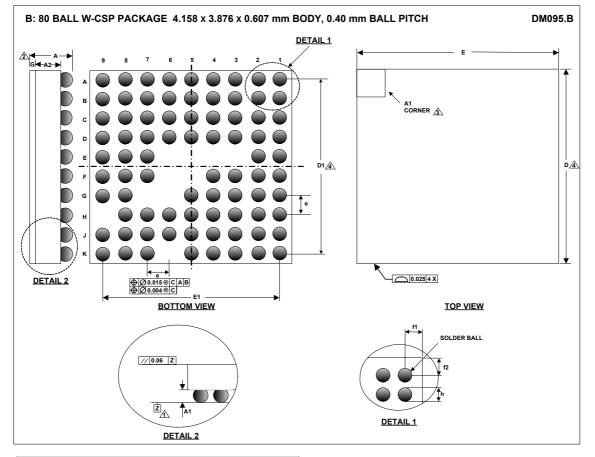

Figure 97 EMI Reduction Techniques

PACKAGE DIMENSIONS

| Symbols | Dimensions (mm) | | | | |
|---------|-----------------|-----------|-------|------|--|
| | MIN | NOM | MAX | NOTE | |
| A | 0.573 | 0.607 | 0.641 | | |
| A1 | 0.172 | 0.202 | 0.232 | | |
| A2 | 0.367 | 0.383 | 0.399 | | |
| D | 4.133 | 4.158 | 4.183 | 4 | |
| D1 | | 3.600 BSC | | | |
| E | 3.851 | 3.876 | 3.901 | 4 | |
| E1 | | 3.200 BSC | | | |
| е | | 0.400 BSC | | 5 | |
| f1 | | 0.338 BSC | | 8 | |
| f2 | | 0.279 BSC | | 9 | |
| g | | 0.022 | | | |
| h | 0.258 | 0.262 | 0.266 | | |

NOTES: 1. PRIMARY DATUM -Z- AND SEATING PLANE ARE DEFINED BY THE SPHERICAL CROWNS OF THE SOLDER BALLS. 2. THIS DIMENSION INCLUDES STAND-OFF HEIGHT 'A1', SILICON THICKNESS AND BACKSIDE COATING. 3. A1 CORNER IS IDENTIFIED BY INKILASER MARK ON TOP PACKAGE. 4. BILATERAL TOLERANCE ZONE IS APPLIED TO EACH SIDE OF THE PACKAGE BODY. 5. 'o' REPRESENTS THE BASIC SOLDER BALL GRID PITCH. 6. THIS DRAWING IS SUBJECT TO CHANGE WITHOUT NOTICE. 7. FOLLOWS JEDEC DESIGN GUIDE MO-211-C. 8. f1 = NOMINAL DISTANCE OF BALL CENTRE TO DIE EDGE X AXIS (AS PER POD) – APPLICABLE TO ALL CORNERS OF DIE. 9. (2 = NOMINAL DISTANCE OF DIE CENTRE TO DIE EDGE IN Y AXIS (AS PER POD) – APPLICABLE TO ALL CORNERS OF DIE.

Wolfson Microelectronics plc ("Wolfson") products and services are sold subject to Wolfson's terms and conditions of sale, delivery and payment supplied at the time of order acknowledgement.

Wolfson warrants performance of its products to the specifications in effect at the date of shipment. Wolfson reserves the right to make changes to its products and specifications or to discontinue any product or service without notice. Customers should therefore obtain the latest version of relevant information from Wolfson to verify that the information is current.

Testing and other quality control techniques are utilised to the extent Wolfson deems necessary to support its warranty. Specific testing of all parameters of each device is not necessarily performed unless required by law or regulation.

In order to minimise risks associated with customer applications, the customer must use adequate design and operating safeguards to minimise inherent or procedural hazards. Wolfson is not liable for applications assistance or customer product design. The customer is solely responsible for its selection and use of Wolfson products. Wolfson is not liable for such selection or use nor for use of any circuitry other than circuitry entirely embodied in a Wolfson product.

Wolfson's products are not intended for use in life support systems, appliances, nuclear systems or systems where malfunction can reasonably be expected to result in personal injury, death or severe property or environmental damage. Any use of products by the customer for such purposes is at the customer's own risk.

Wolfson does not grant any licence (express or implied) under any patent right, copyright, mask work right or other intellectual property right of Wolfson covering or relating to any combination, machine, or process in which its products or services might be or are used. Any provision or publication of any third party's products or services does not constitute Wolfson's approval, licence, warranty or endorsement thereof. Any third party trade marks contained in this document belong to the respective third party owner.

Reproduction of information from Wolfson datasheets is permissible only if reproduction is without alteration and is accompanied by all associated copyright, proprietary and other notices (including this notice) and conditions. Wolfson is not liable for any unauthorised alteration of such information or for any reliance placed thereon.

Any representations made, warranties given, and/or liabilities accepted by any person which differ from those contained in this datasheet or in Wolfson's standard terms and conditions of sale, delivery and payment are made, given and/or accepted at that person's own risk. Wolfson is not liable for any such representations, warranties or liabilities or for any reliance placed thereon by any person.

REVISION HISTORY

| DATE | REV | DESCRIPTION OF CHANGES | PAGE | CHANGED BY |
|--------------|--|--|------|------------|
| 18/111/11 | 2.0 | Initial version | | PH |
| 24/11/11 3.0 | | Maximum MICBIASn load capacitance noted in Electrical Characteristics. | | PH |
| | | Specifications added for LINEOUTFB and HPOUT1FB ground noise rejection. | | |
| | | CMRR specifications added for differential input paths. | | |
| 01/03/12 3.0 | Description of JACKDET_LVL and JACKDET_MODE updated. | | PH | |
| | | System clocking updated - DBCLK is derived independently of TOCLK_ENA. | | |
| | Package dimensions and drawing updated. | | | |
| | Additional details in Absolute Maximum Ratings. | | | |
| | | Clarification of Line Output discharge functions and associated Electrical Characteristics. | | |
| | | Additional details provided for Headphone Enable sequence. | | |
| 11/09/12 3.0 | 3.0 | PSRR values added to Electrical Characteristics. | | KOL |
| | Updated Headphone Output Enable Sequence. | | | |
| 27/06/13 | 4.0 | Final PSRR values added to Electrical Characteristics. | | PH |
| 01/11/13 | 4.1 | Corrected symbols in Figures 89 and 90. | | JMacD |
| 04/08/14 | 4.2 | Speaker Driver maximum output rating added | 17 | PH |
| | | | | |
