

# IGBT motor drives evaluation board in T0247 packages

## EVAL-M5-IGBT7

### About this document

#### Scope and purpose

This application note provides an overview of the evaluation board EVAL-M5-IGBT7 including its main features, key data, pin assignments, mechanical dimensions, and corresponding control card.

The EVAL-M5-IGBT7 is a complete evaluation board including the six discrete IGBTs realizing a B6 inverter for motor drive applications. In combination with control boards equipped with the M5 32-pin interface connector such as the XMC DriveCard 4400, it features and demonstrates Infineon's IGBT in motor drives.

The evaluation board EVAL-M5-IGBT7 was developed to support customers during their first steps in designing applications with IGBT.

#### Intended audience

This application note is intended for power electronic engineers evaluating the use of IGBT devices in drive applications.

# 1 Safety precautions

In addition to the precautions listed throughout this manual, please read and understand the following statements regarding hazards associated with development systems.

Table 1 Safety Precautions

	<p><b>Attention:</b> The DC link potential of the EVAL-M5-IGBT7 system is connected to the grid input. When measuring voltage waveforms by oscilloscope, high voltage differential probes must be used. Failure to do so may result in personal injury or death. Darkened display LEDs are not an indication that capacitors have discharged to safe voltage levels.</p>
	<p><b>Attention:</b> EVAL-M5-IGBT7 system contains DC bus capacitors which take time to discharge after removal of the main supply. Before working on the drive system, wait five minutes for capacitors to discharge to safe voltage levels. Failure to do so may result in personal injury or death. Darkened display LEDs are not an indication that capacitors have discharged to safe voltage levels.</p>
	<p><b>Attention:</b> Only personnel familiar with the drive and associated machinery should plan or implement the installation, start-up and subsequent maintenance of the system. Failure to comply may result in personal injury and/or equipment damage.</p>
	<p><b>Attention:</b> The surfaces of the drive may become hot, which may cause injury.</p>
	<p><b>Attention:</b> EVAL-M5-IGBT7system contains parts and assemblies sensitive to Electrostatic Discharge (ESD). Electrostatic control precautions are required when installing, testing, servicing or repairing this assembly. Component damage may result if ESD control procedures are not followed. If you are not familiar with electrostatic control procedures, refer to applicable ESD protection handbooks and guidelines.</p>
	<p><b>Attention:</b> A drive, incorrectly applied or installed, can result in component damage or reduction in product lifetime. Wiring or application errors such as under sizing the motor, supplying an incorrect or inadequate AC supply or excessive ambient temperatures may result in system malfunction.</p>
	<p><b>Attention:</b> Remove and lock out power from the drive before you disconnect or reconnect wires or perform service. Wait five minutes after removing power to discharge the bus capacitors. Do not attempt to service the drive until the bus capacitors have discharged to zero. Failure to do so may result in personal injury or death.</p>
	<p><b>Attention:</b> EVAL-M5-IGBT7system is shipped with packing materials that need to be removed prior to installation. Failure to remove all packing materials which are unnecessary for system installation may result in overheating or abnormal operating condition.</p>

Introduction

## 2 Introduction

The EVAL-M5-IGBT7 evaluation board is a part of the iMOTION™ Modular Application Design Kit for motor drives. These boards can easily be interfaced via the iMOTION™ MADK-M5 32-pin interface connector to control boards such as the XMC DriveCard 4400 or XMC DriveCard 1300. Infineon provides a demonstration program provided with XMC Drive Card 4400 platform, to control a mother board and demonstrates Infineon’s IGBT in motor drives.

This evaluation board is designed to be an easy-to-use power stage based on Infineon's discrete power IGBTs. The board is equipped with all assembly groups for sensorless field oriented control (FOC). It provides a three-phase AC-connector, EMI filter, rectifier, and a 3-phase output for connecting the motor. The power stage also contains isolated current, voltage, and temperature sensing circuits.

The features of this board are described in the design feature chapter of this document, whereas the remaining paragraphs provide information to enable the customers to copy, modify and qualify the design for production according to their own specific requirements.

Environmental conditions were considered in the design of the EVAL-M5-IGBT7. The design was tested as described in this document but not qualified regarding safety requirements or manufacturing and operation over the whole operating temperature range or lifetime. The boards provided by Infineon are subject to functional testing only. Evaluation boards are not subject to the same procedures as regular products regarding Returned Material Analysis (RMA), Process Change Notification (PCN) and Product Discontinuation (PD). Evaluation boards are intended to be used under laboratory conditions and by trained specialists only.

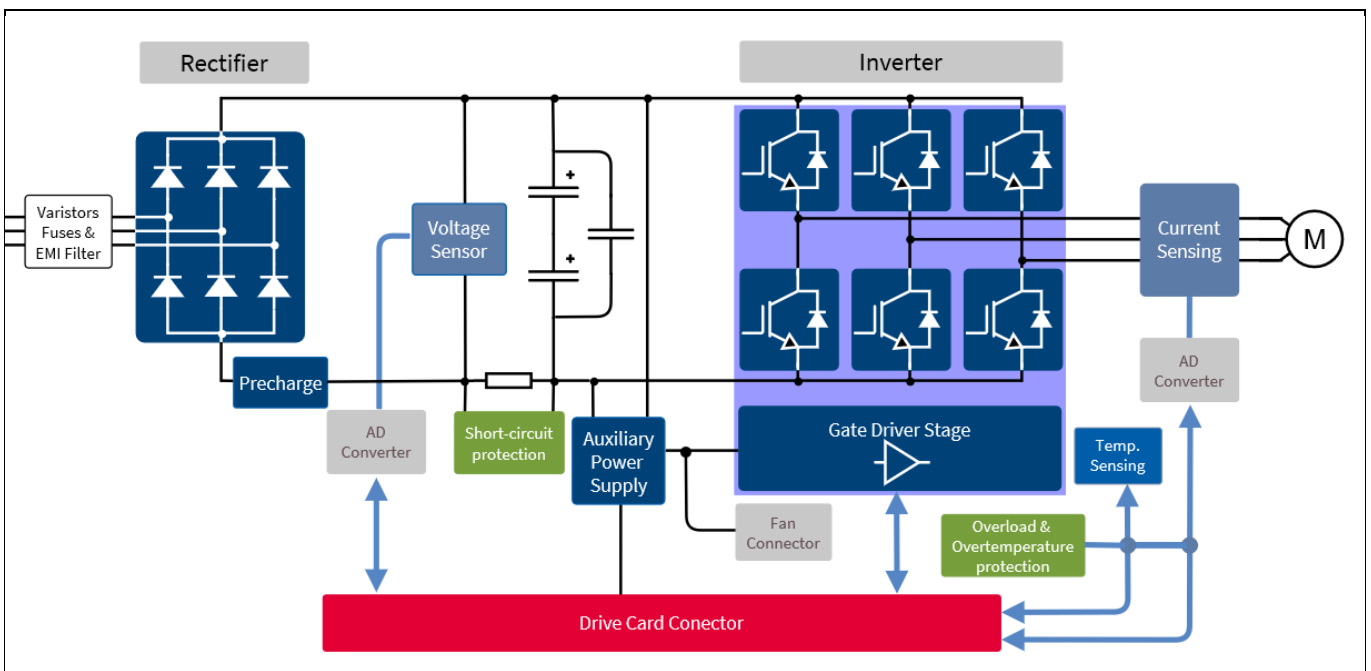

Figure 1 The block diagram of the EVAL-M5-IGBT7

The block diagram of the EVAL-M5-IGBT7 is depicted in Figure 1. This evaluation board includes an EMI filter, a line rectifier with a soft power up circuit, an auxiliary power supply to provide 5 V, and the IGBTs. All measuring and control signals are available on a 32-pin drive card interface connector. The hardware circuit regarding overtemperature and overcurrent protection is also included in this power board.

## **Introduction**

The signal part of this evaluation board is fully separated from the power part by basic insulation. Whereas the power components are on grid potential, the signal part is earthed by the input connector. The design can be upgraded easily to safe electrical insulation by replacing the present IGBT drivers (X.U150, X.U151) and the auxiliary power supply transformer (T650) by parts with an appropriate safety approval.

Main features

### 3 Main features

The EVAL-M5-IGBT7 is an evaluation board for motor drive applications comprising IGBT technology. Combined in a kit with one of the available MADK control board options, it demonstrates Infineon’s IGBT power technology used in discrete IGBT.

**The evaluation board characteristics are:**

- Input voltage 340~480 V<sub>AC</sub>
- Peak 11 kW motor power output
- On board EMI filter
- Basic insulation between power and signal part
- Isolated current sensing with  $\Delta\Sigma$ -ADC
- Isolated sensing of dc-link voltage by  $\Delta\Sigma$ -ADC
- Thermistor output
- Overload and short-circuit hardware protection
- Overtemperature hardware protection
- All six switches turn off during protection
- Rugged gate driver technology with stability against transient and negative voltage
- Auxiliary power supply with 5 V
- Measurement test-points compatible with standard oscilloscope probes
- PCB is 259 mm x 204 mm and has four layers with 35 $\mu$ m copper each
- RoHS complaint

Table 2 depicts the important specifications of the evaluation board EVAL-M5-IGBT7 for IKW40N120CS7 device.

### 3.3 Analog measurement adjustment

To achieve precise measurement of the output currents and a symmetric overcurrent detection, the offset voltage of the analog signals must be adjusted. All relevant parts for the adjustment of the offset voltage are shown in Figure 3.

Main features

**Figure 3** Relevant parts for offset adjustments

The DC-bus voltage measurement has only a small deviation, consequently, there is no offset compensation necessary. To adjust the current offset simply vary R554 at no load until either the software readings of the currents are zero or the voltages at the currents' test points reach almost 2,5 V. Due to component tolerances an exact adjustment of all three currents to zero at the same time will not be possible. Additional Information about the circuit itself can be found in the chapter "5.9 Analog to digital converter".

## 4 Demo control

The IGBT platform is intended for use with various power stages with different control boards. These boards can easily be interfaced via the iMOTION™ MADK-M5 32-pin interface connector to control boards such as the XMC DriveCard 4400 or XMC DriveCard 1300. Infineon provides a demonstration program provided with XMC Drive Card 4400 platform, to control a mother board and demonstrates Infineon's IGBT in motor drives. A detailed description of the XMC4400 drive card can be found online:

[https://www.infineon.com/cms/en/product/evaluation-boards/kit\\_xmc4400\\_dc\\_v1/](https://www.infineon.com/cms/en/product/evaluation-boards/kit_xmc4400_dc_v1/)

### 4.1 Installing DEMO Guide User Interface (GUI)

Infineon provides a GUI control for this board for demonstration purpose only. Please note that such control is only for easiness to use the MADK board, only limited functions and protections are included. Infineon cannot provide extra technical supports for code modification.

This section describes how to install the Infineon DEMO GUI and what are the pre-required softwares that need to be installed, before using the software.

Prerequisites for usage of DEMO GUI from Infineon (follow the instructions from provider to install):

- Windows 10 Enterprise
- User interface for programming target Flash memory, like the “J-Flash Lite” that is a part of the J-Link software pack, available here:  
<https://www.segger.com/downloads/jlink/#JLinkSoftwareAndDocumentationPack>
- XMCTM Flasher tool for XMCTM MCU Flash programming:  
<https://www.infineon.com/cms/en/product/microcontroller/32-bit-industrial-microcontroller-based-on-arm-cortex-m/#!tools>
- The latest version of Microsoft .NET Framework
- Infineon GUI software package provided with the setup (unzip to preferred location) or download it from the website
- Micro USB cable Type-B

**Demo control**

- XMC 4400 operate only when a 5 V is applied to the pins A1 and B1 (Evaluation board has included internal power supply)

**Figure 5 GUI execution files**

When provided package is unzipped, the user needs to install the software package called **IFX Inverter Control Setup**. The user should be able to use the software in 8 easy steps as presented below.

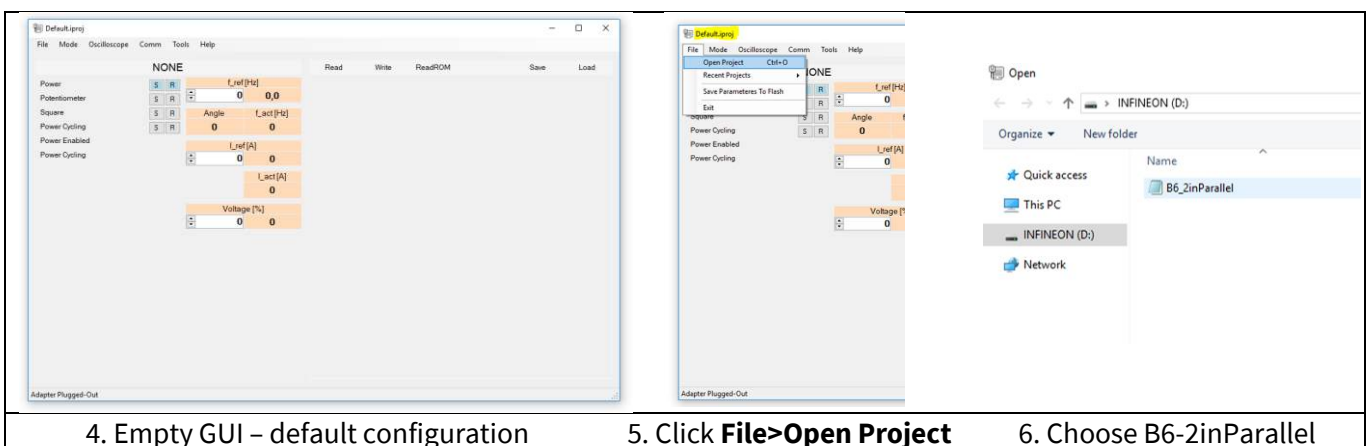

1. Click Install

2. Click Finish

3. Software Icon

**Figure 6 Installation process of IFX Inverter Control Setup software**

While opening the IFX Inverter Control Setup, by default an empty GUI with no parameters is available. Therefore, it is necessary to open a provided GUI configuration like it is shown in Figure 7.

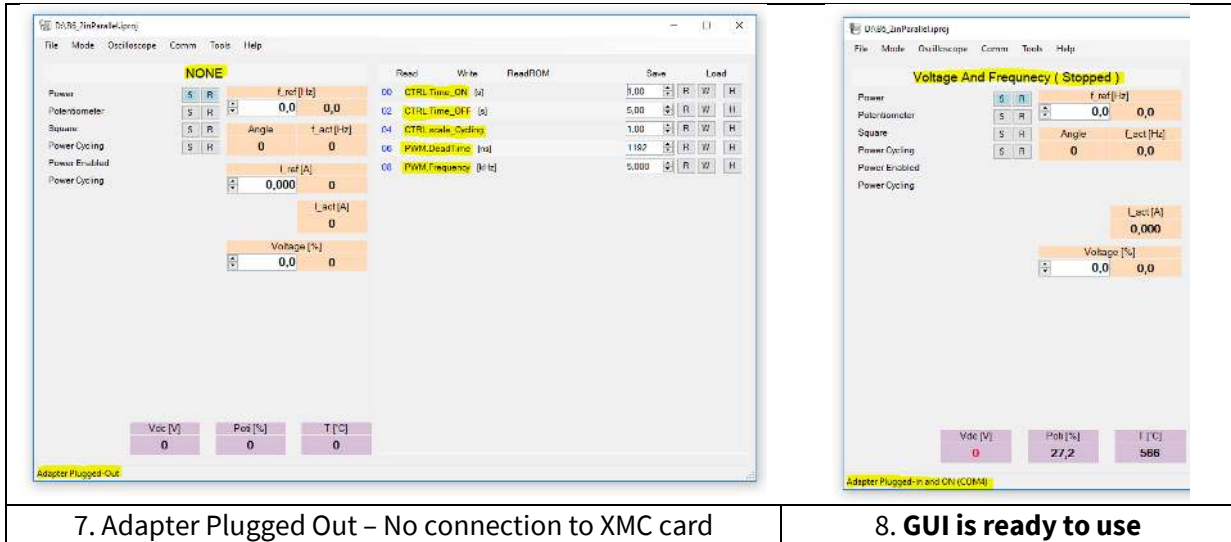

4. Empty GUI – default configuration

5. Click **File>Open Project**

6. Choose B6-2inParallel

**Figure 7 Configuration of Infineon DEMO Graphical User Interface**

Infineon’s software gives users a feedback about the current status, if any devices are connected to the GUI (computer) as shown in Figure 8 (NONE – board is connected). The same indication is written at the below of the software as Adapter Plugged Out.

7. Adapter Plugged Out – No connection to XMC card

8. GUI is ready to use

**Figure 8 Inactive Software – No board connected to the computer**

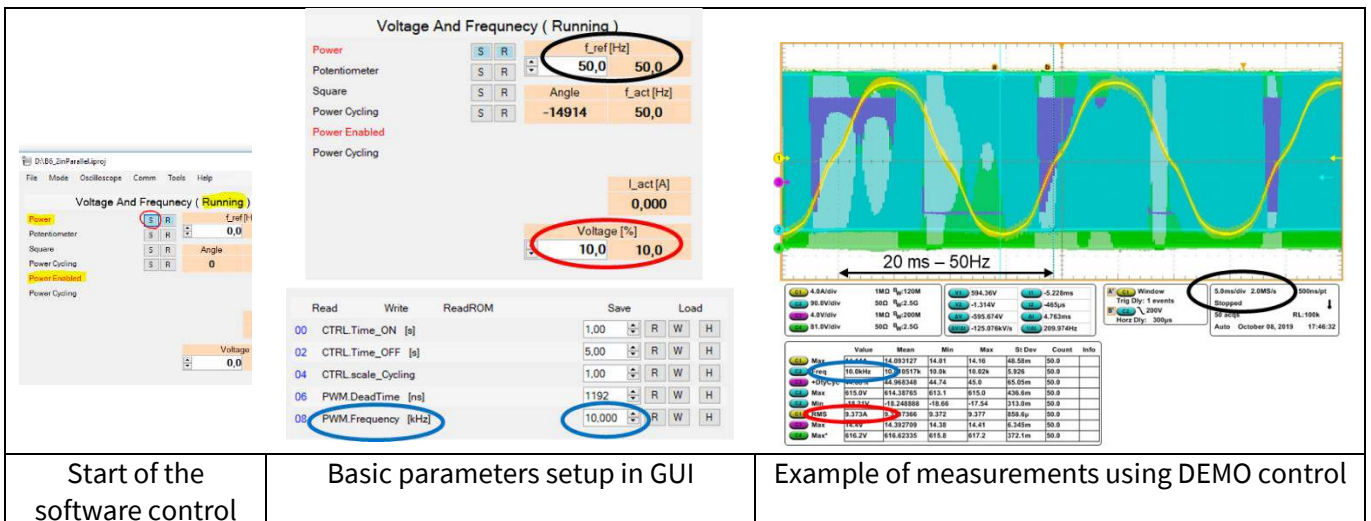

When the XMC driver card is connected with the computer, the software automatically recognizes the controller. The software will show the status Adapter Plugged-in and ON (COMX). The software needs to be restarted in case of connecting the controller, when the software has been started before.

### 4.2 Using the DEMO Guide User Interface for IGBT MADK

By following the instructions in previous sections, the user could start operating now the IGBT motor drives evaluation board with provided demo software.

This section will show an example, how to use Infineon ´s DEMO GUI for controlling the evaluation board and test the performance of IGBTs in the motor drive application.

Figure 9 illustrates a step by step process of an example, how to use the DEMO control in the application

**Figure 9 Example 1 – Changing main parameters of the Infineon DEMO control**

The user has the possibility to change four basic parameters of the DEMO control:

- Phase fundamental/current frequency [Hz],
- Voltage Duty Cycle [%],

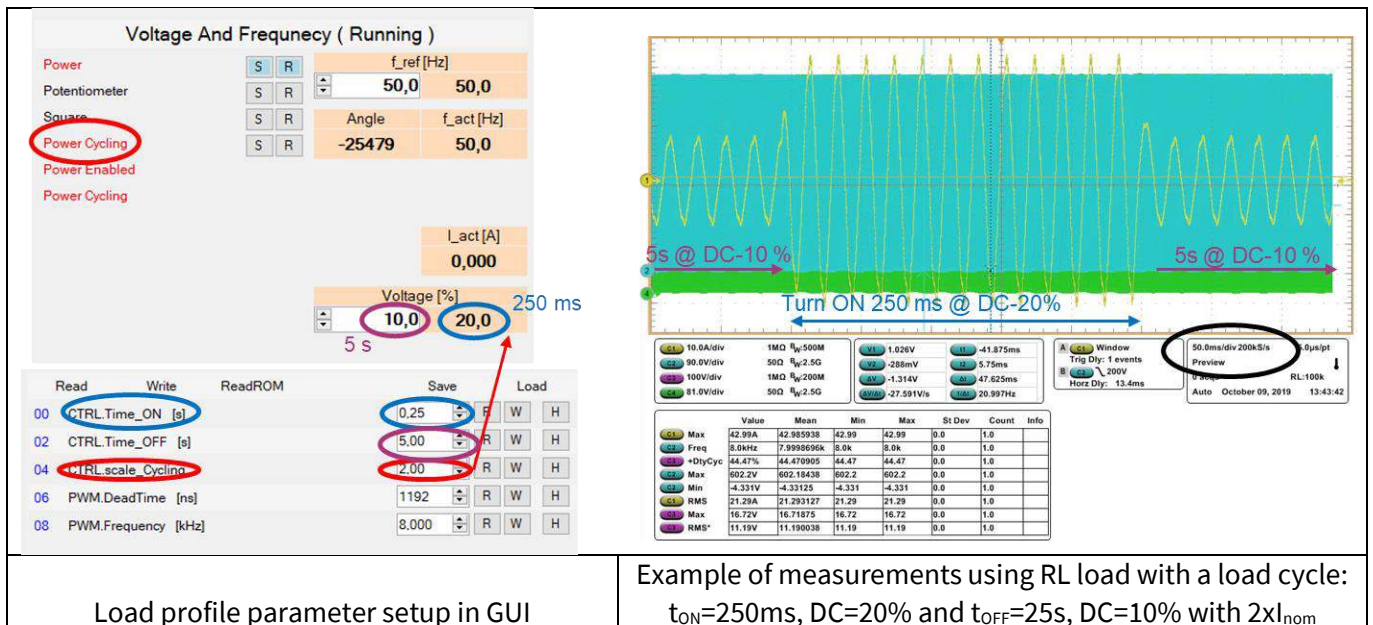

# User Manual

## EVAL-M5-IGBT7

### Demo control

- Switching frequency [kHz],
- Dead Time [ns]

In addition the user can define a different testing load profile by changing two time periods and the scale factor of duty cycle. Figure 10 shows an example, how to create a testing load profile. This allows to test the devices at different load profiles, like the 3xInom, for a short time pulse.

Load profile parameter setup in GUI

Example of measurements using RL load with a load cycle:  $t_{ON}=250ms$ ,  $DC=20\%$  and  $t_{OFF}=25s$ ,  $DC=10\%$  with  $2xI_{nom}$

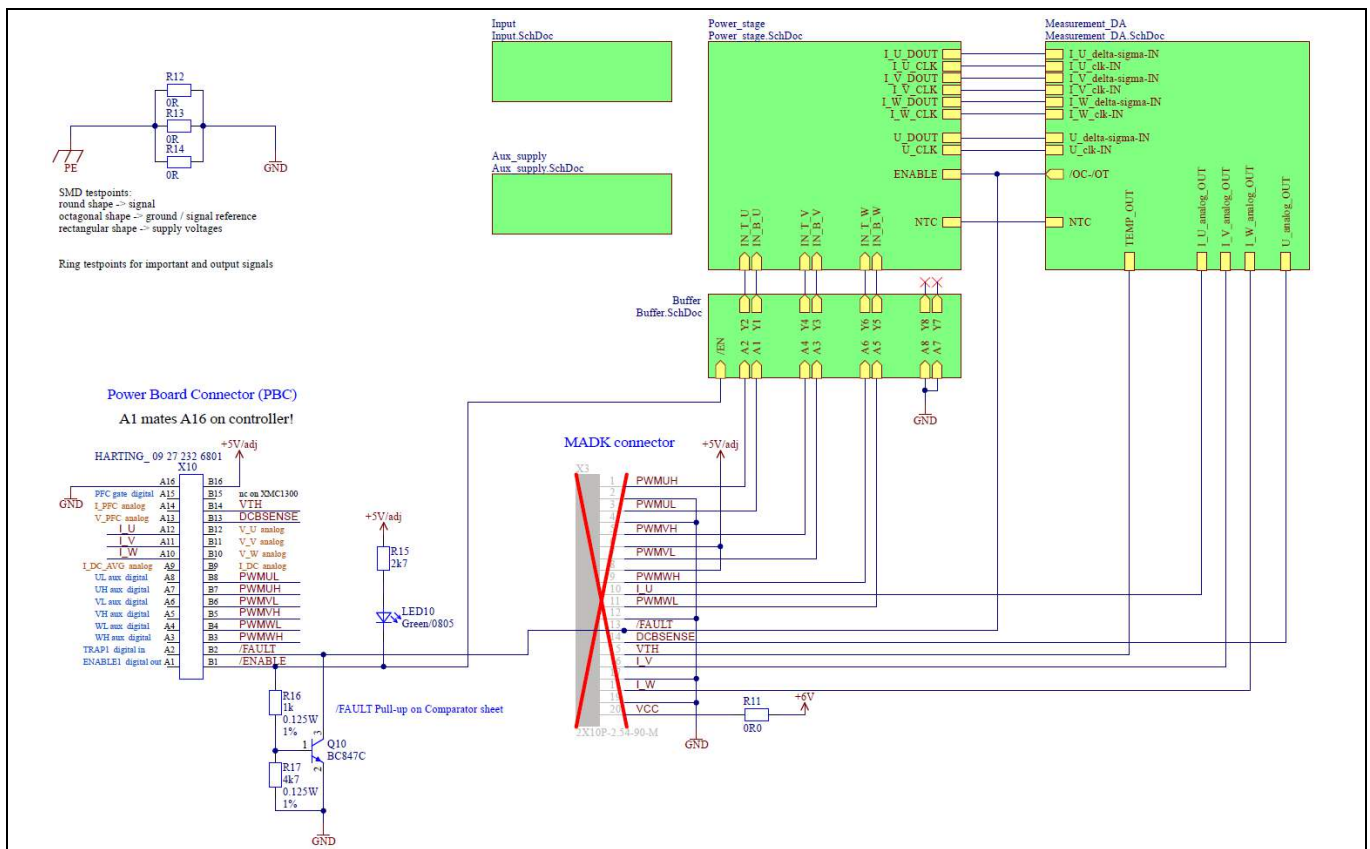

**Figure 10 Example 2 – Defining a load profile with Infineon DEMO control**

## 5 Schematics and Layout

### 5.1 Overview

An overview of the board's schematics is given in Figure 11. The schematic can be divided into four subcategories: the input circuit of the converter, the auxiliary supply, the power stage, and the measurements. The external controller board has to be connected to the evaluation board by the driver board connector X10. The logical ground is connected to the earth by the resistors R12 to R14. Alternatively, the board can be equipped with an iMOTION™ MADK M1 20 pin interface connector in a different population variant.

**Figure 11 Overview and driver board connector**

### 5.2 Input Circuit

The input circuit is shown in Figure 12. It is equipped with two NTC resistors, which limit the inrush current. The resistors are bypassed after the start of the auxiliary supply and a constant delay time. The DC-bus consists of four electrolytic capacitors and one film capacitor as well as four ceramic capacitors for the high frequency ripple currents. The electrolytic capacitors are series connected and balanced with two resistors.

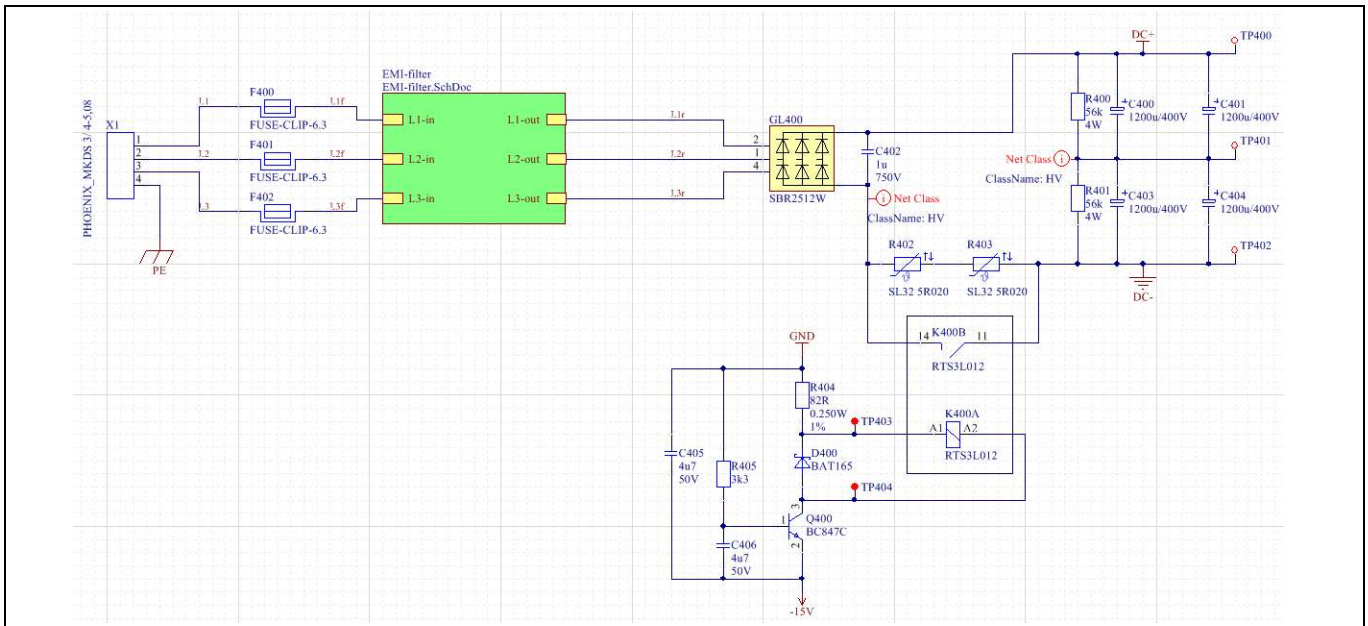

Figure 12 Mains input and precharge circuit

### 5.2.1 EMI Filter

The EVAL-M5-IGBT7 is equipped with an EMI filter circuit. The circuit is depicted in Figure 13.

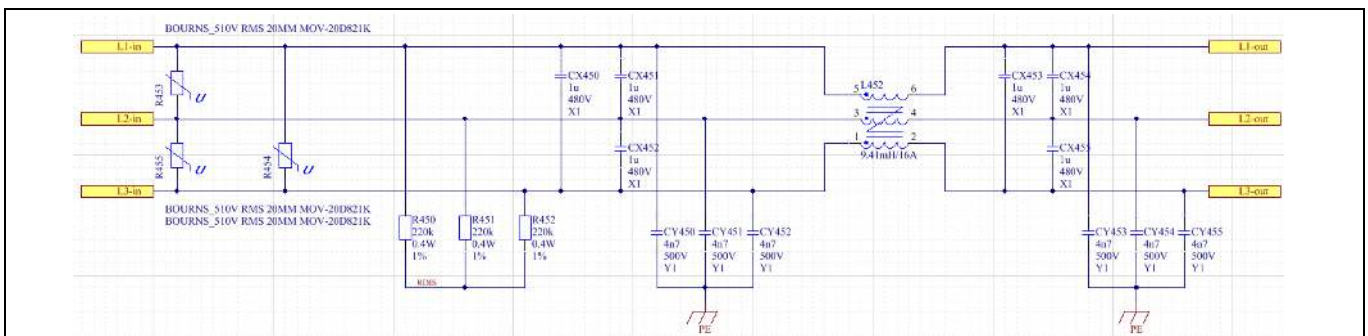

Figure 13 EMI Filter

The EMI filter is designed to minimize high-frequency emissions to the connected grid. Lower harmonics of the grid current are not suppressed! Additional mains line choke must be used to fulfill harmonic standards! In addition, a mains line choke also reduces the crest factor of the input current. Hence, an external choke allows higher RMS input currents leading to higher output power. Without an additional mains line choke an output power of approx. 6 kW can be achieved at 400 V line voltage.

However, the conducted EMI emission strongly depends on several operating conditions, like the connected motor, used switching frequency and so on. Consequently, the implemented filter not necessarily fulfill the required standard. If necessary a Vacuumschmelze W 424-53 ring core, or similar, with three turns can be added to the supply lines as a common mode choke to further reduce the conducted EMI.

### 5.3 Auxiliary Supply

All supply voltages are generated by a flyback converter, supplied from the DC-bus. It starts operation at a bus voltage of  $477 V_{dc}$ , which corresponds to approximately  $340 V_{ac}$  input voltage. The supply circuit is realized with an Infineon ICE5QSAG control IC. To modify brownin voltage (e.g. to use 650 Voltage class devices) tune the

voltage divider (R668) according to ICE5QSAG datasheet. The supply voltages are isolated from the DC-bus potential by basic insulation. The complete schematic is shown in Figure 14.

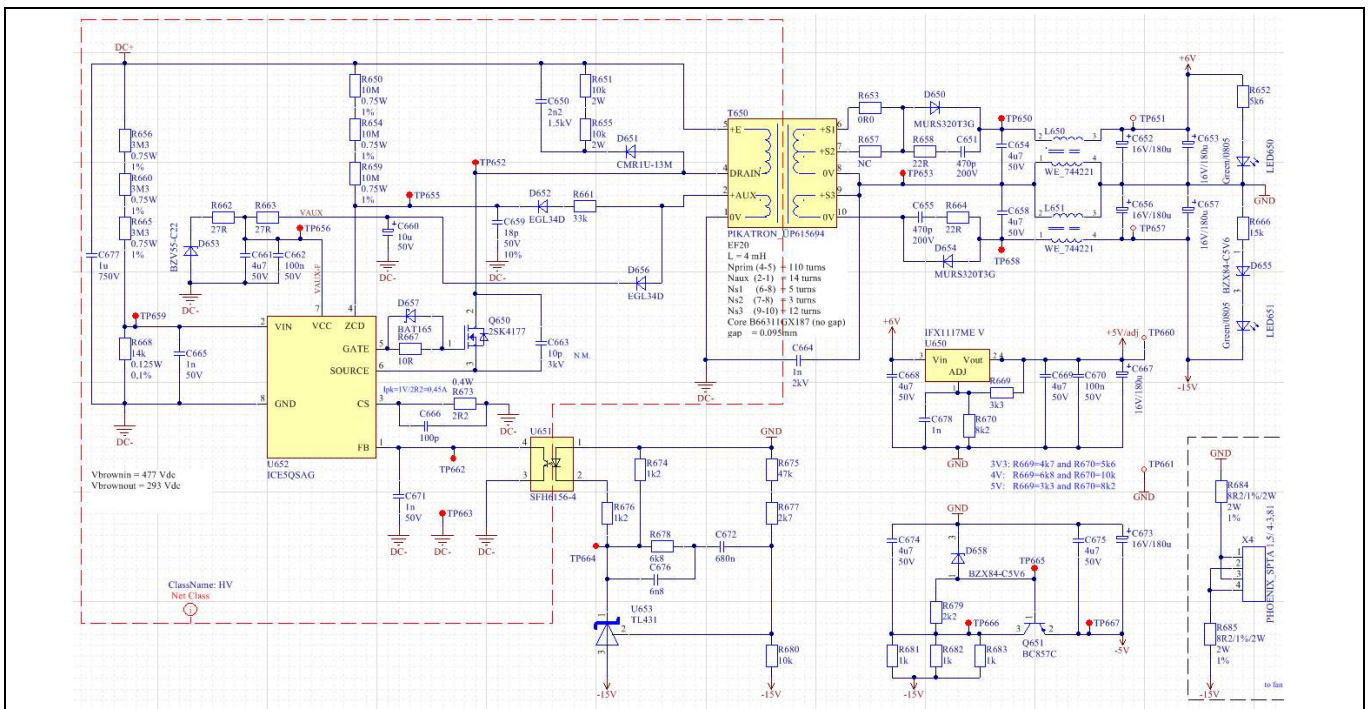

Figure 14 Auxiliary supply

The flyback converter generates three voltages. The auxiliary winding on the primary side of the transformer generates an unregulated 17.6 V supply for the control IC itself. On the transformer's secondary side two output voltages are generated: a regulated -15 V and indirect regulated +6 V. The -15 V supply voltage is mainly used for the IGBT driver supply circuit. From this voltage, a -5 V supply voltage is derived by a linear regulator used for the negative supply for the analog circuitry of the board. The positive analog supply is directly connected to the +6 V supply. This voltage rail is also used to generate the +5 V for the controller and overcurrent threshold generations.

If the EVAL-M5-IGBT7 is to be used with low DC-bus voltages below the brown in threshold of the flyback converter it is possible to supply it with an external power supply. Therefore, the test points TP651, TP656, and TP661 can be used. These test points are labeled with their corresponding voltage on the PCB. The points are depicted in Figure 15.

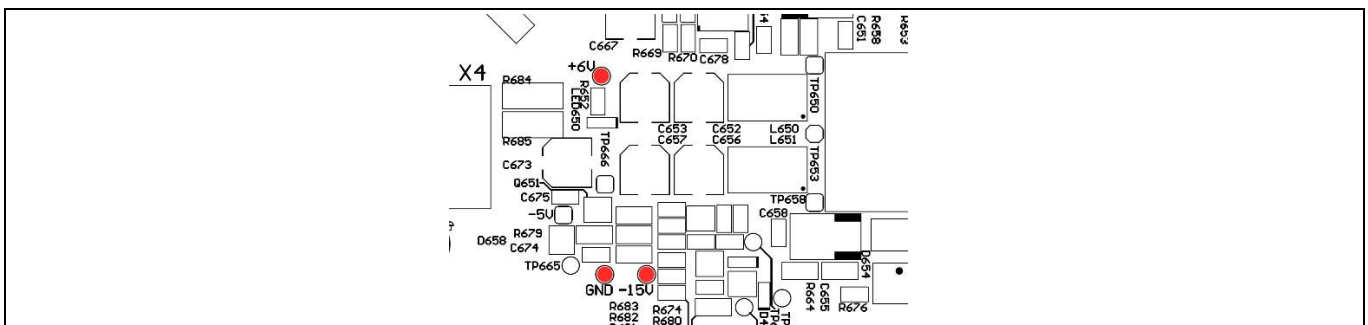

Figure 15 Major power supply test points

## 5.4 Power Stage

The schematic of the power stage is shown in Figure 16. The three-phase legs are connected to one film capacitor and four ceramic capacitors. Two of the ceramic capacitors are connected directly to the power switches prior to the current measuring shunt. For the film capacitors, two alternate packages can be mounted. Both high-frequency capacitor types are placed as close as possible to the power switches to minimize overvoltage at switching. Only two of the ceramic capacitors are connected prior to the shunt to limit short circuit energy. The DC-bus is led through to the connector X6.

The current measuring shunt is used to detect output short-circuits. An overcurrent protection circuit is used to monitor the shunt voltage and to disable all switches in an overcurrent condition.

At each phase, the output current is measured by a shunt resistor. The shunt voltages are measured by galvanic isolated DS-ADCs. Their supply is derived from an additional voltage level of the top-side driver supply circuit. The voltage of the DC-bus is measured by a voltage divider and the same isolated DS-ADC supplied from an additional driver voltage of the low-side driver supply. The functionalities of these blocks are explained below. An NTC can be mounted on the heatsink for generating a temperature-related measuring voltage  $V_{th}$ .

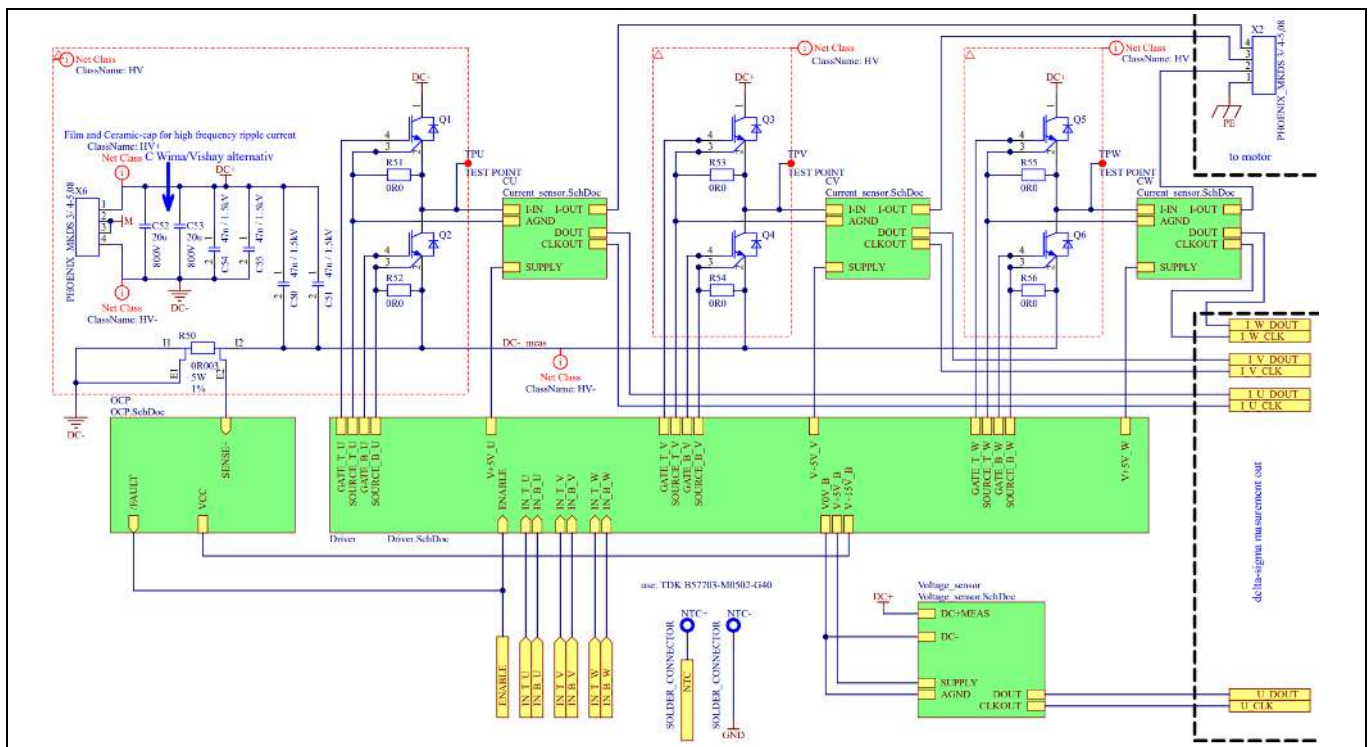

Figure 16 Power stage

## 5.5 Driver Circuit

Each of the six IGBTs is driven by Infineon’s IGBT EiceDRIVER™ 1EDI20H12AH. The positive input is protected by an additional glitch filter and a pull down resistor. All negative inputs are connected and are used for a global /ENABLE signal. The circuit, which is used for each phase leg, is shown in Figure 17.

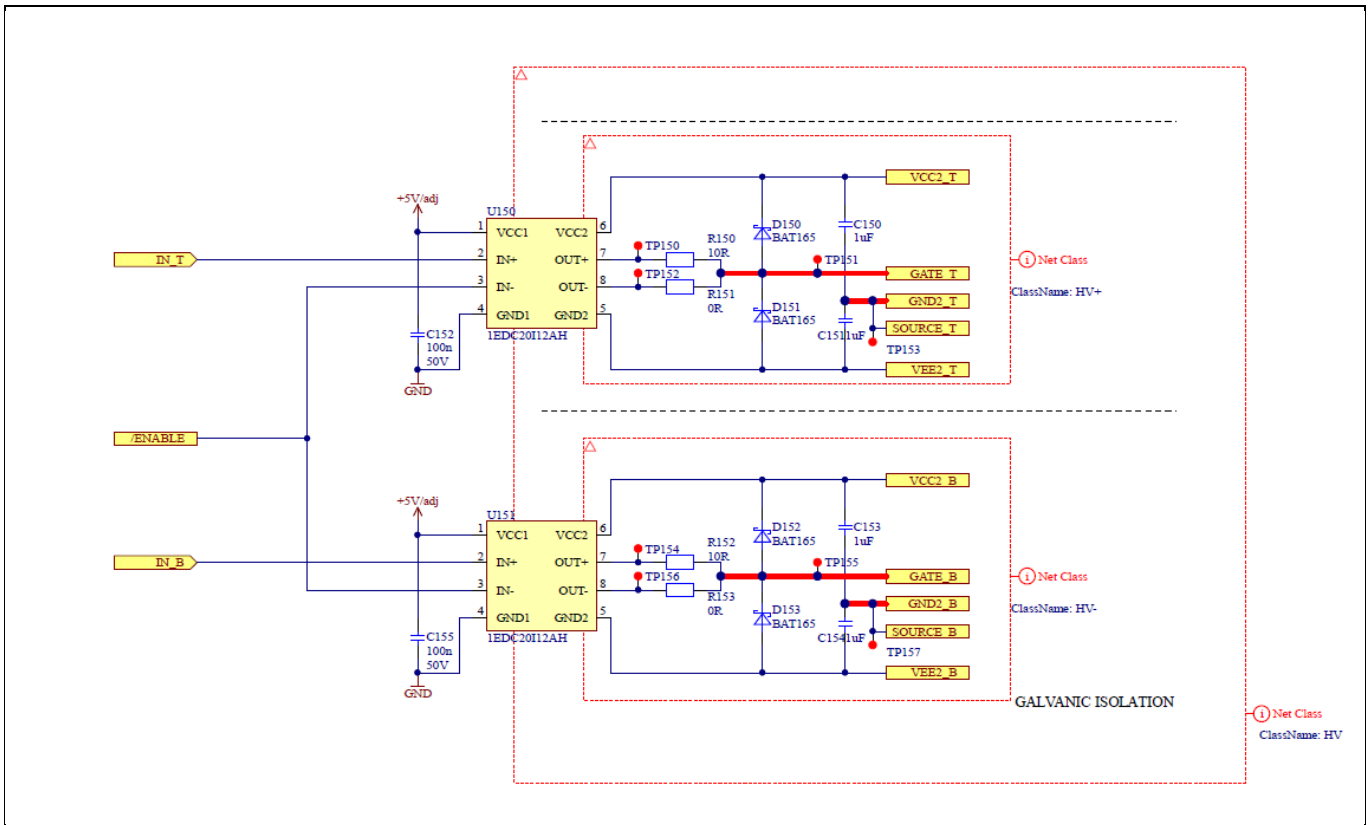

Figure 17 Driver circuit for one phase leg

The secondary sides of the EiceDRIVER™ are supplied by four galvanic isolated power supplies: one for each top-side driver including the current sensor supply and one for all low-side drivers together with the voltage sensor. The whole circuit is shown in Figure 18. The four output voltages are generated by two impulse transformers, which are supplied by a high-frequency oscillator. At each output, a rectifier is located which generates three different voltage levels.

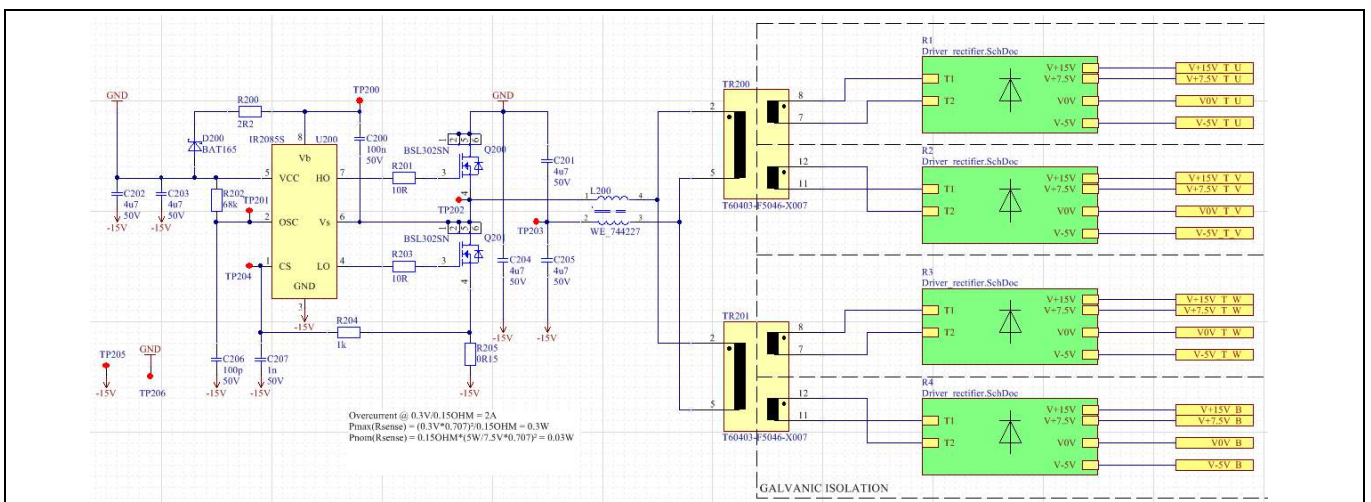

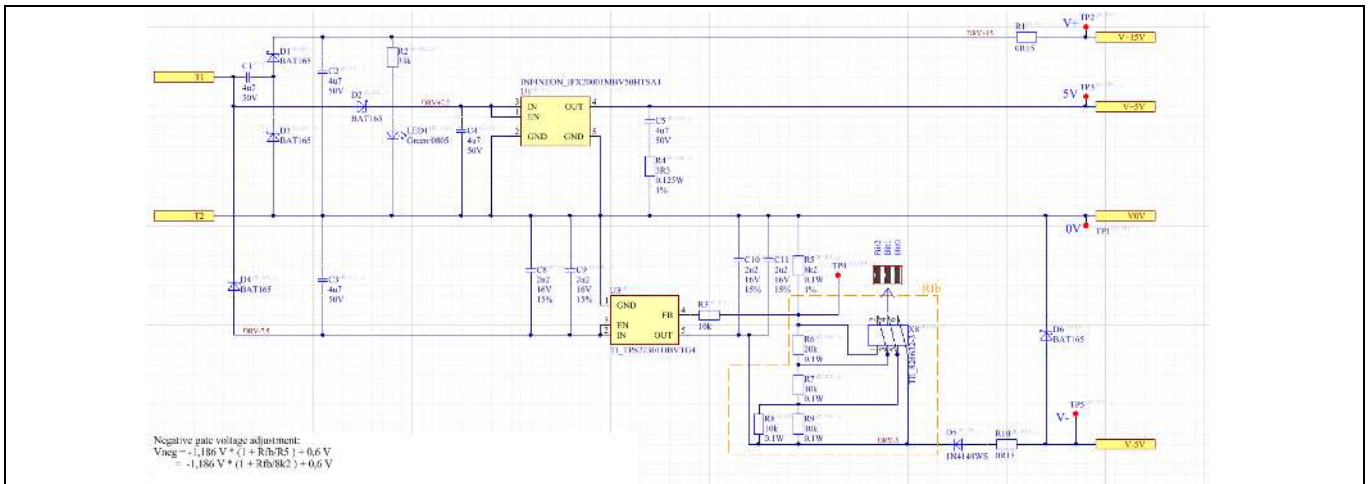

Figure 18 Driver power supply

The rectifier circuit generates three voltage levels for each driver: a regulated negative voltage for safe turning off the power IGBT, +15 V for turning on the power IGBT, and additionally +5 V for the additional current and voltage measurement. The circuit is shown in Figure 19.

**Figure 19 Rectifier circuit of driver power supply**

The regulated negative voltage can be adjusted in 8 steps by placing jumpers on the pin header X8. This adjustment must be done for each rectifier circuit separately. By placing the jumpers the feedback resistor of the negative voltage regulator is changed. Consequently, its output voltage can be adjusted. The selectable voltages are shown in Table 10.

Additionally, it is possible to use real 0 V turn off voltage if R10 is removed and TP1 is connected to TP5. Be careful with adjusting the negative voltage! Load conditions might occur, which lead to undesired turn on of the power switches.

## 5.6 Thermistor Output

The temperature of the heatsink is measured with a TDK B57703-M0502-G40 NTC resistor. The NTC resistor is connected to 5 V via a series resistor of 10 kΩ. The resulting NTC voltage is fed to the control board via an amplifier with a gain of 2. If necessary the signal level can be changed by exchanging the resistors R617, R620, R621, and R623. The evaluation circuit is depicted in Figure 20.

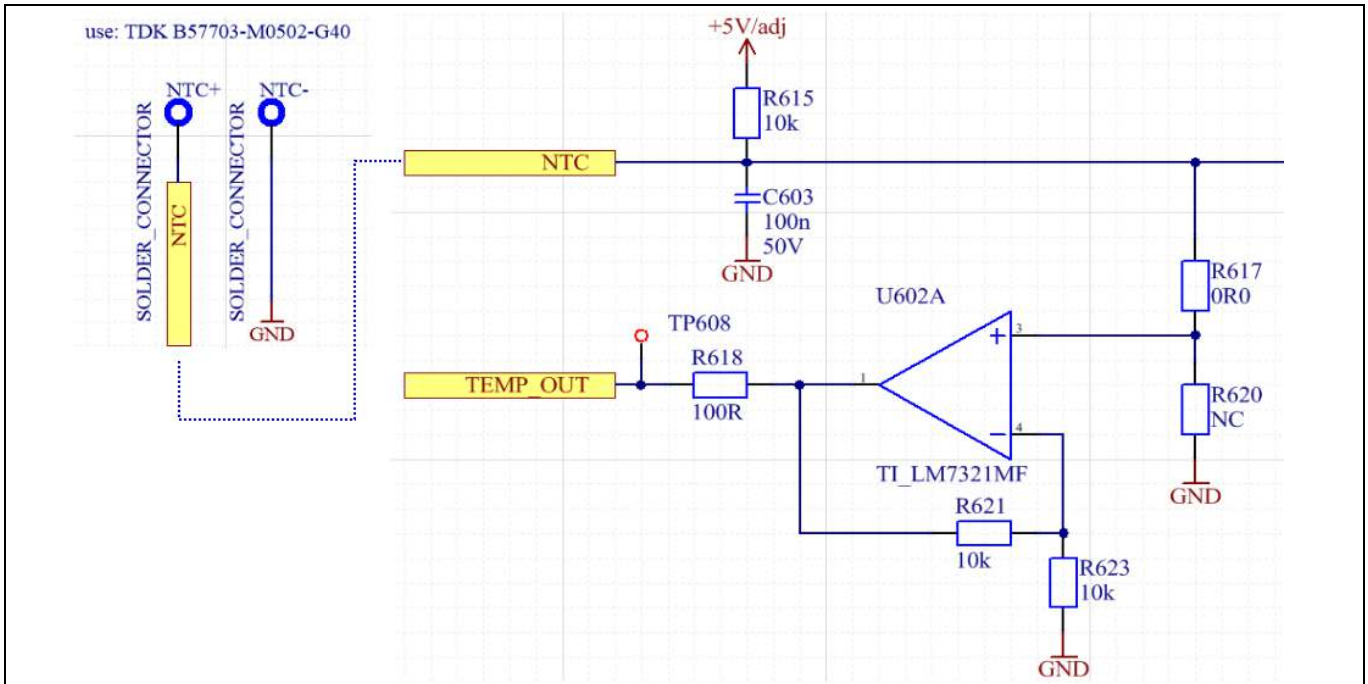

Figure 20 Evaluation circuit for NTC measurement

The dependency of the generated output voltage vs. the heatsink’s temperature when using a TDK B57703-M0502-G40 NTC resistor is shown in Figure 21.

Figure 21 Heatsink temperature output

### 5.7 Current Measurement

The three phase currents are measured by shunt resistors. Each shunt voltage is measured by a galvanic isolated  $\Delta\Sigma$ -modulator. The modulator generates a  $\Delta\Sigma$ -modulated bit stream output with a clock frequency of 20 MHz. The circuit can be seen in Figure 22. The modulator is supplied via the +5 V output from the rectifier circuit.

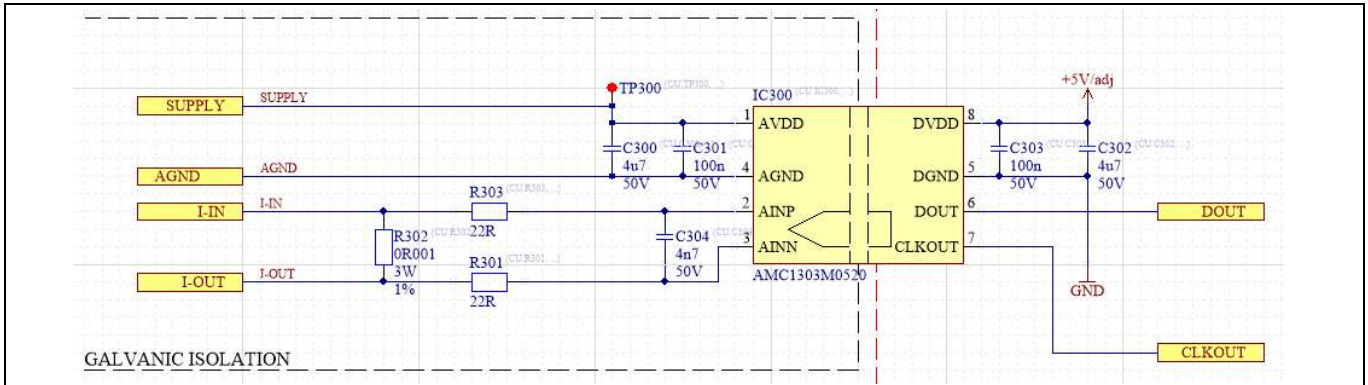

Figure 22 Phase current measurement

### 5.8 Voltage Measurement

Similar to the current measurement the DC-bus voltage is measured via a voltage divider and the galvanic isolated  $\Delta\Sigma$ -modulator.

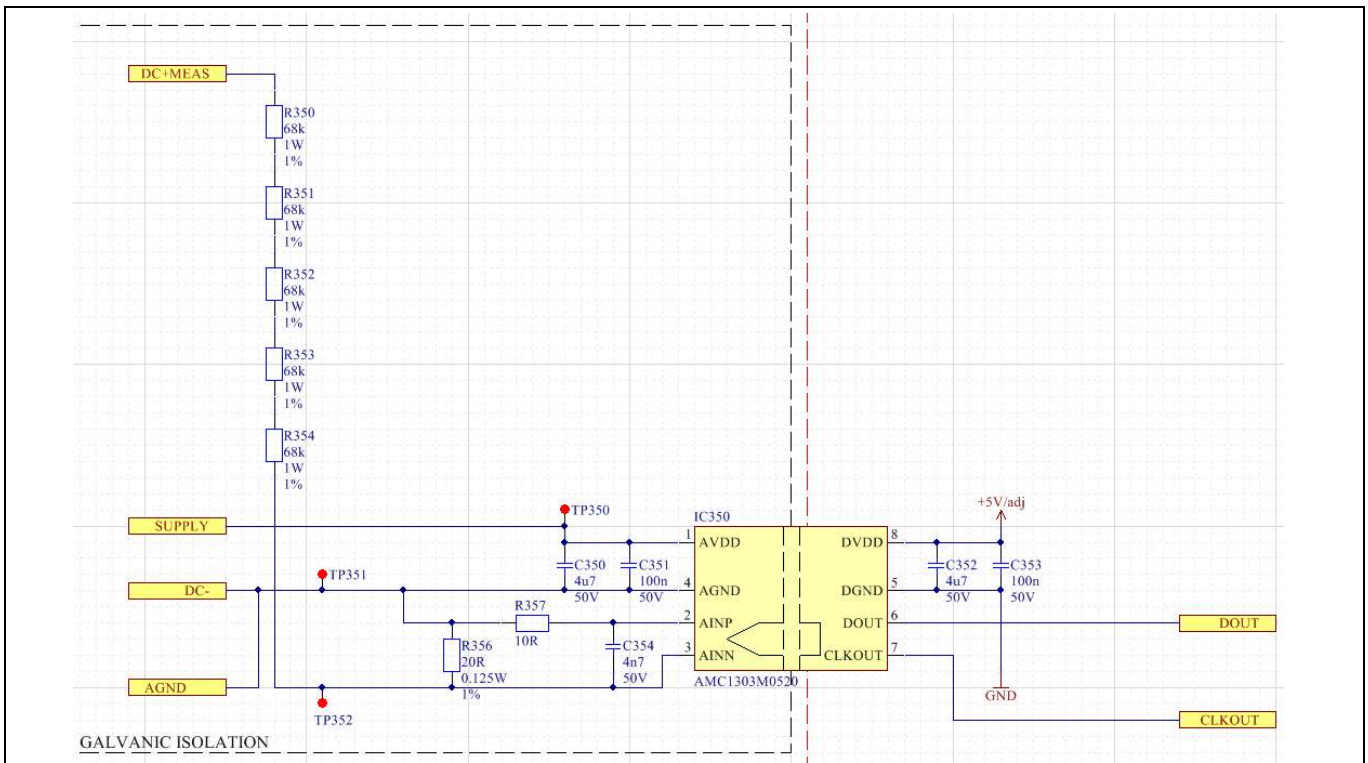

Figure 23 DC-bus voltage measurement

## 5.9 Analog to digital converter

The evaluation board contains four discrete analog to digital converters to generate analog signals from the digital  $\Delta\Sigma$ -modulated bit streams. The analog signals are used for the on-board protection as well as for the external controller. The conversion is done by 2<sup>nd</sup> order low pass filters with approximately 6.5 kHz bandwidth. At zero input the  $\Delta\Sigma$ -converter generates a bit stream with 50% duty cycle. For offset adjustment, the reference voltage of the low pass filters can be adjusted via the potentiometer R556 for all three currents. The four  $\Delta\Sigma$ -modulated bit streams can be measured directly at the pin headers X7.

## 5.10 Overload and Overtemperature Protection

The EVAL-M5-IGBT7 evaluation board is equipped with overcurrent and overtemperature protection. If an overcurrent or overtemperature event is detected the /FAULT signal is pulled low and the IGBT drivers are simultaneously disabled for around 30 ms.

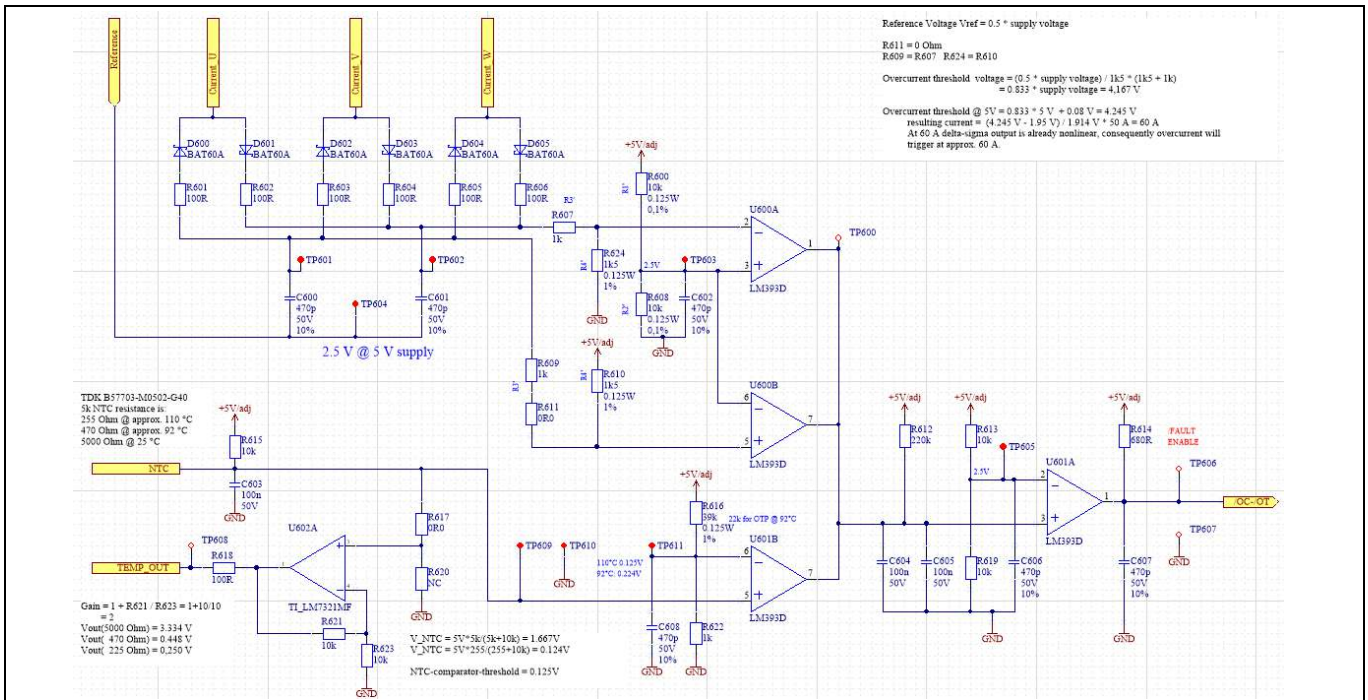

Figure 25 Protection circuit and temperature measurement

The overcurrent detection is realized with six ultra-low forward voltage drop diodes (D600 ... D605), which rectify the peak current of each phase. The peak positive value and the peak negative value are compared with a threshold value. If one is exceeded the /FAULT signal is triggered.

The overtemperature detection monitors directly the NTC voltage. A voltage below 0.125 V triggers the /FAULT signal. This threshold corresponds to a measured heatsink temperature of  $110^\circ\text{C}$ .

### 5.11 Overcurrent / Short Circuit Protection

The circuit, which monitors the voltage across a 3 mΩ shunt placed in the DC path of the power IGBT, is shown in Figure 26. A low side driver with an overcurrent protection feature is used here. The driver stage itself is unused. The Infineon 1ED44176N01F has 0.5 V overcurrent trigger threshold. This leads to a nominal current threshold of 167 A.

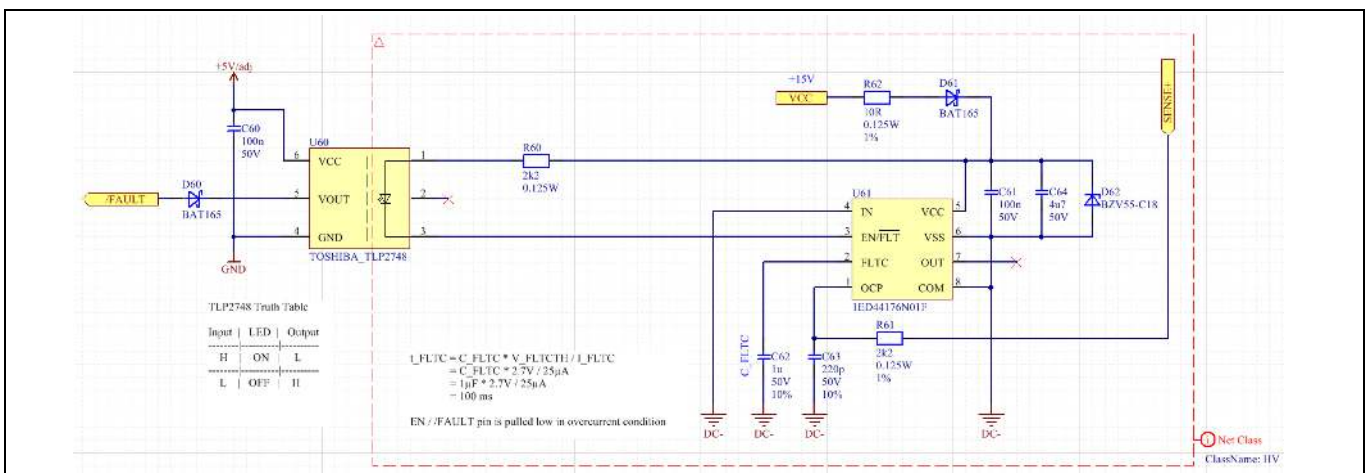

Figure 26 Short-circuit protection

**Schematics and Layout**

A low pass filter (R61/C63) is placed at the OCP pin of the IC. Its time constant of 484 ns is required to block high voltage spikes at fast current rises due to the parasitic inductance of the measuring shunt and its connection. If an overcurrent is detected the EN/FAULT pin of the driver is pulled low and the LED of the connected optocoupler turns on. Hence, the isolated side of the optocoupler turns low and the /FAULT signal is pulled low. Consequently, all IGBT drivers are turned off. The overall time delay from overcurrent to IGBT gate low is approximately 1  $\mu$ s.

The circuit is supplied via the low-side gate driver supply. This supply is referenced to the emitter of the low-side IGBTs which is before the shunt. Consequently, the supply of the OCP protection is decoupled with a diode (D61) and buffered with a capacitor (C64). This leads to a voltage drop of approximately 1 V in overcurrent condition but this is still sufficient to supply the circuit.

**5.12 PCB Layout**

The layout of this board is especially designed for evaluation purposes. Consequently, it has a lot of test points on it and is not necessarily suited for continuous operation at full load. The PCB has four electrical layers with 35  $\mu$ m copper. The size is 204 mm x 259 mm. The PCB thickness is 1.6 mm. Get in contact with our technical support team to get more detailed information of the layout design and the latest Gerber-files.

Measurements

## 6 Measurements

The following chapter shows some typical measurements made with the EVAL-M5-IGBT7 evaluation board with the IKW40N120CS7 device.

The board was supplied by a 400 V grid and it is connected at the output to a symmetrical RL – load illustrated in Figure 27.

Figure 27 Test load

The value of the inductance is 1.5 mH and the value of the resistor is 30 Ω. With a nominal output current of 5 A<sub>RMS</sub> the output power is about 2.3 kW. The switching frequency was set to 8 kHz and the dV/dt was reduced to max. 5 kV/μs with gate resistors of 27 Ω. The following figure 28 shows the related measurement.

Measurements

### 6.1 Thermal measurements

After the board was powered for around 10 minutes at this condition, the following thermal image was made.
