W164

Spread Spectrum Desktop/Notebook System Frequency Generator

Features

- **Maximized EMI suppression using Cypress's Spread Spectrum technology**
- **Reduces measured EMI by as much as 10 dB**
- **I²C programmable to 153 MHz (16 selectable frequencies)**
- **Two skew-controlled copies of CPU output**
- **SEL100/66# selects CPU frequency (100 or 66.8 MHz)**
- **Seven copies of PCI output (synchronous w/CPU output)**
- **One copy of 14.31818-MHz IOAPIC output**
- **One copy of 48-MHz USB output**
- **Selectable 24-/48-MHz output is determined by resistor straps on power-up**
- **One high-drive output buffer that produces a copy of the 14.318-MHz reference**
- **Isolated core VDD pin for noise reduction**

Key Specifications

Pin Definitions

Pin Name	Pin No.	Pin Type	Pin Description
CPU0:1	22, 21	O	***CPU Clock Outputs 0 through 1:*** These two CPU clocks run at a frequency set by SEL100/66#. Output voltage swing is set by the voltage applied to VDDQ2.
PCI1:6 PCI_F	5, 6, 7, 8, 10, 11, 4	O	***PCI Clock Outputs 1 through 6 and PCI_F:*** These seven PCI clock outputs run synchronously to the CPU clock. Voltage swing is set by the power connection to VDDQ3.
IOAPIC	24	O	***I/O APIC Clock Output:*** Provides 14.318-MHz fixed frequency. The output voltage swing is set by the power connection to VDDQ2.
48MHz	13	O	***48-MHz Output:*** Fixed 48-MHz USB clock. Output voltage swing is controlled by voltage applied to VDDQ3.
24/48MHz	14	O	***24-MHz or 48-MHz Output:*** Frequency is set by the state of pin 27 on power-up.
REF2X/SEL48#	27	I/O	***I/O Dual-Function REF2X and SEL48# pin:*** Upon power-up, the state of SEL48# is latched. The initial state is set by either a 10K resistor to GND or to V_{DD}. A 10K resistor to GND causes pin 14 to output 48 MHz. If the pin is strapped to V_{DD}, pin 14 will output 24 MHz. After 2 ms, the pin becomes a high-drive output that produces a copy of 14.318 MHz.
SEL100/66#	16	I	***Frequency Selection Input:*** Selects CPU clock frequency as shown in *Table 1* on page 1.
SDATA	18	I/O	***I^2C Data Pin:*** Data should be presented to this input as described in the I^2C section of this data sheet. Internal 250-kΩ pull-up resistor.
SCLOCK	17	I	***I^2C Clock Pin:*** The I^2C data clock should be presented to this input as described in the I^2C section of this data sheet.
X1	1	I	***Crystal Connection or External Reference Frequency Input:*** Connect to either a 14.318-MHz crystal or other reference signal.
X2	2	I	***Crystal Connection:*** An input connection for an external 14.318-MHz crystal. If using an external reference, this pin must be left unconnected.
VDDQ3	9, 12, 20, 26	P	***Power Connection:*** Power supply for core logic and PLL circuitry, PCI, 48-/24-MHz, and Reference output buffers. Connect to 3.3V supply.
VDDQ2	23, 25	P	***Power Connection:*** Power supply for IOAPIC and CPU output buffers. Connect to 2.5V supply.
GND	3, 15, 19, 28	G	***Ground Connections:*** Connect all ground pins to the common system ground plane.

Functional Description

I/O Pin Operation

Pin 27 is a dual-purpose I/O pin. Upon power-up this pin acts as a logic input, allowing the determination of assigned device functions. A short time after power-up, the logic state of the pin is latched and the pin becomes a clock output. This feature reduces device pin count by combining clock outputs with input select pins.

An external 10-kΩ “strapping” resistor is connected between the I/O pin and ground or V_{DD}. Connection to ground sets a latch to “0,” connection to V_{DD} sets a latch to “1.” *Figure 1* and *Figure 2* show two suggested methods for strapping resistor connections.

Upon W164 power-up, the first 2 ms of operation is used for input logic selection. During this period, the Reference clock output buffer is three-stated, allowing the output strapping resistor on the I/O pin to pull the pin and its associated capacitive clock load to either a logic HIGH or LOW state. At the end of the 2-ms period, the established logic “0” or “1” condition of the I/O pin is then latched. Next the output buffer is enabled which converts the I/O pin into an operating clock output. The 2-ms timer is started when V_{DD} reaches 2.0V. The input bit can only be reset by turning V_{DD} off and then back on again.

It should be noted that the strapping resistor has no significant effect on clock output signal integrity. The drive impedance of clock output is 25Ω (nominal) which is minimally affected by the 10-kΩ strap to ground or V_{DD}. As with the series termination resistor, the output strapping resistor should be placed as close to the I/O pin as possible in order to keep the interconnecting trace short. The trace from the resistor to ground or V_{DD} should be kept less than two inches in length to prevent system noise coupling during input logic sampling.

When the clock output is enabled following the 2-ms input period, a 14.318-MHz output frequency is delivered on the pin, assuming that V_{DD} has stabilized. If V_{DD} has not yet reached full value, output frequency initially may be below target but will increase to target once V_{DD} voltage has stabilized. In either case, a short output clock cycle may be produced from the CPU clock outputs when the outputs are enabled.

Serial Data Interface

The W164 features a two-pin, serial data interface that can be used to configure internal register settings that control particular device functions. Upon power-up, the W164 initializes with default register settings. Therefore, the use of this serial data interface is optional. The serial interface is write-only (to the clock chip) and is the dedicated function of device pins SDATA and SCLOCK. In motherboard applications, SDATA and SCLOCK are typically driven by two logic outputs of the chipset. Clock device register changes are normally made upon system initialization, if required. The interface can also be used during system operation for power management functions. *Table 2* summarizes the control functions of the serial data interface.

Operation

Data is written to the W164 in ten bytes of eight bits each. Bytes are written in the order shown in *Table 3*.

Table 2. Serial Data Interface Control Functions Summary

Control Function	Description	Common Application
Clock Output Disable	Any individual clock output(s) can be disabled. Disabled outputs are actively held LOW.	Unused outputs are disabled to reduce EMI and system power. Examples are clock outputs to unused PCI slots.
CPU Clock Frequency Selection	Provides CPU/PCI frequency selections beyond the 100- and 66.6-MHz selections that are provided by the SEL100/66# pin. Frequency is changed in a smooth and controlled fashion.	For alternate microprocessors and power management options. Smooth frequency transition allows CPU frequency change under normal system operation.
Output Three-state	Puts all clock outputs into a high-impedance state.	Production PCB testing.
Test Mode	All clock outputs toggle in relation to X1 input, internal PLL is bypassed. Refer to *Table 4*.	Production PCB testing.
(Reserved)	Reserved function for future device revision or production device testing.	No user application. Register bit must be written as 0.

Table 3. Byte Writing Sequence

Byte Sequence	Byte Name	Bit Sequence	Byte Description
1	Slave Address	11010010	Commands the W164 to accept the bits in Data Bytes 3–6 for internal register configuration. Since other devices may exist on the same common serial data bus, it is necessary to have a specific slave address for each potential receiver. The slave receiver address for the W164 is 11010010. Register setting will not be made if the Slave Address is not correct (or is for an alternate slave receiver).
2	Command Code	Don't Care	Unused by the W164, therefore bit values are ignored ("don't care"). This byte must be included in the data write sequence to maintain proper byte allocation. The Command Code Byte is part of the standard serial communication protocol and may be used when writing to another addressed slave receiver on the serial data bus.
3	Byte Count	Don't Care	Unused by the W164, therefore bit values are ignored ("don't care"). This byte must be included in the data write sequence to maintain proper byte allocation. The Byte Count Byte is part of the standard serial communication protocol and may be used when writing to another addressed slave receiver on the serial data bus.
4	Data Byte 0	Don't Care	Refer to Cypress SDRAM drivers.
5	Data Byte 1		
6	Data Byte 2		
7	Data Byte 3	Refer to *Table 4*	The data bits in these bytes set internal W164 registers that control device operation. The data bits are only accepted when the Address Byte bit sequence is 11010010, as noted above. For description of bit control functions, refer to *Table 4*, Data Byte Serial Configuration Map.

Writing Data Bytes

Each bit in the data bytes controls a particular device function except for the “reserved” bits, which must be written as a logic 0. Bits are written MSB (most significant bit) first, which is bit 7. *Table 4* gives the bit formats for registers located in Data Bytes 3–6.

Table 5 details additional frequency selections that are available through the serial data interface.

Table 6 details the select functions for Byte 3, bits 1 and 0.
